SIXTEEN VOLUMES:—CONTENTS OF THE

NINTH VOLUME.—PART II.

N.B.—*THE* Figures *at the* beginning of the line, *correspond with the* N° *at the foot of each* Report; *and the* Figures *at the* end of the line, *refer to the* MS. Paging *of the Volumes arranged for The House of Commons.*

MINES:

[3389.] MINUTES of EVIDENCE taken before the COMMISSIONERS appointed to inquire into the Condition of all MINES to which the Provisions of the Act 23 & 24 Vict. c. 151, do not apply; together with APPENDIX (B.) - - - - - - p. 1

MINUTES OF EVIDENCE

TAKEN BEFORE

THE COMMISSIONERS

APPOINTED TO INQUIRE INTO THE

CONDITION OF ALL MINES IN GREAT BRITAIN

TO WHICH THE PROVISIONS OF THE ACT 23 & 24 VICT. CAP. 151.
DO NOT APPLY,

WITH REFERENCE TO THE

HEALTH AND SAFETY OF PERSONS EMPLOYED IN SUCH MINES.

Presented to both Houses of Parliament by Command of Her Majesty.

MINUTES OF EVIDENCE

TAKEN BEFORE THE

COMMISSIONERS appointed to inquire into the CONDITION of all MINES in GREAT BRITAIN to which the Provisions of the Act 23rd and 24th Victoria, Chapter 151, do not apply, with reference to the HEALTH and SAFETY of PERSONS EMPLOYED in such MINES.

[*For Questions, Nos.* 1 *to* 719, *see Epitome, p* .258.]

REFORM CLUB PALL MALL

LISKEARD.

Tuesday, 15th April 1862.

PRESENT:

The Rt. Hon. Lord KINNAIRD, K.T.
The Hon A. FULKE EGERTON, M.P.
NICHOLAS KENDALL, Esq., M.P.
H. AUSTIN BRUCE, Esq., M.P.
JOHN ST. AUBYN, Esq., M.P.
P. H. HOLLAND, Esq.
RICHARD DAVEY, Esq., M.P.

The Rt. Hon. Lord KINNAIRD, K.T., in the Chair.

Mr. CHRISTOPHER THORPE examined.

720. (*Chairman.*) You are captain of the Wheal Mary Great Consols Mine at St. Neot ?—Yes.

721. Will you state to the Commissioners how many shafts there are in that mine, and the description of the shafts ?—We have four shafts, and we are working on one lode ; but it is a whole mine, and is being worked on other lodes north of the present lode which we are working ; but all the workings down to the 50 fathoms are connected with the old workings.

722. What is the deepest portion of the old part of the mine ?—Eighty fathoms ; but it has not been opened out for ten years below the 50 fathoms.

723. The 50 fathoms is the lowest which you are working at present ?—Yes, below the adit.

724. I suppose there are winzes besides the shaft ?—Yes.

725. Do you use any machine for supplying air ?—Underground, when it is required, we use the small machines.

726. Worked by a boy ?—By boys.

727. Is the mine particularly wet ?—Not particularly wet.

728. What is the height and breadth of the levels which you are now working ?—Seven feet high by four feet wide.

729. I suppose that in the old mine some of the levels are not of that size ?—Some are, perhaps, five feet by two, or perhaps six feet by two or three feet.

730. But you find an advantage in working with the larger size, the seven feet by four ?—The ventilation is better, and there is more room to work.

731. Is it an advantage to the working a mine, independently of the ventilation, to have the levels of the greater size ?—Yes.

732. Is seven feet four the general rule ?—It is what they are generally made now.

733. How many men are there employed working underground ?—The mine, at the present time, is stopped ; it is not working at all now ; it has been stopped since Christmas ; but in less than three months I presume that it will go to work again.

734. How many men had you ?—About 60 underground.

735. And how many women had you employed at the same time ?—It depended upon the production of the ore. Ours is a poor mine, and sometimes we had more and sometimes less ; ten or a dozen sometimes.

736. You had a changing house ?—Yes.

737. Was it at the boiler, or was it separate?—The changing house was separate from the boiler.

738. Was it heated by any flues ?—There is a fire and a flue.

739. What have become of the miners whom you employed ; are they employed in other mines?—They are scattered about; some are in the Carradon district, and some in the neighbourhood.

740. Did they reside in the neighbourhood ?—A good many resided in the neighbourhood.

741. And they have other employment now ?—Yes.

742. In working the new part of this mine was the ventilation good ?—Yes, generally, very good.

743. How was it obtained ; was it from the old shafts ?—The downcast air is from the new shaft ; the upcast is from two of the old shafts. One of the old shafts is on higher ground, and that causes the up cast.

744. I suppose that the men came up and went down by ladders ?—Yes.

745. Have you ever had to do with other mines ?—Not in Cornwall.

746. In what part ?—I have come out of Derbyshire.

747. Have you ever met with bad air in the ends where men have been working ?—Sometimes, if driven too far from a winze, the air gets bad ; it is dead.

748. When that is the case, do the candles show it, or how is it ascertained ?—The candles begin to show it.

749. Do the men report when that is the case ?—Yes.

750. What steps are then taken ?—The machine is put in at once, and after that one of the winzes is put through.

751. But till the winzes get through what is done?—The machines and air pipes are put in.

752. Are the air pipes attached to the machine ?—The pipes are put in where the air is good, and the air is forced in from there by pipes.

753. Are the air pipes made of wood ?—Yes, generally.

754. Do you know what has been the heat in any of those close ends where you have been obliged to put in the air pipes ?—That depends upon the depth.

755. (*Mr. Kendall.*) What description of mine is the Wheal Mary?—Copper and tin ; at one part of the set tin has been got, and copper out of the other part, and tin as well, but not the tin in large quantities.

746. For how long have you had the management of that mine ?—I have been there four years.

757. Prior to that, were you at all used to Cornish mining ?—No. Captain Thomas Richards was the manager, but he has left ; he is now at Hingston Down mine.

758. Did you effect any sales of copper as an agent whilst you were at the Wheal Mary mine ?—Yes.

LISKEARD.

Mr. C. Thorpe.

15 April 1862.

759. To what amount?—About 2,000*l.* a year or 2,200*l.*

760. And how much of tin?—We did not return any tin at all when I was there.

761. You say that you had adits, and that your levels were about seven feet by four; were the lodes large, or did you drive the levels of that size wholly for ventilation?—For ventilation; and it is not more expense to carry a large level than it is to carry a small one. If you get into a close place it requires more powder, and sometimes more drawing away.

762. Is the nature of the ground there hard or not?—It is chiefly hard.

763. What is the expense per fathom?—5*l.* to 7*l.*

764. What is the nature of the ground?—Slate.

765. You have described the shafts as being one down cast and the other up cast; how do you ascertain which is which?—By the draught; the draught goes down.

766. Is it always the same?—Yes; it always goes down from one shaft.

767. There is no variation from that?—Not once in 12 months.

768. Before you came to Cornwall, were you an agent in a Derbyshire mine?—No; I had been in connexion with a mineral agent there.

769. Have you been a working miner at all?—No.

770. You are not a practical man in that way?—No.

771. (*Mr. Austin Bruce.*) How long have you been in this part of the country?—Four years.

772. How long have you been conducting a mine?—Only the four years. I was not sent down to manage the mine.

773. What mines were you conducting in Derbyshire?—Not any. I was merely connected with a mineral agent in Chesterfield who had the management of several mineral estates.

774. What mines were you acquainted with there?—The Wingerworth mines.

775. What mines were they?—Coal mines; the Clay Cross.

776. Do you perceive any difference between the miners here and the miners there, as to health?—I think that the coal miners are the most healthy.

777. To what do you attribute that?—The air is generally better there.

778. Why is the air better?—Because you cannot give the ventilation to these mines which you can to the others; there is not the air forced into the mines here as there.

779. There are no artificial means?—There are no artificial means.

780. Can you, without artificial means, by a proper use of natural means obtain sufficient air to enable men to work under healthy conditions?—Yes, I think so, if you get more shafts, and put plenty of winzes. As soon as you are in an end in the copper mines, if the air is not very good in the end, if you put a winze through to another level, you then have good air at once.

781. According to you, there is no reason why the Cornish miners should not be as healthy as the coal miners in Derbyshire?—Nearly so. It is rather different in the mineral; there is a difference in the rock. I think myself that they get a portion of the rock on the lungs, as well as the bad air.

782. How do they get the rock on the lungs?—Wherever you are working there is sure to be a dust. Take, for instance, any large town where there are many grinders; those grinders never live long, for the very reason that they get dust on the chest.

783. (*Chairman.*) And you have seen dust in any of these mines?—You cannot help it, when you are working.

784. (*Mr. Austin Bruce.*) Are any means taken by the use of water to allay the dust?—In some holes they use water, and others are dry.

785. Have you driven any ends in where the dust has been bad?—No; not where you could particularly perceive it.

786. Are you speaking from what you know, or from what you have heard?—I am speaking what I think about it.

787. But is it what you think from actual observation in the mines, or what you have heard from others?—It is from my observation.

788. You have seen miners working in a dusty atmosphere below; is that it?—No. When you are driving an end, perhaps some of the ends are up, so that you cannot get any water into them, and the dust falls out, and then you are sure to get some dust on your chest.

789. Have you not dust in driving headings in coal mines?—Yes; but the dust is lighter there; it is not so heavy as here.

790. Was your mine a very deep one?—No; the lowest working is now 70 fathoms.

791. The heat was not great?—About 72 degrees.

792. What was the heat of the coal mines in Derbyshire?—That depends upon circumstances; where there is a strong current of air it would perhaps be fifty or sixty degrees, or something like that.

793. What is the extreme heat?—I do not know. If you get near a fire there is a pretty considerable heat at times there; if you get near the furnaces.

794. You say that you can drive the large levels as cheaply as the small ones?—Yes.

795. That is up to a certain point, I suppose?—If you get up seven feet or so, I think that that will do very well. I think that you can drive a level seven feet by four as easily as you could drive one six feet by three.

796. Without more cost?—Without more cost.

797. Did you use much powder in your mines?—Yes.

798. What means did you take to get rid of the smoke after the explosion?—There were no means, except by the machine, or by the natural draught.

799. How long did it take for the smoke to disappear?—For instance, where there is a pretty good draught it is gone away at once; but in an end where there is putting by the machine it takes some time to get it out of the level.

803. How soon did you usually go in after an explosion?—Sometimes half an hour, sometimes a quarter of an hour, and sometimes ten minutes afterwards; it depended upon circumstances.

801. Do you work in an atmosphere impregnated with smoke?—Sometimes; not always.

802. Did you ever observe that the miners were the worse for that?—I do not think that the powder is very good. I should not like to be there long myself.

803. Is there more powder used in these mines than in the coal mines?—They do not use much in the coal mines, unless sometimes they are driving through a rock, to drive one of the headings.

804. You said that you employed about sixty men?—Yes.

805. What was the age of the elder ones amongst those men?—About 50; some were nearly 60, I think.

806. Take fifty miners and fifty colliers, would there be older men at work, as a general rule, among the miners or among the colliers?—I should say among the colliers.

807. Have you ever known men taken ill at their work, and leaving their work, in consequence of working; for instance after a blast of powder?—Never, but one, at our mine, was obliged to leave; but it was not with the bad air that he got his chest bad.

808. (*Chairman.*) What was it with?—He got cold; he got his clothes wet, and was in his clothes a long time, and got wet on his chest, and then he could not stand the smoke afterwards.

809. How did he catch cold; was it after he came to the surface?—Yes. I asked him where he got it, and he said that it was at a mine they called Carn Vivian, a short distance away from us; they had not got a proper changing house there, and they had no fire.

810. It was not at your mine?—No.

811. What was that man's name?—William Gaize.

812. Is he alive now?—Yes, and is working on the mine now. When he could not stand, they put him to the engine.

813. His breathing is still affected ?—Yes ; a little sulphur or anything of that sort would affect him at once.

814. And he could not go under ground ?—No ; I do not think that he could.

815. But he got his cold at another mine, before he came to you ?—Yes.

816. (*Mr. Kendal.*) I understand that you came from a coal district down into this district ?—Yes.

817. With regard to the dust, and so on, did you yourself ever see any dust in a mine while a man was boring ?—Yes.

818. What sort of dust ; was it from the slate or from the copper ?—From the slate, and sometimes from the copper as well.

819. Did you bore dry frequently ?—Not often. At the bottom of the level they put it in this direction (*describing the same*), and they can keep the water in that way, and they draw out the dirt with a kind of spoon.

820. You have yourself seen the dust from the slate whilst the men have been boring ?—Yes.

821. (*Chairman.*) And from the copper ?—It is not often from the copper.

822. (*Mr. Kendall.*) Did you ever yourself feel any sensation of dust in your mouth from the boring, if you have been near ?—No ; it is not perceptible so that you could feel it in your mouth.

823. Did you ever hear any man complain of dust being in his mouth from boring ?—No ; but I believe myself that a good deal of it is from that.

824. How did you manage about setting the ground ?—At so much per fathom.

825. Did you do it yourself ?—Captain Richards used to assist me in doing that.

826. I suppose your experience was hardly enough to enable you to do it yourself ?—I could do it very well ; but he was there, and he did it.

827. Did you ever see any boring of copper in which there was any dust ?—You could not see much dust in the copper ; it is not very often that you bore into the copper.

828. You do not think, in your experience, that they bore into the copper ?—No ; unless the lode is very large.

The witness withdrew.

Mr. JAMES BARKELL examined.

Mr. J. Barkell.

829. (*Chairman.*) You are captain of the South Phœnix Mine ?—Yes.

830. How long have you been connected with that mine ?—I have been there five years the beginning of last March ; but I believe that the mine has been in operation since 1850.

831. Were you ever captain at any other mine before ?—Yes.

832. What other mine ?—The Caylan Mine, in Montgomeryshire, North Wales.

833. Have you ever worked as a miner ?—Yes.

834. What description of mine is the South Phœnix ; is it copper or tin ?—Both tin and copper.

835. What was the mine in which you worked in Wales ?—Lead.

836. How many men do you employ underground at the South Phœnix Mine ?—Twenty.

837. How many shafts have you ?—Only one.

838. What length of levels have you ?—I suppose that our longest drive from the shaft is about 160 fathoms. I am not certain ; you can see pretty nearly upon the plan.

839. What is the greatest depth ?—One hundred and sixty-six fathoms on the under-lie from the surface. Our shaft is diagonal ; we have no perpendicular. We have two air machines working a small shaft.

840. At the surface ?—Yes.

841. How are they worked ?—By a steam machine.

842. (*Mr. Holland.*) Is that a large duck machine ?—They are twisting machines of 20 inches diameter ; those two air machines send in about 400 cubic feet of air in a minute.

843. (*Chairman.*) Do you find that this provides sufficient ventilation ?—Yes.

844. (*Mr. Holland.*) For how many men ?—We have never any complaint of air.

845. (*Chairman.*) Is the air good at those levels ?—Very good indeed.

846. Do the candles burn there ?—Yes ; we never have any complaint.

847. The men have never complained ?—No.

848. Are the engines constantly going ?—They are always working.

849. How do the men ascend ; by ladders ?—By ladders.

850. What is the inclination of the ladders ?—The former part of that shaft was sunk down at an angle of 45 degrees. There are different angles in the shaft.

851. Is this shaft divided ?—Yes ; we have a whim working there, and the shaft is divided.

852. With wood ?—Yes.

853. When the men come to the surface have they a place to change ?—Yes.

853. Where is that ?—They change in the boiler-house.

854. There is no other place to change ?—No.

856. Is there any danger from the boiler-house blowing up ?—We have no appearance of it ; we do not know ; the men have never expressed a fear, and I have no fear in going to the boilers. We have proper safety valves.

857. Is your engine ever inspected ?—Yes, frequently.

858. At any stated periods ?—No ; the engineer comes once, perhaps, in two or three months.

859. Are most of the same men working with you now that worked with you when you first went there ?—Some of them are.

860. Have any been obliged to leave on account of ill health ?—No.

861. You do not know of any men who have suffered from working ?—No, not at all. If they have left it has been because the price which they have had for the ground has not been satisfactory. I have men there who have been working ever since I have been there.

862. And you do not think that the men suffer at all ?—No.

863. Have you any experience of mines elsewhere in this county ?—I have been underground in several of the mines in the county besides the South Phœnix.

864. Have you found in other mines that the ventilation was bad ?—I have found in other mines a natural ventilation ; but ours is an artificial one, as we are obliged to pump our own air.

865. But where it is natural ventilation do you think that that is as efficient as the artificial ventilation ?—I believe that one is as good as the other. If we had 150 men working upon the supply of air which we are giving them we should be short, whereas if there was a natural ventilation it might not be so.

866. A natural ventilation would be provided by having two shafts ; do you think that it would be sufficient if you had two shafts ?—Yes ; it would depend upon the extent of the workings. Two shafts would not be better than one in our place. If the workings were extended a great distance east or west from those shafts they would have to supply them with air by artificial means, as we have.

867. In driving one of these ends is there any dust created ?—We have one end which is driving a good bit from the shaft, but there is no dust, because there is water issuing from it ; but the other is dry, and in cutting it no borer dust arises from that, but only from the bore.

868. Is that in granite or in killas ?—It is all in granite.

869. Do you suppose that it is granite dust which is created by the boring ?—Yes ; it is the dust from the granite rock ; but the dust would not be there after the hole was as big as that you could put your finger in it ; they would then put water, and the dust would be stopped.

870. Have they the means of supplying water

LISKEARD.

Mr. J. Barkell.

15 April 1862.

there ?—The levels are generally kept in, and the water follows them.

871. In blasting is the powder smoke a long time in getting away?—A few minutes ; ten minutes at the outside.

872. That is in this mine where the artificial ventilation is ?—Yes.

873. Would it take longer in other mines, do you suppose, where there was no artificial ventilation ?—No ; I should say about the same time ; it depends upon the strength of the natural ventilation.

874. (*Mr. Kendall.*) As I understand you, you worked in Wales in a lead mine ?—Yes.

875. And you have worked your way up to agency, having been a miner first of all ?—Yes.

876. Did you ever work in the copper mines in Wales ?—No.

877. Was your first connection with a copper mine here ?—No ; I worked as a boy at fourpence a-day in Friendship Mine, about four miles from Tavistock.

878. You have been a practical man from your youth up ?—Yes.

879. When you came to this mine, were you a miner first, or an agent first ?—I was in Spain four years before I went to Wales.

880. After you came from Wales did you come here as an agent direct ?—Yes.

881. What returns have you now from this mine ?—We have none now; we sold one parcel of ore from there in the month of November, and that has been broken little by little, for, I suppose, ten years. We are selling nothing now, and are raising nothing now in the shape of ore ; we are driving to make discoveries.

882. This rapid underlay shaft is in the course of the lode ?—It is on the course of the lode for a certain distance. You see a difference in the angle. It is in the course of the lode as far as 126 fathoms, and a slide came down there, and then the shaft was put down at a certain angle, irrespective of the lode.

883. With regard to the power of your ventilating machine, you say that the air is perfectly good. I see a winze from the 126 fathoms down to the 142 fathoms, but not connected ?—It is not connected.

884. Have any men, since you have been there, ever worked in that winze ?—No.

885. There is no connection there ?—No; there is no communication. That has not been worked since I have been there. We have a communication, as you see in the working plan, between the 100 fathoms and the 126 fathoms. The 80 fathoms is south, and there is a cross course, and then the 126 fathoms is driven the same distance west, and there we have a communication with the 100 fathoms, by a rise ; it is a perpendicular cross course, and can only be shown in that plan by a black speck.

886. What does the 126 fathoms connect with this way (*pointing to the plan*) ?—There is no communication with anything else.

887. As far as your information goes, do you think that before this communication took place the men could work safely there with the machine ?—We have never had any complaints.

888. No men have ever been there ?—Not in that winze, but they have in that level ; and I should say that the air was as good in that winze as in that level. That winze has been full of water, and I have pumped it out twice since I have been in the mine, and have had no difficulty in getting down.

889. Where are the twenty men working now ?—There are four driving at the 166 fathoms ; there are four driving at the 154 fathoms ; six are driving south at the 100 fathoms, in the cross course ; and six are driving south, at the 126 fathoms, in the cross course.

890. And that ventilation answers perfectly ?—Yes.

891. Is the dust which you spoke of entirely from the granite? You have no ore there that you can speak of ?—We have ore, but it is not sufficient to pay the labour of working it, and therefore it is not worked.

892. In your experience as a miner with regard to boring in holes, did you ever see much dust flow from the metal ?—There is always a dust in a dry rock in boring, that I have seen.

893. I am talking of the metal; the lead or copper. From your experience, suppose that a man had a veil over his face, do you think that the dust would fall upon his lip ?—I do not think that he would keep the veil there long.

894. Do you think that the veil would collect the dust there ?—From my experience, it is not necessary to have a veil over a man's face.

895. He would have no dust there ?—He would not have any.

896. (*Mr. Holland.*) Is there ever dust enough in the mine to make a man cough ?—I have never seen it.

897. I think you said that the machine sent you about 400 feet of air a minute for 20 men ?—About that.

898. Is the 166 fathoms level cool ?—Very cool ; the water is so cold that you could scarcely suffer your feet in it.

899. How is the air ?—The air is cold.

900. How long does the powder smoke hang about there ?—Perhaps ten minutes or a quarter of an hour after the blast.

901. And then you can see quite well ?—Yes.

902. (*Mr. Davey.*) What size do you carry your levels ?—Seven feet high, and four feet wide.

903. I see that you have not communicated any winzes from one level to the other ?—We have one communication from the 126 fathoms to the 100 athoms.

904. It is not shown on the section ?—It is not shown on the cross section, but it is shown in the working plan.

905. Are you working at all upon the lode, or only upon the cross cut ?—We are working upon the lode; the 154 fathoms and the 166 fathoms.

906. What size is the lode ?—At the 154 fathoms it is five feet wide ; at the 166 fathoms we do not know the size of it.

907. What is it composed of ?—Of quartz, capels, and mundic, and spots of copper ore.

908. Is there still that rapid underlay ?—Not at the 166 fathoms ; it does not underlay more than about two feet in a fathom at the 166 fathoms.

909. (*Mr. Holland.*) When was this ventilating machine put down ?—One machine was there before I came on the mine five years ago ; the other has been put there since.

910. You put the second one down after the want of it was felt, I suppose ?—The mine was only 126 fathoms deep when I went there, and we have sunk 40 fathoms since, so that we have put down this other air machine to supply the air to the bottom levels.

911. Was it put down as soon as the bottom levels were begun ?—It was put down before, in the course of sinking the shaft.

912. You never tried whether it would do without the ventilation ?—No ; we found it necessary.

913. (*Mr. Fulke Egerton.*) What is the expense of this artificial ventilation; is it an expensive apparatus? —No ; it is merely a 20-inch square cylinder. I should say 6*l.* or 8*l.*

914. £6 or 8*l.* to erect ?—Yes ; the cylinder would cost that, and it would depend upon how far you had got the shaft. We have a perpendicular shaft to put those air machines in of about 20 fathoms from the diagonal shaft.

915. The men go down the mines by ladders?—Yes.

916. Do you find that they suffer much from the labour of coming up or going down ?—No ; it is a very easy footway, in consequence of its being so flat.

917. What is the cost of the working of this ventilation per month ?—That I am not prepared to answer ; it is a little more friction upon our engine. I do not know how much more coals it would cost to work it, but I should say that it would not be much; perhaps a ton of coals in a month.

918. What is the price of coal ?—Eighteen shillings and sixpence per ton is our contract.

919. That is laid down at the mouth of the pit ?—At the engine-house.

920. What is the power of the engine?—About

28-horse power, I should say. On Saturdays we take off the air machine, and connect it again on Monday mornings. I cannot state what the difference of coal would be ; that is the only difference, except that the engine works lighter if the air machine is not attached to it.

921. You do not consider it an expensive apparatus ?—It is very inexpensive.

922. You say that the cylinder cost 8*l.* ?—Yes; I should think that that would pay for it.

923. And then there is the cost of the gearing, the connecting rods, and so on, which is not much, I presume ?—No. The leather has been there for five years, and is never altered. It takes a little grease and oil occasionally.

924. Would you put the whole expense of the apparatus at from 10*l.* to 12*l.* ?—The apparatus, I think, would not cost so much ; the cost of erection would depend upon the situation, how far it was put down from the shaft.

924. (*Mr. Austin Bruce.*) What proportion of the ventilation do you believe to be artificial, and what proportion natural ?—It is all artificial. I do not suppose that we could sink one shaft 30 fathoms under adit without supplying the air by artificial means.

926. Are you a Cornish man ?—No.

927. A Devonshire man ?—A Devonshire man.

928. Are you of a family of miners ?—Yes ; my father was a miner, and I have had nine brothers, all miners.

929. Are they now miners ?—Yes, excepting one, who is dead.

930. Where are they miners ?—One is in Australia.

931. Are the others in this country ?—Three are in Devonshire ; one is an agent at Yarnar Mine, near Bovey Tracey ; two are in Tavistock, and two are at the Lakes of Canada (Lake Superior, I believe), in the mines there ; one is in Australia, and one died of the cholera.

932. Are any of them working as miners in this country ?—The two in Tavistock are working miners.

933. How long were you a working miner ?—From 10 years of age until 21, I suppose.

934. And then you got into a position of trust ; you ceased to follow manual labour ?—Yes ; I went to Spain when I was 21 years old.

935. Are your two working brothers older or younger than you ?—One is older and one is younger.

937. Are they as healthy as you are ?—I believe so.

937. What mines are they working in ?—I cannot tell you ; one was working at Devonborough, and the other at Sortridge ; but where they are working now I cannot say.

938. How long were you in a lead mine in Wales ?—Yes ; for three years at Caylon in Montgomeryshire.

939. Did you observe any difference in the mining population there and in Devonshire and Cornwall, as far as regards health ?—We had all natural ventilation there; the levels were driven in the sides of the mountains; we have no workings under the base of the hill.

940. You have not answered my question ?—Their health was good ; I do not know that they suffered anything.

941. I asked you whether you observed any difference between their health and the health of the Devonshire and Cornish miners ?—Not at all.

942. Do you consider the Cornish miners to be a healthy race ?—I cannot speak of the Cornish miners; only those that I know. I know about the miners in this district ; they are healthy.

943. Do you think that they are as long lived as those who work upon the surface of the ground ?—I cannot say that ; I do not know that they are.

944. Are they as healthy in appearance ?—Yes.

945. Do you think that they continue to be able to work as long as men who work above ground ?—I cannot say.

946. Have you had many men leaving you on account of consumption or from failing health ?—I never had one who left since I have been an agent.

947. How many hours a day would the men work in the deepest part of your shaft ?—The same as they would in the shallows; eight hours.

948 At the end of that time, in what state were they when they left the pit ?—They were fit to work another eight hours, and they have done it frequently. If there is anything amiss with one of their colleagues, and he does not come, they take a bit of something to eat, and go down and work another eight or nine hours.

949. That is the state in your pit. Have you been in the neighbouring shafts ?—I have been underground in several mines, and I believe that that is the state in most mines in which I have been.

950. You have been, I suppose, a good deal in the company of the working miners ?—Yes.

951. Have you ever heard from them any complaint as to their health being affected by the nature of their work ?—No.

952. Are no coughs attributed to it ?—Not that I know of.

953. Have you a doctor connected with your shaft—?We have a doctor at the mine, and our men pay to the doctor.

954. How is he paid ?—We charge for doctor and club 1*s.* 6*d.* a month ; the doctor has 9*d.*, and for the 9*d.* he renders medical attendance to the man and his family.

955. What is the name of your doctor?—John Jago.

955*a*. Where does he live ?—At Liskeard.

956. (*Chairman.*) Does the doctor only attend in case of accident, or does he attend in case of illness?—He attends in all cases when he is sent for. If anything is the matter with any of the family they send for the doctor.

957. Does the 9*d.* a month include the wife's confinement and all ?—No.

958. Only illness ?—Sickness in the family. There is a club, and we take 1*s.* 6*d.* out of the men's monthly gettings for the club and doctor.

959. (*Mr. Holland.*) They pay 1*s.* 6*d.* a month and they get 4*s.* 6*d.* a week when ill ?—Yes, with medical attendance.

960. They pay 9*s.* a year to the club ?—Yes.

961. And they get 4*s.* 6*d.* a week when ill ?—Yes.

962. Then you reckon upon their being ill a fortnight in a year ?—We do not make any such calculations.

963. (*Chairman.*) Am I to understand that the 4*s.* 6*d.* is allowed to them for any casual illness not connected with working in the mine ?—If a man was sick from any other cause, if he had not been working in our mine more than a week, he would have 4*s.* 6*d.* a week and medical attendance as long as the mine worked.

964. (*Mr. Austin Bruce.*) Do you pay him out of the fund, or are you responsible to him for 4*s.* 6*d.* a week ?—It would be charged in the cost of the mine. I do not keep the books. I do not know how the funds of the doctor and club would stand, but I know that I should charge that money.

965. (*Mr. Kendall.*) As I understand, it is this ; that supposing the fund of the club is not rich enough to pay, still the miner gets his money ?—Yes; the company would pay it.

966. Is there generally a balance in hand in favour of the fund ?—I am happy to say that we have never had a test ; we have been very fortunate in our club; we have not had much sickness in it.

967. (*Chairman.*) Supposing the mine to stop, that 9*d.* which the men have subscribed would belong to the shareholders of the mine; it would not be redistributed to the men ?—There would be nothing refunded to the men.

968. (*Mr. Kendall.*) As I understand you, you have had nine brothers who have been miners, and you have worked your way up as a miner ?—Yes.

969, And you have all your brothers living now, except one who died of the cholera ?—Yes.

970. Some are working men now, and some are agents ?—Yes.

971. What is the age of the oldest and of the youngest ?—The oldest I should say was about 48, and the youngest 25.

972. What is the man who is 48 ; is he used up, or is he able to work still ?—He is not used up: he is one of the men working underground.

LISKEARD.

Mr. J. Barkell.

15 April 1862.

973. And is he healthy and strong ?—Yes.

974. When did you see him last ?—About two months since.

975. Is he working on tribute or on tut work ?—He is working at tutwork; he had a boy working with him.

976. Are you at all aware of his average gettings in the last 12 months ?—No.

977. Is either of your brothers weak ?—Not that I know of.

978. (*Chairman*). You say that there is a payment of 4*s.* 6*d.* a-week, whether the men be injured, or whether they be ill ?—Yes.

979. How long do you continue to pay them, supposing that it is a long illness; is there any limit ?—There is no limit.

980. You would pay a man for years if he continued ill ?—Yes.

981. Is it usual to have no limit ?—I never knew any limit in mines. Of course if his illness was brought on through his own seeking the money would not be paid to him at all; if it was brought on through wrestling, or any such things, we should not pay him; but if it was a natural sickness we should pay him.

The witness withdrew.

Mr. W. Richards.

Mr. WILLIAM RICHARDS examined.

982. (*Chairman.*) With which mine are you connected ?—West Sharp Tor.

983. You are captain of that mine ?—Yes.

984. How long have you been engaged at that mine ?—A little over twelve years.

985. Were you employed in any other mine before this one ?—Not as an agent.

986. Have you worked as a miner ? — Yes, at several mines.

987. At what age did you begin to work ?—Between eight and nine.

988. And you have worked your way up to your present position ?—Yes.

989. Have you worked in any other mines in Cornwall ?—Yes.

990. Were all the mines in which you have worked in Cornwall ?—No; two were in Devonshire.

991. Is your present mine a copper or a tin mine ? —It is copper.

992. And it has been working twelve years ?—A little over twelve years.

993. Did it only begin working when you came, or was it an old mine resumed ?—It was a young mine just commenced when I went there.

994. What is the depth of the shaft ? — It is 162 fathoms, partially worked. (*The witness exhibited a section of the mine to the Commissioners.*)

995. You have two shafts ?—Yes.

996. And the deepest is 162 fathoms ?—Yes.

997. What is the greatest length of a level from one shaft ?—About 120 fathoms.

998. Is it working at the present time ?—Not at present; it is in abeyance for a time.

999. That is connected with the two shafts ?—It communicates with them.

1000. What is the greatest length of level at which men are now working ?—The 162 fathoms; all our force is concentrated to those points for the present.

1001. What number of men have you ?—We have eighteen miners at present. There are three in the ends, but there is a cross cut; there are two men at each.

1002. But they change ?—Yes.

1003. Have you any means of ascertaining what the heat is there ?— We have no means at present, but it is very good; the heat is only the ordinary temperature; it is close to an engine shaft.

1004. The ventilation is good there ?—Yes, it is close to the engine shaft.

1005. And that is divided into two parts ?—Yes.

1006. And the ladders are at one part ?—Yes. The engine-rod is shown as far as this (*pointing to the section*), and below that there are rods, and the division would be about here (*pointing out the same*).

1007. What is the extreme length of the end at the bottom from the shaft ?—About five fathoms; it is shown off a little bit there beyond the actual length.

1008. You say that you have worked from the commencement of this mine ?—Yes.

1009, When you were driving this level, marked here No. 70, had you any means of ventilation before you reached the other shaft ?—Yes.

1010. Artificial or natural means ?—It was a waterfall; a spring of water which used to issue from a portion of the shaft about here (*pointing to the section*), and then we concentrated it into a cistern, and forced on the air by the fall of the water in zink pipes conducted through the level.

1011. So that no inconvenience was felt by the men working there ?—Not at all.

1012. How far did you drive this level before you applied this artificial means ?—Just eight or nine fathoms. We applied it at once, because we could avail ourselves of it at once.

1013. Of what size was the zinc pipe ?—Five inches diameter.

1014. And you found that perfectly sufficient ?—Yes.

1015. What was the cost of that ?—It was only the cost of the pipe; it was 2*s.* 4*d.* per fathom.

1016. When you drove the ninety fathoms, did you apply the same means ?—That was communicated previously to commencing that, and therefore we availed ourselves of the same apparatus.

1017. In driving the 110 and 125 did you use the same means ?—Yes. These points were dispensed with, and we therefore applied it to those deeper parts.

1018. You only worked one of these at a time ?—Just so.

1019. Do the men ascend by ladders ?—Yes.

1020. Do they suffer by ascending from ladders ?—I should think very little indeed.

1021. How long does it take them now to ascend ? —Between five and ten minutes. There is only 60 fathoms. The 100 fathoms is at an angle of 43 degrees, and therefore it is rather an acute angle, and is therefore easy.

1022. When the men ascend to the top, have you a changing house ?—We have a changing place.

1023. Where is that ?—It is in the boiler-house, by the side of the boiler.

1024. Would it not be better if there was a changing house as well ?—I think so; but the probability is, that the men would prefer the present place. I am of that opinion because the temperature is warmer.

1025. Have you ever seen any changing houses which are heated ?—I have.

1026. Do you think that is an advantage ?—In some cases.

1027. I suppose that that is the case when there are a great number of men ?—Yes; when the men are numerous I think it probable that they would prefer a little more room. We have only six men at a time.

1028. You have worked in other mines ?—I have.

1029. Large mines ?—One very large mine, the Devon Great Consols, in Devonshire.

1033. Have you worked in any large mines in Cornwall ?—Not in any very large mine in Cornwall.

1031. (*Mr. Kendall.*) Are most of the men whom you have working now young men, or are some of them old men ? — Some of them are young, and some old, that is to say, moderately old; perhaps the oldest man would be 45, and there are some as young as 22; from 22 to 45 would be, perhaps, about the average.

1032. You have worked in a great many mines; what is your experience with respect to the miners; when do they begin to fail in their strength ?—In my experience I have not seen sufficient to answer that question exactly.

1033. You have worked as a tributer yourself, have you not ?—I have.

1034. And you have worked as a tut-workman ?—I have.

1035. I suppose you picked out your comrades when you used to work ?—I have always done so.

1036 At what age do you generally look shy at a man as a comrade ?—I should have no objection, if I was young, to work again to-morrow, to take a man of 40 years of age.

1037. Would you go beyond that ?—Yes, in some cases. In very many instances, I might say, it would depend upon the mine in which he was going to be employed.

1038. With regard to dust, I suppose you have bored in copper, and in tin, and in granite, and in killas or slate ?—I have.

1039. Did you, in your experience, ever see the dust arising in the boring ?—I have witnessed a little occasionally.

1039 *a.* In which ?—In all kinds.

1040. In boring for copper, have you witnessed any dust of any moment ?—I have a little.

1041. To what extent have you seen it ?—I may say a very little ; it would be just by taking in the back of the end.

1042. Where you are obliged to reach up ?—Yes ; close to what we call squaring in the back.

1043. Do you think that there is so much dust that the men breathe that dust ?—I think it is probable that they inhale a little.

1044. Did you ever hear any man complain of it as being injurious ?—No complaint is ever made. I never made any complaint at the time, and I never heard my comrades make any complaint at the time.

1045. Still, there might be injury without complaint ?—I think it is possible that there may be a little injury done, but very little, I should say.

1046. (*Mr. Davey.*) Did you ever feel any inconvenience result from this dust ?—To say that I never felt any inconvenience, I think perhaps that would be wrong, but very little in my experience.

1047. How often, in the course of a week or a month, might it occur that the men would be working in the end so as to produce that dust ?—Probably four times a month, when there would be just a little inconvenience.

1048. But in any other part of the end there would not be dust ?— There is water applied to check it.

1049. What is the produce of the mine where you are ?—Copper. The mine which I have just been speaking of is the Devon Great Consols. At the present time we get a little copper occasionally ; that is the object ; we have raised just a few tons.

1050. (*Mr. Kendall.*) How much have you sold ?—None.

1051. And you have been working 12 years ?—Yes.

1052. You are still in hopes ?—Yes.

1053. (*Mr. Davey.*) What sized lode is the 162 fathoms generally ?—Thirty-two feet wide.

1054. What is it composed of ?— Iron, quartz, a little copper, a little mundic, and a little fluid of lime, and so on.

1355. Of what width do you carry the levels ?—Seven feet high and five feet wide.

1056. (*Chairman.*) Have you had any accidents occur from blasting ?—We have only had one during the 12 years.

1057. How did it occur ?—It was through the carelessness of the man ; it was a premature explosion.

1058. Was it from his going back too soon ?—It was from the carelessness of inserting into the hole the tamping before he had properly cleaned out the hole, and taken out the few grains of powder on the side of the hole; what we call the swab-stick.

1059. What kind of fuse do you use ?—The best in the country ; from Bickford and Company.

1060. Is the smoke a long while clearing away after the charge has been fired ?—No ; a very little time elapses before we can go at the work again.

1061. I suppose that the men are anxious to see the result, and sometimes go in before the smoke has cleared away ?—Yes, there are such occasions ; sometimes they are very anxious, but in the majority of cases they wait a proper time.

1062. Are the borers made of steel ?—We use steel.

1063. (*Mr. Austin Bruce.*) Did you begin as a working miner ?—Yes.

1064. How long were you a working miner?—Fifteen years.

1065. Did you ever suffer yourself ?—I cannot say that I have suffered anything very direct. I do not know. I may have partaken probably of a little injury from bad ventilation. I do not know. I cannot say that I ever did ; it is possible that I may have done so.

1066. We have heard something of a cough which the miners are said to have ; have you ever had it ?—I do not know whether I may have had what they term the miner's cough. I think not myself.

1067. Have you observed any of your fellow workmen suffering from it ?—I think not, in my experience.

1068. Have you known many of them obliged to give up their work under ground early in life ?—I have some few; very few.

1069. Do you know to what cause that was owing ?—I cannot say that I can attribute it to any particular cause.

1070. How long have you ceased to work yourself ?—A little over 12 years.

1071. Do you believe that if you had continued working underground you would have been as healthy a man as you are now ?—That would have depended entirely upon circumstances. I am sure I do not know how I might have been placed.

1072. You mean by that, that it would have depended upon whether you worked in a well ventilated mine or in a badly ventilated mine ?—Yes.

1073. Have you ever worked in an ill ventilated mine ?—I never have.

1074. Have you ever been working in a mine parts of which were ill ventilated ?—Never.

1075. Have you ever had any experience of workmen who were working in badly ventilated mines ?—No; nothing of the kind has ever come under my notice.

1076. What is the deepest mine that you ever worked in ?—The one which I am now engaged in is the deepest mine that I have been connected with ; but I have been underground in deeper mines.

1077. Have you ever suffered at all from ascending and descending by ladders ?—Not myself, that I am aware of.

1078. Have you ever seen others suffer from it ?—Not to the best of my belief.

1079. Do you believe that after a hard day's work a man can mount 300 fathoms, and be no worse for it ?—I should think it was possible that he would be the worse for it.

1080. But you have not yourself seen any instances of it ?—No ; no case has come under my notice of any particular complaint.

(*The witness explained the working plan of the mine to the Commissioners.*)

The witness withdrew.

Mr. THOMAS TREVELYAN examined.

Mr. T. Trevelyan.

1081. (*Chairman.*) I believe that you are the captain of Herodsfoot Mine ?—I am.

1082. Will you state how many hands you employ altogether at that mine ?—We have 70 men under ground, and about 50 labourers at the surface ; men, women, and children.

1083. What number of shafts have you in the mine ?—We have four shafts.

1084. What is the deepest ?—150 fathoms from the surface.

1085. What is the length of any ends from either of these shafts at which you are now working ?—From our two main shafts there is about a distance of 300 fathoms.

1086. You have not a plan of your mine with you ?—I have not. There are about 300 fathoms from the two extreme shafts ; the other two shafts are intermediate ones.

1087. What means of ventilation have you ?—We have extraordinary ventilation just at this time; very good indeed.

LISKEARD.
Mr. T. Trevelyan.
15 April 1862.

1088. Natural ventilation ?—Quite so ; we have nothing else in the mine.

1089. Are there any winzes ?—We have not winzes, particularly ; our lode is a north and south course, and we are working one part of the lode south ; we are driving all our levels south ; we are driving five levels south, and we have been fortunate enough to take away all the ground for the last five years, consequently the air traverses down through the different levels; it goes down, and goes back through the north levels, and up the shaft.

1090. Do you know what is the greatest heat ?—I have never tried the barometer, but it is very good.

1091. So that such a thing as that a candle will not burn never happens ?—No.

1092. And there are no complaints from the men of bad air ?—No, not at all.

1093. How do the men ascend and descend; is it by ladders ?—Yes; they climb.

1094. Are those ladders perpendicular, or are they on a slope ?—Our sumpt shaft is perpendicular to the 70 fathoms, and then we sink from the 70 fathoms to the 150.

1095. The men come up different shafts ?—Yes; they come up the south shaft where our levels are now. We are now sinking perpendicular, and that is a new shaft, and that shaft is down to the 80 fathoms.

1096. Do the men prefer coming up one shaft more than the other ?—The men at the bottom levels come up the sumpt shaft, and those working near the south shaft, where the shaft is down to 80 fathoms, come up that way ; it is a matter of choice ; they may go either way.

1097. Is it not very fatiguing to come up the ladders ?—Of course it is fatiguing.

1098. When they arrive at the top are they usually blown ?—No ; they generally manage to take their time; they do not force themselves to that extreme; there is no such compulsion.

1099. Do none of the young men ever try to race up ?—No. It is certainly fatiguing and hard work to climb ladders. I have experienced it myself almost daily, but we were not bound to exert ourselves to such an extent as to exhaust ourselves.

1100. The men never complain of suffering from bad air ?—No.

1101. Do they ever catch cold in coming up ?—Not that I am aware of.

1102. You have a changing-house ?—Yes.

1103. Is that at the boiler, or is it separate ?—We have a house distinct from the boiler-house, which was built distinctly for them to change in ; it is optional on their part ; sometimes they prefer the boiler; we do not interfere with them. The quality of the boiler is very good, and consequently they venture to go there. When it is very warm they might go to another place.

1104. You say that "they venture to go there;" is there any danger ?—There must be danger connected with it where there is steam, but we do not suppose that there is any great danger.

1105. But there is danger of the boiler bursting ?—Of course there is no certainty at any time where there is high-pressure steam.

1106. Have you ever known a boiler burst ?—Yes.

1107. In these works ?—Yes.

1108. Was there any loss of life occasioned ?—A man was retreating from that boiler-house; the engine was not working; we do not work it by night; we work it in the day. The steam was got up in the morning, and some men were changing there, and the engine-man had not commenced working, and he had got the steam rather higher than it ought to be. The men had left the place, and this poor man had left also, as they thought, but the steam was buzzing up rather fast, and he wanted to go back ; his comrades did not want him to rush back while the steam was rather high, but he went back, and in retreating again the boiler burst ; the engine was not working.

1109. If there had been more men working in the boiler-house at the time, the loss of life might have been serious ?—Of course it would have been ; a boiler cannot burst without doing damage if men are there.

1110. Then you think that it would always be safer to have a separate changing-house ?—Yes; we have one now ; but the men will go to the boiler-house again.

1111. Is the changing-house which you have heated at all ?—No.

1112. It is not a drying place ?—We have no fire put into that house ; ours is a very dry mine; we have no water; the men are always dry, and by putting their clothes upon the boiler, and changing there, we find it quite sufficient.

1113. I suppose that when men come up very hot, and in cold weather, it would be an advantage that the changing-house should be warmed or comfortable ?—They are very close; where they come up the footway they are there immediately.

1114. The footways are close to the changing house ?—Yes.

1115. You have more than one changing-house ?—Yes; we have another in the south part of the mine where the men connected with the shaft change ; we keep a fire there night and day, because the men working in the shaft require to dry their clothes.

1116. They get their clothes wet ?—Yes. A house is especially set apart for themselves.

1117. I suppose that you have worked in other mines?—Yes; I have been a miner thirty years.

1118. Have you been down other mines since you have left off working in them ?—Yes.

1119. I suppose there are other mines in which you find that the ventilation is not so good as in your own mine?—Yes. I have seen mines which are not so well ventilated, and it is impossible to keep all mines perfectly ventilated at every point.

1120. You mean that when they are driving an end away from the shaft the ventilation must be bad ?—Yes. Sometimes objects are to be accomplished, and points to be proved, before we can bring down the ventilation which we might desire ; I cannot say that at all times perfect ventilation exists in every mine.

1121. In any mine in which you have worked or which you have seen are there any artificial means used ?—I have seen artificial means.

1122. Did they seem to you to answer ?—They seemed to answer very well. I suppose that the air is not so good as the natural air. I question that, and it is not believed that it is so good ; but still it is a great assistance.

1123. What are the artificial means which you have seen ?—Sometimes the air is forced with fans, with waterfalls, and sometimes it is done by fans worked by boys forcing it in, causing a rush of wind, and it is conveyed in by a close pipe.

1124. I suppose that that ventilation is not brought direct from the surface, but is taken from any shaft or opening, and is forced in ?—Yes.

1125. Have you ever seen a machine at the surface ?—Yes; a kind of fan there, to pour air down the shaft.

1126. In driving the sbaft, do they take any means of dividing the level ?—We have never done so; I have never seen a level divided.

1127. Something like what is called in the coal mnies brattice work?—No. We divide, of course, our engine-shaft, but not purposely for the air.

1128. One part is for bringing up the material and the other for going down ?—Yes.

1129. Does dividing a shaft make a current of air ?—Yes ; when it is divided it does assist.

1130. Would it not be possible to have a temporary division in the level in which you were working, so as to form a current ?—I cannot tell. When the air traverses in to a certain distance, it does not always come in from the shaft ; the air might come in from the top levels, and circulate right through the levels.

1131. You have never tried the dividing of a level to form a current ?—No.

1132. Have you ever known the men complain of ladders ?—No, never.

1133. Do you know in Cornwall what is called the miner's disease ?—Yes ; I have heard so many statements respecting miners hardly living at all that I have taken the ages of all our men, which I am quite

willing to submit to you. I have put down all their names and ages, and struck an average. I have been in the mine eleven years.

1134. In this same mine?—Yes. I have the name and age of every man taken down, from the youngest to the oldest, and we have only had two deaths in eleven years, (*producing a paper*).

1135. Are these both surface and underground men?—No; there are no surface men there; those are all underground men.

1136. I see that fifty-four is the greatest age?—Yes, there are two of the age of fifty-four; the youngest is eighteen.

1137. Are there any boys?—I have none less than eighteen, and only two at that age.

1138. Is that because you do not allow them to go down, or because you think that they cannot work sufficiently?—I prefer men.

1139. As more efficient workers?—Yes.

1140. Are there any of these men that you are aware of who complain of shortness of breath?—Not one; I do not know an individual among the lot who does so. There are seventy men, who average from fifty-four down to eighteen, the average being thirty-two and two months.

1141. During the eleven years, how many accidents have there been?—Two.

1142. What did they occur from?—The first was a young man killed by a piece of ground turning out at the bank of the stope. I only passed the stope five minutes before he was killed. It was a projecting rock, and I had no sooner gone over the stope than it proved that those two rocks were what we call a-head; they were fast together by the head, so that the weight came over, and came down upon the young man, and killed him instantaneously. The other death occurred through a man slipping in descending, and he was killed.

1143. There is always a chance of falling away from the ladder?—Yes, and sometimes a short distance might kill a man, depending upon whether he pitches upon his head or otherwise.

1144. The steps of the ladder are made of iron, are they not?—All iron.

1145. Is there any periodical inspection of the ladders?—We keep a man to examine all the timber-work daily; he is kept purposely for that.

1146. You have never had any accident from men being careless in blasting?—Never.

1147. Have you certain rules laid down for them?—We have rules, and I take upon myself at all times to give them advice to be cautious, and mind what they are using, and we have been very fortunate, and have never had an accident in blasting.

1148. But do you think that unless the men are properly advised and looked after they become careless in blasting?—They are tolerably considerate and thoughtful men; they know what powder does; and knowing the results of powder, they know that they are dealing with a very important ingredient.

1149. In this mine you have never had any foul air to contend with?—No.

1150. Have you worked in other mines?—Yes.

1151. In Cornwall?—Yes; I was from Camborne originally. I worked in Dolcoath 25 years ago, 200 fathoms deep, before they took up the lifts; they have put them down again now.

1152. Have you ever seen a man engine?—Never; I have never been in those mines where they use a man engine.

1153. Are there any mines in Cornwall that you know of where the men are taken up in skips?—I have never seen it; I know the names of the mines, and that is all.

1154. I believe that there are such mines?—I have heard so.

1155. Do you not think that it would be an advantage for the men to be conveyed up by some means, instead of having to climb?—We must admit that it is a great assistance, and a very comfortable passage, instead of climbing.

1156. Do you suppose that there is any difficulty or objection to carrying out properly these means?—There are great difficulties to contend with, if we go into the general question. We cannot put man-engines and shafts for every mine, just where people may imagine. They are plausible things to talk about, but difficulties will occur.

1157. How many women are employed at your mine?—We have six little girls, just for picking, and that is all.

1158. You have none for breaking?—No; we keep men for that.

1159. Is it men who have given up working underground who take that work?—No; we have not an old miner on the floors; they generally come from the class of agricultural labourers, and finding that we give, probably, a little higher pay than they would get as agricultural labourers, they come to us, in order to benefit themselves.

1160. You give higher pay than the agricultural labourers receive in the neighbourhood?—Yes.

1161. What is the pay of a surface man, generally?—2*s.* a-day.

1162. What do the pit workmen earn generally?—Our man strike on an average about 3*l.* 12*s.* 0*d.* per month.

1163. And, of course, the tribute men you cannot found an average upon?—No; but we have no tributers in our mine.

1164. Is it all done by tutwork?—Yes.

1165. The taking out of the ore?—Yes; we take out all the ore on tut-work.

1166. In your opinion is that a more satisfactory way of working than as tributers?—I am better pleased with it. Perhaps, under some circumstances, tribute would be better than tut-work, in some mines; but having north and south lode, and only one lode in our mine, and being tolerably rich in silver, lead, and so on, we think it better to have it under our own control, and to have no tributers mixed up with it.

1167. (*Mr. Kendall.*) Your mine has been a profitable mine for some time, has it not?—We have been paying a fair profit for the last four or five years.

1168. You have been the head agent there for a long time, have you not?—I have been an agent there eleven years, but not the head agent. I have been manager of the mine for the last three years.

1169. Have you found the adventurers always ready to follow out any of your suggestions for the benefit of the miners?—At all times.

1170. Then if you thought that a dry was necessary, and suggested it, you have no doubt that they would carry it out at once?—Yes. I have built a house, but a fire has not been put in.

1171. But they would not mind the expense of a fire?—I think not; or if the men asked for it I would put it there.

1172. It is a very rare thing to take away so much of the lode as you do?—Yes, very rare; but we have taken away almost the whole of it for the last seven years.

1173. You have better ventilation there than in most mines?—Yes; owing to that.

1174. Take your own mine, and take other mines, do you think that your miners, as a body, are more healthy than in other mines?—I am hardly justified, perhaps, in contrasting my own men with other parties' men; perhaps it would not be fair for me to pass any remarks upon others; it would be illiberal.

1175. You are satisfied that your men are up to the average?—I am very well satisfied with my own men.

1176. With regard to the club, what do you allow them per month, when they are ill?—1*s.* a-day, hurt pay; 30*s.* per month.

1177. If they are consumptive, or anything of that kind, and have been with you a long time, what do you allow them?—We have no private fund for sickness.

1178. You confine it to accidents entirely?—What we term hurt-pay.

1179. Do you give them anything in the way of

LISKEARD.
Mr. T. Trevelyan.
15 April 1862.

wine, or what they require ?—Yes ; our late manager was very well for that. When a man had a bone broken, perhaps his arm, or any thing of that sort, he was always allowed a little animal food, and something extra, to restore him again.

1180. What do you deduct per month for the doctor and club ?—One shilling and sixpence.

1181. Is not that the usual run throughout the whole of the county ?—I think so. We have been paying poor rates in Lanreath for the last eleven years, and not one of our men has had relief from that parish. I can say that with propriety. I told the farmer so the other day. We are rated at 140*l.* a year.

1182. You are rated upon the lord's dues ?—Yes ; of course that would fluctuate.

1183. Do they rate you up to the full ?—Sometimes we go down, and sometimes we go up ; we take it on the average ; it would be higher sometimes, and sometimes perhaps it would be low ; but we entered into a fair arrangement. I do not know that we ought to pay any poor rate, because we pay individually.

1184. (*Mr. Holland.*) You have no boys working in your mine ?—Not underground, under 18.

1185. Is it usual for boys under 18 to work in the mines ?—Yes ; many boys in the county work at a less age than that.

1186. The absence of any boys in the mine of course makes the average age higher than usual ?—Then we have not very many old men. If we had many old men it would help out the youth.

1187. Have you the ages of those working above ground ?—No. They never have been down the mine, and I thought it immaterial to bring the ages of the surface labourers. I thought that it would be most satisfactory to you to see the ages of the underground men, as much had been said about their not living long.

1188. You said that only two had been killed in your mine in 11 years ?—That is the time that I have been there. This month will make my 11 years as agent.

1189. Have you employed about the same number during that time ?—About that.

1190. (*Mr. Davey.*) You said that you attributed the goodness of the air in your levels to the stopeing of the ground ?—That was a considerable improvement.

1191. Do you stope from the back ?—Yes ; and drive levels.

1192. What is the price ?—About 2*l.* per fathom.

1193. Do you never use powder ?—Yes, sometimes. We should sometimes have a little to relieve the hard part, and we should then blast the hard part. Sometimes our lodes are six feet wide, and mixed up with the stuff which we send up to the surface ; it is sometimes perhaps eight feet wide, and sometimes it drops down to two feet, and sometimes to one.

1194. Taking the lode ; it is not very rich ?—No ; it is tradgy.

1195. Have you ever worked in any other lead mine ?—No ; but I have been agent in another lead mine.

1196. Are you aware that lead mines generally have worse air than tin or copper mines ?—No; I am not aware of that. I know all the lead mines in the district.

1197. (*Mr. St. Aubyn.*) Is it not very unusual for a mine to be so dry as yours ? You said that you had no water ?—I did not mean to say that we had no water ; but I say that the places where the men are working are dry.

1198. You look after your men a great deal, by your account ; you take care of their health ?—I do not wish to boast of doing anything. I do the best I can do for the men, of course.

1199. In fact, they are well looked after ? — I think so.

1200. You say that the average age is 32 and two months ; are you aware of any other mine in your neighbourhood where the average of the miners' ages has been taken ?—No ; I have never seen or heard anything about it.

1201. You can only form a guess as to whether your average is better or worse than in other mines ? —I did not know our average before I took down the names and ages. I do not know at all about other mines. I do not know the individuals who work in other mines. I have seen the mines, but I do not know the men.

1202. You consider your mine to be a very healthy one ?—I do ; I am perfectly satisfied of that.

1203. (*Mr. Austin Bruce.*) Do you believe that every mine throughout the district is as well ventilated as yours ?—I think that the mines in this district are very well ventilated, as far as I have seen of them, and I have seen the majority of them.

1204. Yours is a silver-lead mine ?—Yes.

1205. Have you ever worked in copper mines ?—Yes.

1206. In the copper mines in which you have worked has the ventilation always been as good as in the mine which you now manage ?—Yes, I think very good.

1207. Have you ever heard the workmen complain of working in close ends with insufficient air ?—Yes, I have heard that.

1208. Have you ever seen workmen who were so working ?—Yes.

1209. Have you ever seen them at all the worse for it ?—I have heard them complain that their place was a close air place, and so on, and that when they shot the smoke would be rather unpleasant, and so on. As I stated just now, it is a matter of course, sometimes, and you cannot prevent it. When you want to accomplish an object you cannot always command the ventilation which you are fortunate enough to gain, provided that you have a mine where you can work well, and can carry out your objects.

1210. You cannot get good natural ventilation in a close end ?—You cannot, sometimes.

1211. But you can always introduce artificial ventilation ?—Perhaps you might.

1212. Have you ever seen the close end into which you could not not have introduced sufficient ventilation if you had been told to do it ?—I do not think that I have ever seen an end but what you could carry artificial air into, provided that you could be furnished with the means.

1213. It is a question of expense ?—It is a question of expense, sometimes.

1214. You have lived all your life in this district, have you not ?—Not in this district.

1215. In this county ?—In this county.

1216. Do you mean to say that during that time you have never come across sets of men working in close ends who appeared to be suffering from their work ?—No.

1217. Have you never seen men working in high temperatures who were obliged to work short hours ? —Yes, I have seen that.

1218. And in those cases were the men none the worse for it ?—Of course it must be hard work, and it must tell upon their bodies when they are working in very hot places and in very deep mines.

1219. Have you never known any ill consequences arise from working in those places ?—I have no manner of doubt about it, but none have come under my personal observation. I have not the least doubt that such is the fact.

1220. What is the exact depth of your shaft ?—One hundred and fifty fathoms.

1221. How long would it take, without forcing, for a man to get from the top to the bottom of the ladder ?—About half an hour.

1222. If it was twice as deep he would take rather more than twice as long ?—Of course he would.

1223. And there are many shafts twice as deep as yours, are there not ?—I suppose there are very few in Cornwall 300 fathoms deep.

1224. Have you ever worked in any mine in which

you think that the men would have been able to work longer if they had had man engines instead of ladders to mount at the end of the day?—I do not know that I have; I do not know that any thing of that kind has crossed my mind, but I have no doubt that where a man engine is applied it is a great relief to the men working in those mines.

1225. When you say "a great relief" do you mean a great saving of strength and health?—I should think so.

1226. Do you think that there is any difference generally between the health of men working in lead mines and the health of men working in copper or tin mines?—I am not aware that there is.

1227. Neither in your opinion is better or worse than the other?—No.

1228. What is the average of wages which an industrious man earns in a mine such as yours?—About 3*l.* 12*s.* 0*d.* per month in the 12 months is the average of our men's earnings in the mine; that is, the underground men.

1229. You have none but grown men in your mine?—We have two or three about 18; not less than 18; young men; they are then coming to manhood.

1230. Do you mean that the earnings of your men average 18*s.* a week?—Yes; at the mine to which I belong.

1231. Is not that an unusually high average?—I do not think that it is, for the eastern part of the county. I think the wages are rather better here than they are in the western part.

1232. To what do you attribute that?—It is owing, perhaps to the people being more plentiful there, and everything acting upon that basis. Where there is a large supply of course things are cheaper.

1233. Do you not think that in a perfectly well-ventilated mine like yours a man is able to work harder, and therefore to earn better wages?—I think so; the better the ventilation the better it is for the man and the employer.

1234. (*Chairman.*) With regard to climbing the ladders, do you think that a man may injure himself maferially by climbing the ladder too fast?—Yes, I think so.

1235. And therefore that the constantly having to climb ladders may affect his health?—Yes; it may, in the long run, of course. All constitutions are not alike, and with a weak constitution anything like extra labour or extraordinary exertions will tell upon it in course of time; there is no question of that.

1236. So that, independently of the ventilation, a man might suffer from climbing the ladder?—Yes; I could not say that a man could climb the shaft without feeling that he was climbing up hill.

1237. (*Mr. Kendall.*) Do you fancy that the ventilation of the mine at all affects the wages, one way or the other, in this district. I hold that your mine is perhaps one of the best ventilated mines in the county of Cornwall. Do you think that that has any effect upon the wages, either one way or the other?—I cannot tell, but we have always been able to allow our men the wages. It is a folly to have a mine, and to have men, unless you can pay them.

1238. Are the wages you pay higher than the wages in the district?—I cannot tell; I do not scrutinize the accounts; I cannot speak positively. I cannot speculate upon the other mines in the district, or upon the average wages.

1239. You never suffer from a want of men?—No; I am glad to employ them; I am sorry to find that the times are looking so bad among the mines. Miners are very scarce.

1240. You have not discharged any men, have you?—No.

1241. You keep up your number?—Yes. I should expect that about seven-tenths of those men that we have employed have worked there for eleven years.

1242. (*Mr. Austin Bruce.*) Have they been men employed at tutwork, or how have they been employed?—They have been all set.

1243. A man working in a good atmosphere and in a healthy state of body I presume would gain more than a man working in a bad atmosphere?—Of course he would.

1244. In a well-ventilated mine it would appear to you that a man must earn more than in a badly ventilated pit?—I think he can.

1245. (*Mr. Kendall.*) And he would earn more, would he not, for the adventurer?—Yes; it is better for the adventurer too.

1246. (*Mr. Holland.*) A man would earn in that case more for himself as well as for the adventurer?—Yes; and a man can work more cheerfully, and a man can work better.

1247. Does he receive more pay?—If he takes a bargain, and he has his tut, and if he exerts himself.

1248. (*Chairman.*) Does a man in taking a set generally consider whether the mine is well-ventilated or not?—I do not know; but it is his business to see whether he can take a bargain before he takes it and works it.

1249. But would he consider beforehand whether the mine was well ventilated or not?—I should suppose he would consider whether it was a good place or not.

1250. (*Mr. St. Aubyn.*) You stated before that you were not acquainted with the rate of wages in any one mine but your own in your own neighbourhood?—No.

1251. Do you know whether the wages are more or less than 3*l.* 12*s.* a month?—No.

1252. (*Mr. Kendall.*) I suppose that there are few men whom you meet with who consider more carefully what is for and against them than miners?—A miner understands the whole thing as well as his agent.

1253. You are obliged to have your wits about you to consider what operates against the men and what operates against you?—Yes; it is only fair that we should be the men who should behave justly to our labourers.

1254. But they are to a certain extent well able to take care of themselves?—Yes, they are quite competent for that.

1255. You think that they are sharp enough?—Yes.

1256. (*Chairman.*) What is the highest rate of wages any of your men earn?—The shaft men are what we call the first pair men, and they generally carry off about 4*l.* 5*s* or 4*l.* 6*s.* per month.

1257. What do the less skilful class receive?—Perhaps one pair that might leave now might be there again and not leave for six months.

1258. Does a bargain last for six months?—No; only for a month. We generally give the full extent at the setting day. The full extent is quite sufficient for the whole month, to give them a fair month's earnings.

1259. May they go on for another month at the some rate?—No.

1260. When you put the setting up, is it done by a sort of Dutch auction, that is to say, by bidding upwards?—We always measure the bargain, and fix our new process for the morrow.

1261. Is it set at the price you fix upon it?—Yes.

1262. If you offer it to a man who has been working, and he refuses it, is it then open to another to offer for it?—Yes.

1263. A man, I suppose, sometimes makes an offer, and they try to get more?—It has been so. I have seen that in the west, more than I have seen it here; but I do not remember any pair party cutting down any party in our mine at all. They do not seem inclined to do that kind of thing.

1264. Can you state to the Commissioners the lowest rate at which the men work for any set?—Perhaps a man might work a month for 50*s.*; he might do so; and sometimes as agents we advance a trifle to him, rather than send the man home; that is to say, we would rather lend him a few shillings, and when he does well take it back again. For example, a man with a large family. We do not like to be hard hearted to him.

1265. That is money to assist him?—Yes.

LISKEARD.
Mr. T. Trevelyan.
15 April 1862.

1266. That would be in a case, I suppose, where a man had made a bad bargain; for example, when the end has turned out harder to work than he expected? —Yes.

1267. So that sometimes a man in taking a set or bargain finds that he does not earn 50*s.* a month?—They might work for 1*l.*, probably. The bargain might turn out badly, and a man might not earn 1*l.*; it is possible.

1268. In that case would you advance the man money?—It is optional whether we will do so or not; we are not bound to do so; but some men are more humane than others; some men would, and some would not.

1269. Otherwise a man might not earn 1*l.* a month?—That is so.

1270. And that depending upon the nature of the ground?—Yes.

1271. (*Mr. Austin Bruce.*) How do you manage about your schools?—We have a school in our village close to the mine; it is a national school, and that is the only day school; our mine is close to the village.

1272. Have you found the miners anxious to send their children to school?—I believe that they do send them to the national school.

1273. At what age do they send them there, and how long do they keep them there?—Those who are more immediately connected with the mine, and who live in the village, perhaps send their children from the age of about five or six until they are eight or nine. Some of our men are scattered about, and are perhaps two miles off; but really I cannot answer the question perfectly.

1274. Do you mean that they take their children from school at the age of nine or ten?—Sometimes they remain at home, to assist at home, if they are little girls; but if they tre little boys they go perhaps with a farmer sometimes. They are not employed in the mine, for indeed we could not employ the whole of them.

1275. Have you any schools in which to teach the art of mining, and the art of ventilation?—No.

1276. You trust to an intelligent workman picking up experience in the mines?—Of course there are no better teachers than the men who have been working. We can always tell where the air is coming from, and find out which way we can send a current of air to the men when they are working; we find that out by experience.

1277. (*Chairman.*) You have used the words "send a current of air." How do you send a current of air?—If we found that the air was coming out of a certain level, and we wanted to put it in further, if there was any winze or hole that the air would go down, we would put in a door so as to prevent it, and send the current right on. We manage to get all the air that we can.

1278. You do put in doors?—Yes, sometimes, to prevent it going back again.

1279. You do not employ, I believe, any boys at the surface?—Yes; we employ several; we employ perhaps 20 boys.

1280. And women?—Only six little girls.

1281. Are the boys employed in picking?—In jigging and wheeling, and sundry other work, and many processes that we have in bringing the ore to a marketable state.

1282. Do they work under cover?—Most of them work under cover.

1283. What wages do those boys earn?—From 8*d.*, 9*d.*, 10*d.*, up to 1*s.*, and sometimes 1*s.* 3*d.*; just depending upon their size.

1284. What do the girls earn?—About 8*d.*, 9*d.*, or 10*d.*, which is the highest.

1285. (*Mr. Austin Bruce.*) Do you consider that you have an ample supply of men who are capable of conducting the ventilation of those mines?—Quite ample.

1286. (*Mr. Kendall.*) I suppose they find out in a second the state of the air by the burning of the candle?—They can find that out in a moment by the burning of the candle.

1287. And the moment that is observed you begin to consider how you can get the air to that place?—Yes.

1288. And do you seldom or ever fail to effect that object?—Never. We can always account for all those things.

1289. (*Chairman.*) Are you speaking now of your experience of other mines, or of your own mines where you have no difficulty?—The same remark applies to most mines that I have seen.

1290. That is, that there is no difficulty in supplying a sufficient quantity of air without resorting to artificial means?—Your are obliged sometimes to have recourse to artificial means at certain places with certain objects; but generally speaking we get sufficient air for the mines.

1291. (*Mr. Kendall.*) You worked in Dolcoath in the olden times when it was very deep?—Yes.

1292. What was your age then?—About 20.

1293. To what depth did you then go down?—200 fathoms. I worked down to 200 fathoms under the adit, which was above 40 fathoms from the surface.

1294. Do you recollect how far you went down in any end before you connected it by winzes?—As well as I recollect, that level was in from the shaft about 14 to 15 fathoms.

1295. Did you work there with artificial ventilation?—No; it was all natural ventilation.

1296. At 200 fathoms you were 14 fathoms off the shaft; there were no winzes, and you there had tolerably good air?—Yes; it was very warm, but the air was good.

1297. Did you ever burn more than one candle?—Yes; two men would have two candles.

1298. They were wanted for the purposes of giving light?—Yes.

1299. And none of them went out?—Not at all; there was very good air.

1300. (*Mr. Holland.*) Have you any means of telling when the air is bad, or when it is not so bad as to make the candle burn dim?—That is the first indication that we have.

1301. As long as the candle burns you consider that the air is good?—Of course it is good; but a man can live where a candle will not burn.

1302. You consider the air to be sufficiently good when a candle burns well?—Yes; that is the true indication.

1303. Any smaller degree of badness in the air than that passes unnoticed?—No.

1304. That is your test?—Yes; if we find the candle burn well they are satisfied.

1305. (*Chairman.*) And, on the other hand, when the candle does not burn well does the man report it?—Yes; at once. He would say that the air was bad, and he would complain to us immediately.

1306. How would that affect the work which he had contracted to do? Should you make any allowance to him?—We are as much interested to work out the bargain as he is; we have our returns to make, and we must do it for our proprietors' sake, and for our own; we should therefore go at once, and make an improvement where it was required. We are interested just as well as the man is.

1307. Then if a man were not able to work would there be a deduction made from his allowance for the set?—It is not our policy ever to keep him at a stand still. If he could not accomplish the amount of work that he ought to accomplish if he had good air, of course he would suffer a loss, and of course he has a strong motive to report that the air is bad.

1308. Still there is also a motive for him to get through the work?—Yes; but if the air is dead against him, or he has no air, he cannot carry a light.

1309. Although the air is bad, yet as he would not be earning anything if he were to stop work, he might persevere in working, although the air was bad?—Yes; that is the case, sometimes; and perhaps he per-

severes a little. We persevere sometimes, and by persevering we often do a thing, and consummate it as we would wish.

1310. But you cannot always do as you would wish ?—No; and the miner understands that; and when we are doing our best, if it is impossible to do anything more, he bows to that.

1311. And then he works on to the best of his ability in the bad air ?—Yes; if there was an object to be accomplished. Sometimes we want to communicate with another level, and we might be sinking and rising, and if a man thought then that he might soon accomplish perfect ventilation, he might persevere.

1312. Even at the risk of injuring his health ?—Yes, even at the risk of doing that; but perhaps he does not take that into consideration; that is, for a day or two.

1313. I thought you stated that it might take a month to accomplish it, and yet that a man would try to work in the bad air ?—Yes; and I do not deny that they sometimes do work in air that is not good for a month or two; the air may not be good.

1314. Do they ever work longer than that in the bad air ?—I cannot say but what they have in some cases; in some cases they might work in that way for three months.

1315. Have they ever, within your knowledge, worked as long as six months ?—They might, but I cannot tell; I cannot say that they do not sometimes, to accomplish an object. Sometimes we rise and sink, and the air might be bad; but we labour in order to perfectly ventilate the whole mine.

1316. But the men who work in bad air sacrifice their health to a certain extent, do they not ?—Of course they know that the air is bad; but there may be some little additional pay that they might like to labour to accomplish, and there may be in some cases an inducement held out.

1317. They would be induced by additional pay to work in bad air ?—If a man is working, and making a little sacrifice, he is worthy to be remunerated by a little extra pay.

1318. (*Mr. Kendall.*) Does it ever enter into the calculation of those who set the ground to give the men a little extra money to work in bad air, in order to save the expense of forcing in better air ?—I do not think it does; not if they could put in the air.

1319. But there are some cases, as I understand you, in which you think there is very imperfect ventilation; for instance, before they can get their communication, and where they cannot have the means of forcing in the air, and in those cases the men work for some hours to the detriment of their own health ?—I think that that has been so many times, even after air has been brought in artificially, but not in sufficient quantity; notwithstanding everything that has been done, the men will persevere for a month or two, and I believe the men have been rather more remunerated for that place.

1320. (*Chairman.*) You are of opinion, I suppose, that you ought to use all the artificial means that you can to introduce fresh air ?—Of course; and I believe that that is usually done.

1321. (*Mr. Kendall.*) Do you think that the persons who are engaged in mines are more careful of the miner's health, with regard to ventilation, than they used to be ?—Yes, in every sense.

1322. The men, I suppose, are more sensible, and understand the necessity for it, and the adventurers also fully appreciate the importance of it ?—Yes.

1323. Still, do you think there is room for improvement ?—I cannot say that, for I believe that as much is done as can be done; and it is for the interest of the proprietors, the masters, and agents themselves. Any agent must know, that if he can ventilate his mine he will get it into good working order, and then it is best for them all.

1324. You do not know of any artificial means being used from the surface to force down the air; they use nothing but fans ?—No; I do not know of any place where it is artificially thrown down from the surface. They have fans at certain places which I have seen, until a communication has been made.

1325. Until that communication is made, it is only by fans at the nearest openings or winzes ?—Just so.

The witness withdrew.

Mr. JAMES SECCOMBE examined.

Mr. J. Seccombe.

1326. (*Chairman.*) I believe you have charge of two mines ?—Yes.

1327. East Caradon is one ?—Yes.

1328. And Marke Valley another ?—Yes; and there is a new mine adjoining; West Rose Down.

1329. Then there are three mines ?—Yes.

1330. Of which of them have you brought a plan ?—Of East Caradon and Marke Valley; the other is a young mine.

1331. What is the deepest level of East Caradon ?—Seventy fathoms; that is, below the adit; so that it might be called 90 fathoms from the surface.

1332. How many men are employed ?—We have had about 80 men under ground.

1333. And how many above ground, including women and all ?—Including girls and boys, we may have 50.

1334. Have you any boys employed underground ?—I cannot say that we have what we call boys; we may have just two or three hardy lads, from the age of 17 to 18, that work with their people; working in the place of men.

1335. Any others ?—No.

1336. How do they reach the surface; is it by ladders ?—Yes.

1337. When they come to the surface to the change-house, is it the boiler-house that is used, or is there a separate change-house ?—At present we are changing at the boiler-house at East Caradon.

1338. Is that boiler-house far from the footway ?—We have a boiler-house now, at, it may be, 20 or 30 fathoms; what used to be our principal shaft before the operations of the mine increased; then our boiler-house was almost close to the shaft.

1139. Are you sinking another shaft ?—Yes; we are sinking one now, or trying to get a communication through, as I may term it, entirely for ventilation and better accommodation for the footway.

1340. Are you working at both ends of that shaft, both from above and below, or are you driving the shaft merely from the surface ?—It is the upper shaft now; we are bringing forth the shaft now; our level is from the midway level between 50 and 35.

1341. Where the men are working down below, is the air good where they are working ?—It is not so good as we could wish, and not so good as I expect it will be when we get this second shaft. Now we have winzes; but that is not like coming down from the surface.

1342. How long have you been working at this shaft ?—We have been now, I suppose, the greater part of 12 months about this shaft, and we have got from the surface down to eight or nine fathoms below the 20 fathom level; perhaps from 40 to 50 fathoms from the surface.

1343. How long have you been working up ?—We have not began that yet; it will take us this month to get in on to the top of the place to begin to rise.

1344. How long do you think it will take you to rise up ?—Perhaps three months.

1345. During that time the air, I presume, cannot be good ?—During that time we are not so well ventilated as we shall be afterwards. I do not know that the men complain of want of air. I know that

LISKEARD.

Mr. J. Seccombe.

15 April 1862.

when we get a second shaft our smoke and dust and things of that sort have gone off much faster.

1346. Is it dry working up?—It is dry pretty nearly where the men are working.

1347. Is there any dust created by the working?—In a dry place you will generally have a little dust come.

1348. Do the men now ascend by ladders?—Yes.

1349. Are you driving the new shaft with the view of making another footway?—Yes.

1350. Are the men also to ascend by ladders?—Yes; we are not deep enough for anything else yet. We can put our ladders in a very slanting direction, and so make it easy for our men to climb up.

1351. Are they at the present time perpendicular?—No; but they are pretty nearly so.

1352. Do the men, when they come to the surface, appear exhausted by their exertion?—Yes, sometimes, if they hurry up.

1353. Sometimes they race up, do they not?—Sometimes it does happen that they come up very fast; but that will occur more among the young men and the boys. The older men have had more experience, and they take it more steadily.

1354. The men are fined, are they not, if they come up before the time?—If they are up pretty much before the time.

1355. Do they ever wait in the shaft before they come up?—Sometimes they come, and sit down in the plat, where there is a dry place.

1356. Why have those men left their work before the time?—We find that men in the beginning of the month do so sometimes; they do not do it so much towards the latter end of the month; they take things then very steadily, when it comes to the latter end of the time. When the month is just up they work harder sometimes, and we find the men are inclined to stay down an hour or two longer than the time. Some are very indifferent towards the time when they ought to come to the surface.

1357. Have they any means of judging of the time, except by the candles?—They can tell very nearly by the candles; but some of them carry down a watch too.

1358. In the other mine, the Marke Valley, what is the depth there, is it deeper than the one we have been speaking of?—The deepest level is 100 fathoms below the adit; that is nearly 130 from the surface.

1359. How many shafts are there there?—We have got three or four shafts in the mine; but with this fresh part we should have three shafts connected as deep as 80 fathoms from the surface; but the two principal shafts now are both within five or six fathoms of the depth of each other, but the level is not communicated below 80.

1360. In the deepest part of that mine there is only one shaft at present in connexion with it?—No; I might say below the 110 fathoms, so that there would be nearly 20 fathoms; one shaft is nearly 20 fathoms deeper than the other; but there is a level driven at the 90, which has many winzes through from the one to the other, causing a thorough draught all through.

1361. At the bottom, where the men are working, is it hot?—It might be termed warm, or rather hot, in our 100 one pair, but not in any other pair; that is what we call the sumpt pair.

1362. Are there any special means used for ventilation there?—No more than we have already done. We intend it, as soon as we cross-cut the lode. We shall get on where we have a winze from 80 to 90. It is intended to do it.

1363. But in the meantime, and until you accomplish that, are there any special means employed for ventilation?—They will have the water fall from the 80 down to the 90 perpendicularly, and that throws the water through some pipes, to keep this level cool and fresh; that is the 100, and that will be required before the winze is communicated from the 90 to the 100.

1364. Then that is artificially ventilated by means of water?—Yes.

1365. It is perfectly ventilated?—Yes.

1366. Is there any place in either of those two mines where candles will not burn?—Not now, that I know of. We have one level that we have suspended for 12 months, our 80 west. That is done on account of a change of weather at the surface; not otherwise; and that we suspend before we get other levels up.

1367. You suspended the working in that level on account of the air not being good?—Yes, 12 months ago, because when there are uncertain winds and not clear weather at the surface there would be an occasional change when the candles would not burn so well, and we have suspended it, before we get other levels up to drive the air on by winzes.

1368. The natural ventilation of the shaft is affected by the weather?—Only on rare occasions. I am not aware that I know of it in any other place besides that.

1369. How far was the end from the shaft when you stopped the working?—I should think perhaps 70 or 80 fathoms; not quite so much as that, perhaps; say about 63 fathoms.

1370. While the men were working there, and before you ceased working, were they entirely without ventilation?—Yes, they were.

1371. Therefore it was not for their advantage to go on working then?—No; it was not so well for the men. I think that the better air you can get for the miners, the more labour they can perform; and, in fact, it is more healthy too, when the place is well ventilated.

1372. In driving your levels, what is the height and what is the breadth?—We set our levels to be carried seven feet high; we may be as narrow as four feet and a half or five feet; we generally set six feet; but I have no level that I have set less than five feet wide.

1373. But I presume it is worth your while, in order to work profitably, to have a good width and height?—I should say that it was generally profitable.

1374. Does that add very much to the expense?—I do not think it does. There are certain instances where a level would be very fair, although narrow; but where there is a level to be carried, I would say have them of a good breadth for tribute working, sometimes they are worked more narrow. I think that four feet and a half is narrow enough.

1375. In working there, are the deads immediately conveyed away, or left in the level?—Sometimes we have particular sorts of work at the plats.

1376. In your opinion, does the leaving of the deads impede the ventilation?—Yes, if they are left very long; but we manage to get them out as often as can be.

1377. Have you ever divided a level for the purpose of ventilation?—No.

1378. Have you ever tried the effect of dividing a level, for the purpose of forming a current?—No; we put in iron or wooden pipes, or zinc pipes, to throw the air in, and then turn the draught by placing a trap-door across the level, and so not to let the air escape before it goes into this run of pipes; there is just room enough for the mouth of the pipe underneath.

1379. You use these pipes for the purpose of conveying air?—Yes, if they are wanted.

1380. Did you say that they were of zinc?—They are sometimes of zinc, sometimes of iron, and sometimes of wood.

1381. Iron pipes would be expensive, would they not?—I have used 100 fathoms in Marke Valley, for after putting in zinc I found that where the water came it soon knocked holes into the pipes, and I found that the iron pipes were cheaper.

1382. At present, in Marke Valley, part of the ventilation is carried on by wooden pipes?—Yes; but the principal part of our works does not require any but the ventilation from the shafts and winzes from level to level.

1383. It is only while you are driving an end that you want those pipes ?—Yes ; but as soon as we get the winze through to the next level, that will do away with the necessity for them.

1384. What is the difference in the cost between iron and zinc pipes ?—Perhaps six or seven shillings a-fathom.

1385. And what is the price of the wooden pipes ?—They would be cheaper than either of the others.

1386. Would not wooden pipes answer as well as zinc pipes ?—I do not think wooden pipes would do ; I think that they deaden the air a little sometimes, for a long distance.

1387. Will you be good enough to state how you take up the ore ?—By kibbles.

1388. There is another mode, is there not ; by skips ?—Yes. We do not use them at present, but it is not unlikely that we shall use them in course of time.

1389. The skip is closed, is it not ?—Yes.

1390. Is that the more profitable mode of working ?—When we have got the skips and the guides in, the ore is drawn through the shaft best.

1391. Is there any danger in the use of kibbles from the stuff falling out ?—If they are drawing very fast, they might hitch one into the other ; but the men generally manage to have the winze stopped when they are passing through the shaft, otherwise it would be attended with danger, and stones might, by chance, get into the other shaft.

1392. Have you ever known such a thing as that occur ?—I have known stones come in.

1393. Therefore the skip would appear to be the safest ?—The skip is rather the safest. While the chain and everything is all correct, there is not the same liability to hitch or entangle as the kibbles would.

1394. How many men have you working in the Marke Valley Mine ?—About 120.

1395. Do they all work under ground ?—Yes.

1396. Are they both tribute-men and tut-men ?—We have no tributors underground ; they are all tut-men.

1397. Are both the mines copper mines ?—Yes.

1398. You have no tribute-men underground ?—No; not underground.

1939. How is the ore set to the tut-men ?—At so much per fathom, for six feet long and six feet high ; thirty-six feet.

1400. Do you consider that that is a better way of working than by tribute ?—In places I do ; but it depends upon the nature of the lodes. If they were very small lodes and bunchy, then perhaps tribute might be of the greatest advantage.

1401. Where there is a good lode, which should you say was the better plan ?—Then I should prefer stoping ; but there are exceptions; many agents do not say so.

1402. It would be necessary, I suppose, that the agents should be thoroughly conversant with the value of the lode ?—Yes.

1403. And also as to the amount of work that they ought to turn out ?—Yes ; the tributors would require that.

1404. Under the system of tribute, I understand that the man is a part speculator in the work ?—Yes, he may be called so; but you do not get many men to work until they see a lode that will turn them out so many tons to a fathom.

1405. But it varies very much ; sometimes a man may make a good speculation, and sometimes a bad one ?—Yes; sometimes a bad one.

1406. With regard to tut-work, the pay is less fluctuating, is it not ?—Yes; they have not got to calculate so much, but I think if there were different modes in the setting of tribute we should get more men that would know well enough about tribute, only that the tribute pay is not so quick as the tut-work pay, but my late brother and another person whom I knew considered it a very good plan that they should give the tributor a fixed standard, and then they could pay him as quick as they could at tut-work bargain, for when they got a sample they would know then the quantity likely to be produced, and what portion they must pay him for his produce.

1407. And that system you think would be better for the men ?—Yes. I think that they should not have the standard to speculate with at all, but only the quality of the lode, and the easiness or hardness of the ground, and so they would know how quick a certain piece of ground could be worked out; but that must depend upon the country.

1408. And upon the agent?—Yes ; the captain and the men.

1409. In many cases the tribute men, I believe, are often without pay for some time ?—Yes ; and they are allowed subsist, perhaps a couple of pounds, just to provide them with a little living before the balance comes. Sometimes they are working for five or six months before they settle up, and a great many of them do not like that.

1410. What wages can your men earn by tut-work ?—That depends somewhat upon the power of the men, and their judgment ; some would not earn perhaps more than 3*l.*, while others would earn about 3*l.* 10*s.* or 4*l.*; and we find rather more difference than that in some.

1411. What is the lowest that they would earn ?—Sometimes we might find them not get more than 2*l.*, while others might get 5*l.*

1412. I suppose that depends, not upon the men individually, but upon the pair ?—Yes; it depends upon the pair altogether.

1413. What do you allow them to get ?—Perhaps 3*l.* 10*s.*, the better men ; the shaft men about 4*l.*

1414. That is for sinking down a shaft ?—Yes, or driving our bottom level ; they have a little more trouble than others with the water.

1415. And therefore they earn more money, which they draw ?—Yes; they are worth about 10*s.* a month more.

1416. Is it the result of your experience that the men prefer shaft work to working in the ends ?—I cannot tell you ; I do not think so. I myself have been brought up in that way as a boy from about eleven years of age. I worked underground until I was grown a man some years afterwards. Some young men think that they gain a certain advantage, or that they are superior men to others,when they get to work in a shaft; others prefer a dry place, and never go into the shaft at all to work.

1417. As you have worked so long underground, have you ever suffered any ill-health from working underground ?—I have worked in places where I find it very bad for that when I was a boy.

1418. You suffered from want of ventilation ?—Yes.

1419. Have you known of other cases in which men have suffered in their health materially from the same cause ?—I think that there has been a great improvement in latter years to what there was when I began at first. We did not think then of carrying down a mouthful of any thing to eat with us, even if we stopped down for 10 or 12 hours, nor to drink; and sometimes, when there were two in a pair or four in a pair, they stayed down longer, but now we find that almost all the men carry down with them a little water to drink, and a bit of something to eat.

1420. What do they carry the water down in ?—Sometimes they have a little keg tied round their waist, and sometimes they carry a bottle.

1421. I suppose that in a hot end the water becomes very warm ?—Yes ; and the men perspire a good deal in working, but I think the water is a benefit to them, and that they are better calculated than what they used to be to take care of themselves.

1422. What should you call a hot end; at what temperature ?—From 60 degrees to 70 degrees would be pretty hot with them, but not so hot as they get it in the western part of the county. I have never been down more than 200 fathoms deep.

1423. In the course of your experience during the last few years, have you found that any of the men have been obliged to leave their work underground,

LISKEARD.

Mr. J. Scoombe.

15 April 1862.

and take to surface work, on account of having contracted some disease?—I do not know that we have had many men that have suffered injuries; they have laid by some of them but not entirely I think from the bad air; I do not know it. On recollection, I remember that we had a man of the name of Lawrie, who worked with us, but he was becoming an old man, and we did not know what mine he had been injured in. I think that ours was his last place of work. He was asthmatical.

1424. Do you think the men do suffer who have been working underground?—Yes, if they work in close places, which are not well ventilated, they must.

1425. Do you think it more frequently happens that they do work in close places in young mines or in old mines?—It depends upon whether they are very far off the draughts.

1426. Suppose the case of a new mine, where they are driving to reach a shaft?—Sometimes, in young mines, we only get one shaft to go through the lode, and I do not think that that is hardly at the same depth as if there was a second shaft down. I think that when a work becomes more extensive, and will warrant it, a second shaft should be got down for ventilation.

1427. Until that work was finished, would there be any artificial means of supplying air?—If it were very bad, we might throw it down from the surface, and that is done pretty generally so.

1428. Have you ever seen any means resorted to for throwing down air from the surface?—At the adit level we might turn down a stream of water; and this shaft that I spoke of here that we sunk is so far without ventilation that on times we found inconvenience from the air, and I got a run of iron pipes put in nearly all the way, and just as that was done the air was considered good enough.

1429. By what means do you ascertain whether the air is good enough?—I cannot tell you; but in summer time it is affected.

1430. But how do you judge of the state of the air?—We can judge well enough only by the burning of the candle. If we get into a close place the candle does not burn so freely.

1431. Does the miner then give notice?—He says that he has a trouble to keep his candle alight; that the air is bad; and he is then perhaps removed.

1432. I suppose there are cases when you are anxious to form a connection in which the men persevere in working and in bad air?—That might happen at times, if the air was not very good, nearly upon the point of holing, and they would try to get through it all.

1233. Do you pay the men higher wages under those circumstances?—I do not know that we have.

1434. I suppose that if the men do not complete their bargain they must work on in bad air, or they would lose?—That I cannot tell you; not particularly; they are not bound to work if the air is bad.

1435. They would not forfeit what they had already done?—No.

1436. So that when a miner finds that he is breathing bad air he can report it to the captain, and then he would not lose?—One of the agents of the mine would go and see for himself, because if the ground had got harder since the man had taken his bargain he would be glad to get that for his excuse, and not work.

1437. If he found that he had made a bad bargain he would be apt to ascribe it to the effect of the air?—Yes.

1438. How would you test the condition of the air?—We should go and examine it for ourselves by our own candle, and see how we could breathe in it; and if the candle burnt very well, I have never known any danger occur.

1439. But suppose the candle did not burn very well?—Then we should think that there was something amiss.

1440. Have you any other mode of testing the state of the air?—No.

1441. Suppose that the candle burnt feebly?—Then we should say that the air was not very good.

1442. Would a man, under such circumstances, be relieved from his bargain?—That would depend upon whether we thought it was sufficient to injure him or not.

1443. Do you find that by changing the position of the candle in a level it makes a difference in the burning of the candle?—I have known instances where, just on cutting a hollow place, immediately the candle would not burn against it when it would burn anywhere else; that is perhaps for a few hours.

1444. When you pay the men (the pairs) do you pay them the full sum in notes?—If they are a pair together, like eight or nine men, we might pay them nearly half the money in notes, the remainder, or nearly all the remainder, in sovereigns, and some silver generally goes out. Then, if we have got three or four or five or six of the surface men, if they have got to receive 2*l.* or 3*l.*, or 3*l.* 10*s.*, we should manage in this way: the pit pairs would take so many sovereigns, so many half sovereigns, and the remainder in silver; and as I know exactly what I want when I am going into the bank, I take so many notes and so many sovereigns down. With regard to the other pairs, everybody that has got to receive so much, say a sovereign, will be paid in sovereigns, and every one that has got to receive half a sovereign will have it, and everybody below that sum will have to take change.

1445. If the men wanted change for their notes would you give them change?—If they were to say we would like to be paid in sovereigns altogether, or in notes, we should do it for them.

1446. But suppose they did not get the change from you, how would they change their notes?—They generally go to have something to drink upon the settling day, if there is no money to be received at all on the pay day.

1447. Do they obtain change for their notes at the public house?—Yes; they go and pay what they have on the settling day as well as anything else.

1448. Is it general among them on the settling day to go to the public house?—That is where most of them go, after taking their month's bargain, to have a little beer.

1449. Generally speaking, the settling is in the morning, is it not?—No; it is generally about one or two o'clock.

1450. Do the men work after that?—No.

1451. (*Mr. Kendall.*) What age are you?—About fifty-four.

1452. You have been talking about being asthmatical; do you think that was caused by working in your early days underground?—I can hardly say that. I recollect that Mr. Pierce, the surgeon, used to attend us when I was about 17 or 18 years of age, and he told me not to work in the place that I did, on account of the bad air; but I always had a cough as a young man.

1453. Before you went mining?—I went mining when I was about 11 years of age.

1454. But had you a cough before you went underground to work?—I cannot recollect that.

1455. Does the asthma affect you in ascending or descending?—Yes, in ascending, but not in descending.

1456. Do you go underground now?—Very little; not within the last six or eight months.

1457. How many agents have you under you?—Five agents.

1458. Your brother was a man of great experience, and he died early; how much older was he than you are?—I am older than he was, about two years and a quarter.

1459. How long has he been dead?—Three or four years.

1460. Was he your only brother?—Yes; he took influenza.

1461. Was he constitutionally delicate, like you?—No; he had no cough at all.

1462. From what complaint did he die?—I cannot tell.

1463. Was it from over-working in the mines?—He worked very hard; but I think not the mines altogether; he had a pretty good many speculations.

1464. And he exerted himself very much, did he not?—Yes. I have been accustomed to do that myself for some years. I go down two mines in a day now very often.

1465. What depth have you been down into these two mines?—150 fathoms.

1466. You come up, I suppose, very warm?—Yes.

1467. Then you would change your clothes, and ride across a cold country, and then go down another mine, and then you wonder that you are ill?—Yes.

1468. Is it not true that you are, as a body, very careless about these matters, especially when young?—Yes. I went to work underground at about 11 years of age, and I worked hard to do my task by such a time, and I used to get up, and climb, and try to see if I could not get up as fast as others; but I know now that it is very wrong.

1469. I suppose you had some object in view?—Yes; it was to try to see how quick I could get to the surface.

1470. In your opinion, are the miners now-a-days more careless or more careful than they used to be?—They are more careful. There are many hardships that we used to have to go through in those days that we do not have to bear now. For instance, we very seldom see a wheelbarrow now; the stuff is all taken out by tram waggons. I have wheeled many a time when my fingers have been ready to go right out, when I was not able to hold anything, and the weight was supported by a sling round my neck; that was before they introduced the tramway underground.

1471. With regard to the drys; have you got a dry at Caradon?—No. We have got new engine houses there. I wanted to erect another before I got a dry there. We have ordered a new engine, and we are going to try wrought-iron beams. Mr. West, the engineer, has taken the contract.

1472. What is the advantage of the wrought-iron beam?—The object is to prevent any breakage.

1473. Do you intend to have a dry?—Yes.

1474. Is your mine a wet mine?—No; I cannot say that it is. The men have almost all dry places to work in.

1475. What do the men do with their clothes?—They hang them up all round the fire doors.

1476. You are of opinion that you ought to have a dry there?—Yes; and it is very likely that we shall have one as we get further on. I may say that we intend to have a dry.

1477. Ought you not to have a dry?—I think that our men now can change very comfortably, and we have never had an accident, although we cannot say that the thing might not occur, and therefore it is thought to have a dry. We have a stack put off a certain distance from the boiler-house, to put a dry there. In going down through this mine I have to consider whether we shall have a place between the boiler-house and the stack for the sake of a dry.

1478. What does a good dry cost?—Not much.

1479. About how much?—Not above 100*l.* for a mine of the size of ours.

1480. What would it cost to keep it at work?—Perhaps not 10*l.* a month.

1481. I suppose there is no harm in saying that you could afford that?—We can, at East Caradon.

1482. That is the best mine in the country, is it not?—I think so. There is one thing, and that is that we have many things to do at the same time, and we cannot go and find masons enough to do as much as we like. I have great difficulty in that. I have just completed an engine-house, a carpenter's shop, and a smith's shop.

1483. With regard to dust, is it not a fact that the miners are injured by the dust that comes from the ore in working it? Have you worked by tribute a good deal?—Yes.

1484. And at tut-work?—Yes.

1485. You have had great experience, such as few men, compared with yourself, have had?—Yes.

1486. Did you ever see an instance, or more than one, of the dust coming from the lode, in the working, so as to be injurious to the men?—I would not say that the dust might not be injurious.

1487. There is dust, is there not?—Yes, where you work upon a very mundicky lode.

1488. Where you are working upon a mundicky lode there is a very strong smell, is there not?—Yes; upon the punching of the hole there would be a strong smell; but that might be prevented by keeping a mop around the borer; that would keep away the dust, and deaden it.

1489. Have you seen instances where the men have been negligent, and where there has been a good deal of dust from the ore which would be injurious to them?—I do not know whether there would be much from the copper ore; the mundic smells very much, if it is left to dry, and the dust is not damped.

1490. Where there is a good deal of mundic you think that a good deal of dust is caused?—I do not know that there would be more dust, but there would be more smell with it.

1491. But I am speaking of dust?—I think that, generally speaking, the men can prevent the dust from being injurious; they might at times throw a little water upon it, if they get into a very dusty place. Upon punching a hole with the bore at the commencement, and making an impression, the dust flies about, and if they kept a damp mop round it it could not come.

1492. Have you seen instances in which the dust does fly about?—Yes but with care the people might prevent it.

1493. The dust is of such a kind that a person would inhale it by breathing it?—Yes.

1494. Unless you took care, you would inhale that dust?—Yes, some of it, there is no question about it.

1495. (*Mr. Holland*) Does it sometimes colour the expectoration?—Yes; it is apt to do that, sometimes, but I think that the smoke from the candles has just as much to do with that.

1496. Is the dust from the mundic ever in sufficient quantity to colour the expectoration?—I do not know whether it has done it, but I should think that the smoke from the candle does it.

1497. And not the other?—I do not know that it does; but the smoke from the candle will find its way into the throat, and colour the expectoration.

1498. And the powder smoke?—Yes.

1499. Is that frequently in large quantities?—Sometimes we have a great deal of smoke; but the more we can get the mine ventilated the better. In some places, make what blast we would, in a few minutes the place would be pretty clear to go into, but not in other places. If not ventilated, the smoke would lie here, and remain there a long time, and the men would be working in it.

1500. Do the men often go back too soon after firing a shot?—Sometimes they do; sometimes they are very anxious to know what they have done, and they would run forward to see, and come back almost directly, just to see, and then come back and stop. They need not do that; but then they are very anxious to know.

1501. How long is it common for the powder smoke to hang about?—That depends entirely upon the draughts. Sometimes it might remain there for an hour, and at other times it would not remain for five minutes.

1502. What is the ordinary time?—Perhaps five or ten minutes.

1503. Is half an hour an uncommon period?—I should say that it was very uncommon; that is, where a draught is pretty close; that is, to be injurious. Of course they might see a little of it.

1504. (*Mr. Kendall.*) Did you ever know the men

LISKEARD.

Mr. J. Seccombe.

15 April 1862.

go in, and beat the smoke out of their jackets ?—Yes; I have known that to be done.

1505. Have you ever done that yourself ?—I cannot say that I have.

1506. Can you say that you have not done it ?—No. But there is a great deal of difference in men. I recollect, when I was lad of 18 or 19, working up in a rise, and I was down one day with a man who was nearly 60 years of age, and he went up in it; but it appeared to take no effect upon him, while I could not live in the place, it would so bring my cough on.

1507. (*Mr. Holland.*) I think you stated that the miners were less unhealthy than they were some years ago ?—Yes. I think that they take a great deal more care now in the underground operations. For example, in carrying water down with them ; if any dust gets into their throats it is likely to wash it down ; and they do not remain in so long with an empty stomach.

1508. And are they more careful with regard to the powder smoke ?—I do not know; but I think most men can stand it better than I can.

1509. Are the men more careful in avoiding the poor air than they used to be ?—I do not think they are ; but I do not know that there are such bad air places as there used to be thirty or forty years ago.

1510. (*Mr. Kendall.*) In East Caradon, have you got bad ends, which sometimes contain poor air ?—I do not know that we have any that may be called very bad. Our fifty might be taken to be rather close, but not injurious.

1511. Does the candle burn well there ?—I cannot say that it does.

1512. Have you taken any means of forcing any air into it ?—We have got a winze through from thirty-five down to fifty, and then we manage to carry the draught back over the stopes to bring it as near, in order to play round the end, as we can, and then we have winzes from there to sixty.

1513 How far is the fifty end from the winze ?—I cannot tell you how far it is from the winze; it is brought on by the stopes ; I think we must be thirty or thirty-five fathoms, perhaps ; I think we have got that ground on the stope. I think that is the worst end. We carry it round the draught as well as we can.

1514. (*Mr. Holland.*) Caradon is a young mine, is it not ?—Yes ; East Caradon is.

1515. From whence did the miners come; from the west ?—A great many of them came from the west ; some of them came from the easternmost part of the county, and all round.

1516. Many of the men may have contracted disease before they came to work in your mine ?—Yes ; many of the men have been miners before; the older men, and we cannot say where they have worked.

1517. (*Chairman.*) Are there any men, to your knowledge, now working underground, who are suffering from difficulty in breathing ?—I do not know that there are.

1518. When you engage a new miner, do you enquire into the state of his health ?—Not as to the breath ; but recently, or within the last few years, I have not liked to employ a man who has been blind of one eye. There is one working on the surface. I would not let the man go to work down underground again ; that was the first that gave me notice of his eye. He had received a blow in it; and I thought that that sort of man ought not to go down underground to work again, for if anything happened to the other eye he would be dark altogether.

1519. Had this man lost his eye in your mine ?—Not in ours. He had lost his eye in some mine or other.

1520. How does a man lose his eyesight in a mine ?—Sometimes, when he is breaking up the rock, a bit of stuff might fly into his eye, or a piece of steel or iron ; and if a man should have his two eyes injured it would be very hard to have them both affected at once.

1521. Have there been any accidents from blasting ?—Yes ; there is one man that we have been paying to, I should think, for ten or a dozen years. He is a young man, and he receives one shilling a-day from the fund. It is called the fund ; but I do not call it their fund at all, because every man, when he comes to know the charge, will look to the balance he has to take up. He sees what is to be deducted. It is nothing but a form. There is the doctor and the club, and it is deducted, and he sees the balance The men always look to the money that they have to carry away from the mine.

1522. But there are other deductions, are there not; for example, for candles and powder?—Yes ; for sharpening tools, and short weight. Those are deductions, and when the bargain is measured, his ground is made up to see what charge is made, and all those deductions come in.

1523. A man knows, of course, the amount he will have to pay for candles ?—Yes ; he pays so much a pound for candles, and so much for safety-fuzes, paper, and glass.

1524. Do you contract for the candles ?—Yes; with the merchant.

1525. Are the candles generally good, do you think ?—Yes. But if we find that they are of bad quality we do not give an order for them to the same merchant.

1526. Is it a common complaint on the part of the miners that the candles are bad ?—If we had bad smelling grease, and soft candles that did not last, the men would complain directly.

1527. Then you ascertain from the men the quality of the candles ?—They might pass without our noticing them, if a new cargo came in ; but as soon as the men came to use them they would find it out if they were bad, and come and inform us.

1528. Have the men complained of the smell of the candles ?—Yes ; and if they have we have always tried to remedy it ; but I do not know that that has occurred, I will not say that it has not, for years, about the smell of the candles.

1529. Have you ever known the men use their jackets in order to promote circulation in the air ?—I have known them take off their jackets, and I have done it for myself, and have come in. I wanted to see a certain end, and I could not see it very well.

1530. I meant to promote ventilation on account of the heat, and for the purpose of cooling themselves ?—No, I do not know that.

1531. Do the women on the surface work under cover ?—I believe that ours are very nearly all under cover. We have, perhaps, half a dozen pairs at East Caradon, that are not quite provided yet ; but as to all our women employed in cobbing, bucking, and rolling, we have sheds to contain the whole.

1532. Is any room provided for them to get their dinner or tea in ?—We have no room for that, on purpose.

1533. But is it not desirable that there should be such accommodation provided ?—I cannot tell you.

1534. It is provided, is it not, in some mines ?—It may be ; but whether they have far to go I do not know. The women send in their tea-kettles and get them boiled, and they get some cups.

1535. (*Mr. Austin Bruce*). You have worked in many mines, have you not ?—Yes ; I have been in a good many.

1536. Have you observed much difference between them ?—There is a difference, certainly.

1537. I mean with regard to ventilation ?—I believe the air is generally carried on upon the principle of getting winzes for communication as quickly as they can.

1538. Have you found much difference, as to the effectiveness of the ventilation, between one and another mine ?—I do not know of any that I recollect just for the present that is not carried out on as good a plan as it can be, in getting winzes through, or by throwing in air by a machine.

1539. You have stated that the men take more care of themselves than they did formerly ?—I think they do. They now have something to drink and to

eat during their work, and that I think, myself, is a good plan. My experience shows me that that is better for the men than to go for eight or nine or ten hours without anything.

1540. Do you think that the men are now enabled to continue at their labour a greater number of years than they were formerly ?—I cannot tell you.

1541. If taking greater care of themselves is an advantage to them, I suppose that will contribute to their health, and enable them to work for a longer period of their lives ?—Yes; that is, if they take all the other care of themselves that they possibly can.

1542. Have you ever been in collieries ?—No.

1543. Do many of the Cornish people go over to the Welsh collieries ?—I believe some of them do.

1544. Do you happen to know any of them ?—I am not aware that I do know any of them who are there now.

1545. Have you seen men who have been over there, and worked in the Welsh collieries, and have then returned ?—I do not know that I can recollect any.

1546. How far are your men mostly from their houses ?—Some might be a quarter of a mile off, others half a mile.

1547. Are any of them as far off as two or three or four miles ?—I think you will find very few of them who are as much as three miles away. Perhaps there might be a certain man or two who would go the fourth mile; but you would find now, in Liskeard, many men who like a town, and who, when they come home, and have a leisure time, like to have some place to go to and sit down, and have a pint of beer and smoke their pipe. Those men would sooner travel three miles to their work than go into a country place and live within half a mile of their work. But some men like to be as near to their work as they can; and sometimes in the country they have a good garden.

1548. You set no men to labour underground under 17 years of age ?—Yes; some as early, I should think, as eight or nine; but then they would be employed to pick up little stones.

1550. What wages do they receive ?—I think the wages for what they call tributory advance might come down as low as fourpence a-day; but it is a very rare occurrence to find one so low as that; it varies from sixpence to sevenpence and eightpence, and on to a 1*s*. That would be for women and girls.

1551. I think you stated that you had about 80 men working below ground ?—Yes; at East Caradon.

1552. How many of those 80 would be above 40 years of age ?—I should think several of them.

1553. Have you got any return of their ages ?—No.

1554. Have you known of any instances of men working after the age of 60 ?—I believe I have; but it is rather a rare occurrence.

1555. Are there any men working underground in your mine above the age of 60 ?—I do not think that we have any underground who are so old as 60; but I cannot tell with certainty, for I do not know.

1556. Are they generally a temperate race of men? —Some of them are very temperate and industrious; but some of them, on the other hand, are just the other way; the young men particularly; you will find that they are not so temperate as you could wish them to be.

1557. Are their houses pretty neat and comfortable ?—I cannot tell you; but I should not think that they were so comfortable as they would like to have them. Men marry and get their families at an early age, and then they find that they have something to do to get comfortable houses. Sometimes it happens that a man has three or four children before he gets any of them to go to work. I remember very well the saying of an old man that I knew, which was this—"that after a man has got half-a-dozen children, it does not matter how many more he gets, as some of them will go out to get their own living."

1558. Is fuel dear with you ?—I cannot tell you much about that; perhaps they may have to give 1*s*. a cwt.

1559. About 1*l*. a ton ?—Yes, and sometimes a little more, may be 1*s*. 1*d*. or 1*s*. 2*d*.

1560. You stated, a short time ago, that you were going to put in an engine with wrought-iron beams; have you found any of the cast-iron beams break ?—Yes; we had one break at Mark Valley; one side of it; not the whole of the beam.

1561. Did any accident happen in consequence ?—No.

1562. Have you heard of any other instances of the kind ?—None have come under my notice. But I must be excused when I say that, for I am speaking of the Cornish mines and the Devonshire mines. I have heard a great deal about the Hartley Colliery misfortune.

1563. You wish to avoid the breaking of the chains ? —Yes.

1564. I suppose that where the miners have large families they are apt to take lodgers into their houses ?—I cannot tell you much about that; but I think I have heard that it has been done.

1565. (*Mr. Holland.*) What number of bed-rooms have they in their houses ?—Some of them, I believe, have not more than one bed-room, and some two; but I do not know very much of their ways. I believe there are many cases in which there is a man and his wife and some little children, and they have not more than one bed-room. I believe that it is a very rare occurrence to take a lodger in that case.

1566. (*Chairman.*) Have you ever heard that men who have injured their feet while working, have suffered from the water they are obliged to stand in ? —No; I never knew anything of the sort.

1567. (*Mr. Fulke Egerton.*) Do the men usually work in shoes ?—Yes. I recollect one man that we had, of the name of Vincent, who used to say that standing in water would not agree with him.

1568. (*Mr. Kendall.*) Supposing you had a wound in your foot, would not the copper water do it much harm ?—I cannot tell you; but I have had many bruises in my feet, and pieces of skin knocked off, and I never found that.

1569. Take the case of a dozen miners, who were found to be in ill-health, should you think that their illness was to be attributed to bad ventilation, or to colds which they had caught from their own carelessness ?—I cannot tell you. I think that there are some cases that arise from one cause and some from another.

1570. Do you think that bad ventilation has more to do with it than anything else ?—I think that very bad ventilation would have to do with it.

1571. Is the ventilation so bad in the mines as, in your opinion, to have a bad effect, and, to a great extent, upon the health of the men ?—I think not, in our neighbourhood.

1572. (*Mr. Davey.*) Are you of opinion that the climbing of the ladders is beneficial or otherwise to the men ?—That depends upon how they take them. If they went on steadily and properly, as they might do, I should not think it would hurt them much; but if they were to go up them as I have done they might make it injurious to them.

1573. (*Chairman.*) I suppose that the men are naturally anxious to get away from their work, and come to the surface ?—It is not that altogether; but perhaps three or four get together, and they try to see which can get up the fastest.

1574. In point of fact they race up ?—Yes.

1575. (*Mr. Kendall.*) Have you observed any of the miners with enlarged veins in their legs ?—I cannot tell you; but this I know, that when I used to work every vein of my arms would show as plain as could be; but they do not show now. I recollect working and breaking the stones, and then I was able to take up a 9 lb. or 10 lb. mallet, and beat the borer with it then.

1576. I do not mean that; but this is what I mean, that after the men have been in the habit of going up and down the ladders, have you observed in their

LISKEARD.

Mr. J. Seccombe

15 April 1862.

legs varicose veins?—I never recollect anything of that sort in their legs.

1577. (*Chairman*). Do the men provide their own borers?—They take them out; they take out so many borers, which are weighed to them; they are put to book to such a pair; so much weight against a man, and then when his bargain is out, perhaps once in two months, if he is in the same place, he must send his tools to the surface, to have them weighed.

1578. Do you make deductions for the wear and tear in the borers?—Yes.

1579. Are the borers made of steel now?—Yes; there used to be a piece of steel put at the end of the bar of iron; but the whole of it now is made of steel.

1580. That, I suppose, is an advantage to the miner?—Yes; over the iron borer.

1581. He can do more work, I suppose, with the steel borer?—Yes.

1582. (*Mr. Davey.*) How far should you bore a hole before you cease to get any dust from it, and before you applied the water?—That would depend, of course, upon the inclination of the hole; some holes might go in nearly vertical, even to two or three inches deep, we should put water in that; but in holes that do not dip so fast we hardly ever put in the water until it will contain enough to cover the bottom of the hole, because then the fine stuff would come up, and would not settle at the bottom, and if it only got damp it would deaden the blow coming upon it

1583. Did you ever find any inconvenience from the dust coming into your mouth?—I cannot say that I have found the dust coming into my mouth. I have used a mop sometimes. I have known a piece rather softish, and over the ladder put below at cut cross place, the borer has been pushed through, and there it has been necessary to put a little bit of rag over to confine the dust.

1584. Do you think that the dust may be confined altogether?—I think it might, so that it should not injure a man in using a borer.

1585. (*Mr. Holland.*) Do the miners ever injure themselves by beating the borer?—I think that it might be done. I think that a man might, by overstraining himself, injure himself in that way, the same as in any other kind of work.

1586. But is it common?—I think it is a very rare occurrence.

1587. Do you think that the injury is not done by quick beating, but by overstraining themselves?—I do not know that any man ever got a pain by beating a borer. I do not say that it is not possible, in trying to see what he could do, by overstraining himself.

The witness withdrew.

Mr. WILLIAM RICH examined.

Mr. W. Rich.

1588. (*Chairman*). I believe you are captain at the Caradon Consols?—Yes.

1589. And you had been a miner for some years before you became captain?—Yes; ever since I was ten years old.

1590. Did you suffer from working in the mines, when you were young?—I have suffered inconvenience from the bad air.

1591. Have you known instances where there has been bad air?—Yes, certainly.

1592. Is the bad air caused by the want of ventilation?—Quite so.

1593. What is the depth of the mine?—Sixty fathoms below the surface.

1594. Are there more shafts than one in it?—There is only one shaft. We have made that one air-tight, and we divide it in the middle, so as to have clear ventilation.

1595. When you say you have divided it in the middle, do you mean that it is divided up and down?—Yes; and we have made it air-tight.

1596. How many men have you at the present time working underground?—Twenty-seven men.

1597. Are they all healthy?—They are very well, I think.

1598. What is your opinion as to the cause of the ill-health of the miners?—It is bad ventilation, generally, and the dust from the ore, and the powder-smoke, and various causes.

1599. Dust does come from the ore?—Certainly.

1600. And I suppose if there is mundic in it, it is much worse?—Yes; mundicky and copper are very bad.

1601. How does it affect the men?—It produces a tightness in the chest, and a difficulty in breathing; it loads up the lungs.

1602. Does it affect the general health of the miners, or what is the first symptom of illness in the miners?—Paleness in the face, shortness in the breath, and weakness in the legs, and a difficulty in climbing.

1603. Do you think that the climbing up the ladder has nothing to do with it?—It is a very trying thing, the climbing up deep mines; but the men need not climb so hard as they do; they can make it hard or easy, as they please.

1604. But do they not sometimes race up?—Certainly they do.

1605. Is not that injurious to them?—Yes.

1606. When a miner's health begins first to fail and he is then placed under the doctor's hands and recovers, does he return to the mine again?—Yes, very frequently; and he may be put into nice comfortable places, where he is unable to go underground.

1607. (*Mr. Austin Bruce.*) You have spoken of the men suffering. Have cases often come under your knowledge of men suffering as you have described?—I have seen men very frequently suffering, but not lately; I think it is not so very much. We have not one who is at present sick.

1608. Do you think that these sufferings are almost the necessary consequence of the men working underground, in the copper mines, or do you think they can be prevented?—There are places where it is impossible to obviate them.

1609. Why do you suppose so?—Because there must necessarily be bad ventilation; you cannot convey the air; it is very difficult, in a hollow piece of ground to do so; the machinery sometimes is inadequate for the work.

1610. Is it because it cannot be done, or because it is expensive to do it?—Sometimes it cannot be done and at other times it is expensive; but any man with reason will do all that he can to remedy it.

1611. I suppose there is a great difference between one mine and another, in the manner in which the ventilation is conducted?—Certainly.

1612. Has it been your business to view other mines besides your own?—Yes, several.

1613. Have you found in them considerable difference?—Yes, I have; just as there is in farming.

1614. But good farming and bad farming affect the profits of the farmer, but they do not affect the health of the labourers?—Just so.

1615. Well-managed ventilation would affect the profits of the owner, but it would also affect the health and lives of the men employed by him?—Yes, certainly.

1616. I suppose there is also a considerable difference caused by the skill or the ignorance of the different captains employed in the mines?—Yes. In some places there is not sufficient attention paid to the subject of ventilation as there ought to be.

1617. Where people are rather short of capital, I suppose, they do not take the same means to carry ventilation into the close ends that others do?—It is

not always the case that they are short of capital, and poor mines are sometimes as well ventilated as the richer mines.

1618. In cases where you have observed inferior ventilation, as compared with mines generally, what, in your opinion, has been the cause of it?—I do not know that I know of any particular case that is inferior. I have certainly seen places that might be improved.

1619. Your experience does not go very far back, for you appear to be young?—Yes.

1620. What is your age?—Thirty-six.

1621. Have you observed in your time any improvement in the general health of the miners?—I cannot say that I have.

1622. Are the arrangements for ventilation better now than they were when you first started?—They are just the same.

1623. You say that you have known your workmen suffering from the symptoms you described just now?—No, not one of ours.

1624. Where, then, has it been where you have perceived such symptoms?—In a very large mine, where they had a large number of men. Our men are very few in number, perhaps there might be one or two out of the twenty-five or twenty-six, but very few.

1625. How many workmen in a hundred would probably be affected as you have described?—Perhaps not one in a hundred.

1626. What is the age of the youngest man in your mine?—About seventeen.

1627. What is the age of the oldest?—About thirty-seven or thirty-eight.

1628. How does it happen that you have got so young a body of men?—We pick out good men; we have very few men.

1629. (*Chairman.*) Have you ever seen any artificial means of ventilation tried?—Yes, various means.

1630. Do you think that they have been tried with good results?—Yes, with great effect.

1631. Why should not the same means be employed for ventilating the bad ends?—The same means are employed in many places, where there are many men, and the air is not sufficiently good for a large number of men.

1632. What are the artificial means that you allude to?—It is to force the water, or pump it down, by fans, and things of that kind.

1633. Have you ever seen that done from the surface?—Yes; and at other times from the levels below, where the air is fresh.

1634. When it is done from the levels below, it is done by boys, is it not?—Yes, or by a stream of water.

1635. (*Mr. Kendall.*) You say that you are only 36 years of age?—Yes.

1636. Did you work your way up as a miner before you became an agent?—Yes.

1637. When did you first begin?—When I was 10 years old.

1638 How did you work your way up; as a tributer or as a tut-man?—In all gradations, all the way up.

1639–1640. What depth have you worked down?—Never below 200 fathoms.

1641. Was the air very hot at 200 fathoms down?—Yes.

1642. That was before you could get any connection between, I suppose?—Yes.

1643–1644. You have stated that the ventilation is just the same as it was?—I do not see much difference.

1645. As you have visited many mines, do you think that in many mines, from false economy, ventilation is neglected?—I think it is false economy where they do not do it.

1646. Have you seen the men working in bad air which might have been easily remedied by a small outlay?—Yes.

1647. Do you think that the agents are accountable for that state of things, or that the agents desire to please the adventurers?—I do not think that the adventurers ever control them.

1648. Generally speaking, do you find the adventurers are willing to do what they can for the benefit of the miners?—Yes.

1649. Do you think that the want of ventilation proceeds from false economy, or from want of thought on the part of the agents?—It is certainly false economy. They want to work as cheaply as possible.

1650. Did you ever see any man in the Caradon Consols Mine working where the candles burnt very dimly?—Yes. I have worked myself there, and there are plenty of shafts in that mine.

1651. Before there was any connexion, and before you sunk the winze?—Yes; when the winze was in the course of being sunk; just before the hole was made, we had better ventilation, and perhaps in a week or two things might be improved.

1652. But there I presume you contrived to get your air doors in, and so on?—Yes; they did everything they could, I believe, generally speaking.

1653. Have you often seen the men working in places where the candles would burn dim?—Yes, and they have been obliged to leave them.

1654. Have you known men who were notorious for working in bad air, and who suffered in consequence?—I have seen a good many men who were not at all particular.

1655. And they have suffered from it, have they?—Yes, certainly.

1656. But your experience leads you to think that not more than one man in 100 suffers?—I do not think they do.

1657. (*Mr. Fulke Egerton.*) I suppose that in most mines there are not more than two or three bad places?—Perhaps not.

1658. (*Chairman.*) Would the men who were working in these bad places forfeit anything by leaving their work if the air was bad?—Not at all.

1659. They would not suffer in their pocket by leaving their work?—If they refused to work their remedy would be simple; they could go away, and go somewhere else.

1660. But suppose they could not get employment?—That is the point; but they could not be long out. Able men generally can get employment.

1661. Generally speaking, do the men work on because it is their only means of obtaining a livelihood?—Yes.

The witness withdrew.

DAVID BUZZA examined.

David Buzza.

1662. (*Chairman.*) What is your age?—60.

1663. How long have you been working in mines?—I have been underground for 50 years.

1664. Where are you working now?—I am working in the mine that is called West Caradon.

1665. Have you ever worked in other mines?—Yes, in many.

1666. What is your work now in West Caradon?—I am on tribute.

1667. Do you prefer working on tribute as compared with tut-work?—Yes.

1668. Does it answer your purpose better?—It is not so bad for the air on tribute as it is on tut-work.

1669. Is that one of your reasons for preferring

LISKEARD.

David Buzza.

15 April 1862.

tribute?—Yes; with the advantage, perhaps, of getting a trifle more money at times. But what I have come here for this afternoon is this: I worked in a mine called Devon Great Consols, and my family is now residing at Tavistock. I have quarters here. I have been turned away, after I had done very badly for some months; 14 months; all that I earned during 14 months was 15*l.* 1*s.* 4*d.*

1670. Was that at Devon Great Consols?—Yes.

1671. You gave up work there?—I complained that I had done badly, and that I had not got money enough, and it was in their power to let me get more, and because I complained they turned me away out of that mine, and they would not let me work in any mine in the district. And so this is how a miner is tossed about. I went to the different mines in the district, and I could not get any more work. "I have no work for you," they said.

1672. Have you suffered in your health when you have been working in the mines?—Yes, I suffered rather.

1673. Have you suffered at all in your breathing?—I understood that this was for the welfare of the miners all through.

1674. But my question was whether you had ever suffered in your health from working the mines?—Yes, many times.

1675. How has it affected your health?—It has affected me in my breath.

1676. Do you feel the effects of it now?—Yes, I do feel the effects now; but I have not suffered so much so much as many.

1677. When did you begin first to suffer?—When I began to take a man's part; not when I was a boy.

1678. Did you go down under ground as a boy?—Yes. I went down, and came out again after working some time, and went home, and got into bed, and just when I came home I had no stomach to eat anything, and I would rise in the morning just like that, and was sometimes home for a month without working at all.

1679. Were you under the doctor's hands?—Yes; I have had a doctor; but I believe that the doctor is not of much service for men working in poor air; they call it the miners' complaint, after a man has done working.

1680. Have you got that complaint upon you now?—Yes; I have got a little of it; at times I have got a very bad cough and short breath.

1681. Can you go up the ladders now?—Very badly; nothing like what I used to do; but then there is one thing besides this, my age is great; I am an old man for a miner, 60 years of age; I was 60 last February.

1682. Are you now working at tribute work?—Yes.

1683. Are you doing well at it?—No; I have done very badly indeed.

1684. Are you working in a pair?—I have a boy working with me; we generally work one man and a boy.

1685. Are there no more than two of you as a pair?—Some are working four and some two.

1686. How old is the boy who is working with you?—He is 13 years of age.

1687. Is he a relation of yours?—No; he is quite a stranger.

1688. (*Mr. Kendall.*) What level are you working at?—I am working at level 38.

1639. What did you take up last month?—I have had since I have been there for the last six months 7*l.* 10*s.* for six months.

1690. For you and the boy?—No; for myself.

1691. When you were ill, what did the doctor give you for your cough?—Sometimes I got a few pills and a powder, and so on.

The witness withdrew.

Mr. RICHARD PASCOE examined.

Mr. R. Pascoe.

1692. (*Chairman.*) In what mine are you engaged?—In the Gonamena mine.

1693. Have you been a miner all your life?—Yes.

1694. And employed in this district?—Not all the time.

1695. But have you been employed in Cornwall principally?—Yes; and also some time in Devon, and a short time in Scotland, in the Kirkcudbright mines; and I was in Ayrshire for three years, and in most of them round this district.

1696. How long have you been in the mine you have mentioned?—I worked there for some years before I was agent, and I have been agent for six years; I worked there for five years before I became agent.

1697. What is the depth of that mine?—90 fathoms; that is, about 100 fathoms from the surface.

1698. Is it a well-ventilated mine?—Yes, it is. We have two shafts; one farther west and the other in the east.

1699. How many men do you employ in that mine?—There are 16 miners employed underground.

1700. Did you ever suffer in your health while mining?—Yes, I did; and it was from working in the poor air I have suffered.

1701. What was the effect produced upon you?—You feel it in your knees, and you have shortness of breath, and a pain in your head.

1702. Did you get well again after you left the mine?—Yes.

1703. Did you go back again to work in the mine?—Not into the poor air.

1704. How do you ascertain the presence of poor air, otherwise than by its making you feel unwell?—By the candle; and when you come into good air you feel it directly. You have a pain in your head, and pains in your legs.

1705. You do not feel it so much while you are working?—No.

1706. Do you only judge of the presence of bad air by its effect upon the candles?—Yes; at the time you are there.

1707. Were you in the habit of leaving off work when the candle began to burn dimly?—No. I have worked there many times when we could keep no light.

1708. Why did you go on working under such circumstances?—Because I was anxious to get more money. It was very foolish; but when a man can get a little extra money he will work a little more.

1709. Do you mean that they will work when the candles will not burn?—Yes; and if we wanted to ventilate one place to another we should just work a little more. I have run the risk of my life to work a little more to get the place well ventilated.

1710. Are the men paid for doing that?—Nothing.

1711. If you had given up the work, I suppose you would not have been paid?—Yes. We know that it must be done, and that we must go and do it, thinking that an hour or two more would not hurt us.

1712. But still you have suffered from the effects?—Yes. I did not work in it long; just for some hours, and then go off.

1713. Did you ever go in for a few minutes to work, and then come out to get fresh air?—Yes.

1714. Are there no means of bringing in fresh air to such a place as you are speaking of?—There are many places like it that might be better ventilated if they only went to a little extra cost, by having timber sawed up thin, and put over the air soliers in the bottom of the level; that would convey the air.

1715. By that means you would form a current of air ?—Yes.

1716. Have you seen pipes put in for that purpose? —Yes ; they have put them in in one mine; we drew out 150 fathoms with air sollers.

1717. Were they made of iron or of wood ?—Of wood.

1718. Have you any artificial means for forcing the air down from above into those places ?—No ; it is ventilated from one level to another by winzes ; they make the air go in over and come back again over.

1719. Why is that not always done ?—It is the expense ; very often it might be done better with more expense.

1720. If the men complained, do you not think that they would do it ?—They might in some cases.

1721. Would it not also be for the advantage of the owners of the mine ?—Yes, in many cases it would.

1722. Do you think that the matter is not brought under the notice of the owners themselves ?—I think that the men are driven to it very often by the agents to work extra ; to do a thing where they have not work in another mine ; and if they have not this place they do not know where to go and get their living ; it is like that in many cases.

1723. (*Mr. Kendall.*) When you say that they are driven to it, I understand you to mean in this way, that a man goes to an agent in a mine, and says, " Can you give me any employment ?" The agent says, " I do not know that I want any men ; but " there is such and such an end, and if your will try " that you may," and the man takes it ?—Yes.

1724. That is what you mean ?—Yes.

1725. And in an end of that kind you say that the outlay of a small sum of money would produce better ventilation ?—Yes.

1726. Did you ever know a case of an agent being asked to make a small outlay of that kind, and refusing to do so ?—No ; but I do not know that a man would venture to ask that. I do not mean that the captain would oblige a man to go there, but the man's circumstances may be such that he does not know where else to go and get his living.

1727. That is to say, the captain does not say, " You must go and work in that place," nor, " If you you will not work in that place I will turn you off," but if a man wants employment the agent may say to him, " There is such and such a place ; you may " try it," and rather than not work at all the man will run the risk ?—Yes.

1728. And you are of opinion that the outlay of a small sum of money would prevent that risk ?—Yes, oftentimes, but sometimes it could not.

1729. Do you think it has not been done because a man has been afraid to ask an agent for fear he should he dismissed ?—Yes.

1730. But you never knew an instance of a man asking an agent and the agent refusing ?—No ; but I do not think that a man would venture to do it.

1731. (*Mr. Fulke Egerton.*) Are the agents constantly going over the mines ?—They should do so ; the agent has to go into every place ; wherever a man goes the agent has to go ; but a few minutes will do it.

1732. (*Mr. Davey.*) Are you not aware that they pay an additional price to the workers for those ends where there is poor air ?—Yes ; that is because a a man cannot work so much.

1733. For example, if you could drive an end for 4*l.* a fathom, provided it was in good air, you would pay 6*l.* a fathom for driving it if it were in foul air ? —Yes.

1733. (*Mr. Kendall.*) Do you know any instances at this moment of any men working in that way ?— No ; I have not been in any mine to see anything of that kind for some years. Our mine is at present well ventilated, and most mines of late have been so.

1735. Do you think the mines are better ventilated than they used to be ?—Yes, I do think so.

1736. Has there been great improvement in them in that respect ?—Yes. I know that South Caradon and West Caradon have been considerably improved in the last few years.

1737. Would you get many men at the present time to work in bad ends ?—Yes, I think so ; they would work there now rather than remain out of work.

1738. (*Mr. St. Aubyn.*) By what means has the ventilation been improved ; has it been by making additional winzes, or in what way ?—By causing more ventilation, by winzes, and holing the mines, holing one mine into another. West Caradon and South Caradon are ventilated one from another, and by that means a current of air is carried through all the mines.

1739. That is by connecting one mine with another ?—Yes.

1740. Speaking of a mine that has no connection with another underground, are you of opinion that the methods of ventilating have improved ?—No, not in all.

1741. (*Mr. Austin Bruce.*) Are there many men who are now suffering from working in bad places ? —I do not know of many now.

1742. I do not speak generally of your own particular neighbourhood, but within the district with which you are acquainted, are there, in your opinion, many men suffering as you have described ?—Perhaps not many, but of course working underground is not like above ground ; a man cannot live and work as long under ground ; they want a change of air ; they are down amongst the powder smoke and candle smoke, and certainly that will injure a man. If I go down for three or four hours, when I come up again I spit up all the black smoke.

1743. Even now, when you are not in the habit of working below ?—Yes.

1744. And that would of course be worse for the men, who are exerting themselves in their work, because they breathe faster?—Yes ; and they take in more of that candle smoke, and that is very bad ; but the men do injure themselves often when they need not do it, by running into the powder smoke, when they are very hot to see what has been done ; they rush into danger when they ought not to do it.

1745. Have you ever seen any close end into which sufficient ventilation might not be carried at some inconsiderable expense ?—Yes ; I have seen it where you could not ventilate a place ; I have seen ends of that sort.

1746. From what cause was that ?—Because the air was entirely dead all round, and you want to hole two places from one shaft to another, and you will get it so that you cannot throw the air in. There is no such thing to be done as to put a machine in ; and the men have to work in times like that.

1747. Are there no artificial means which could be resorted to for throwing air into those places ?—Not without incurring a great expense. There are times when you cannot ventilate.

1748. And those are the instances I presume in which there is the most suffering ?—Yes.

1749. I suppose, although you have ceased to be a worker, you have kept up your acquaintance with workmen ?—Yes ; with a great many.

1750. Do you know many of them who are suffering from the effects of working in bad air ?—No, I do not know many now.

1751. You have described the state in which you have been yourself when you have gone on working in bad air. If you have felt the inconvenience of that, do you imagine that if you had continued that kind of life you would have been in as good health as you are now ?—No. I should not be living now.

1752. And there must have been many more miners in your position ?—Yes ; but they would not work in those places long ; they could not.

1753. The instances in which you worked in bad

places were not the ordinary instances, but the exceptions ?—Yes.

1754. Were the exceptions frequent enough to tell upon your general health ?—They told upon my health, and I was bad for a while, so bad that I could not work so well ; I was not so strong, and then I would go into the good air again.

1755. If you had not possessed sufficient intelligence to raise yourself to your present position, and had been obliged to lead the life of a working miner, do you think you would have been in tolerably good health now ?—I should not work in those places. There are ways, if men will just put themselves to work upon tribute ; but men have not sometimes courage enough to turn from tut-work to tribute-work. They do not understand the work, and they refuse places. But if a miner were sharp enough, he might work at tribute, and that is generally in good air.

1756. But still somebody must do the bad work ?—Yes.

1757. A sharp man and a clever man might avoid those places ?—Yes.

1758. But still somebody must go into them ?—Yes.

1759. So that there is unhealthy work going on in most mines ?—Yes ; in most large mines.

1760. (*Mr. Falke Egerton.*) I understood you to say, that in some mines the unhealthy work was unavoidable ?—Yes ; in large mines.

1761. I suppose that those are places that are being driven onwards ?—Yes.

1762. Eventually they will become well ventilated ?—Yes ; after a while.

1763. How long do you suppose that they will remain in an ill-ventilated state ?—I cannot tell you that.

1764. (*Chairman.*) Does it take sometimes as much as two or three months to complete a communication ?—Sometimes two or three months.

1765. Does it ever take as long as six months ?—Yes ; to ventilate a good place.

1766. In the meantime the air in that place is bad and unwholesome ?—Yes; and then it gets worse ; and it will continually get worse until you just bole further in ; but very often places might be better ventilated by incurring a little extra expense.

1767. (*Mr. Davey.*) What proportion of the people in a mine would be working in bad air ?—Perhaps not one in 100 ; it is only at times that you find a place like that.

1768. (*Chairman.*) Are many of those miners who worked with you at the time you have referred to now dead ?—Yes ; several of them have died.

1769. At what age did they die ?—At about 30 or 40 ; they have killed themselves in that time. My father died at 44, and I believe all through breathing poor air.

1770. Have you any tut workers now ?—Yes.

1771. Where are they working now ?—They do not work in the poor air ; they would not.

1772. Should you say that it was more generally the needy miners who undertake this kind of work ?—Yes ; they are forced to work at it. Take the case of a man with a large family ; he is afraid to leave tut work. When you have tribute work you get what you can. A man works upon little, and that keeps him under water always ; and if he cannot go to tribute, perhaps his judgment is not good enough to enable him to know when he takes a good place.

1763. Have you never seen any means by which air could be forced down into those bad ends ?—Yes; it could be done by an engine ; by putting in an air machine to be attached to the engine, that will blow down the air, and force it in. We have put in machines to throw it down 120 fathoms, so that we might keep 20 men at work by it.

1764. You would get a supply of good air by these machines, so that 20 men would be enabled to work ?—Yes.

1765. How is the air conveyed along ?—In wooden pipes or in zinc pipes.

1766. Have you tried zinc pipes ?—Yes.

1767. Does not the zinc soon decay ?—That depends upon whether the water is coppery ; if it is, it will eat it out very fast.

1768. Did you ever try gutta percha ?—No.

1769. The water would have no effect upon that ?—No ; but I never saw it tried.

1770. Do you not think that it might answer ?—I should think it would, and keep the air very sweet.

1771. You would also have the advantage of being able to move the gutta percha pipes from one part to another ?—Yes. Where there is an engine you can throw the air anywhere up or down ; that could be done ; and they might ventilate many mines better than they are, if they went to a little expense in a machine.

1772. Has your mine got one of these machines ?—Yes; we have done it by air sollers. We have thrown down good air 150 fathoms ; we have thrown it by machines 120 fathoms, which I think would supply 20 men.

1773. (*Mr. Austin Bruce.*) Would not that reach any close end that you have seen ?—Yes ; but those close ends may not have an engine. It might be so in little mines, where there is no engine.

1774. (*Chairman.*) If you had had an engine, you could ventiate any close end ?—Yes ; anywhere.

1775. (*Mr. Davey.*) I think you stated just now that it was only the needy men who would work in these close places ?—Yes.

1776. Are they not likely to be the greedy miners who do so ?—No. I do not think that they get so much on the average. I have worked in those places where there has been bad air, and when I have had a good pitch, I have been a little greedy to ventilate the place ; I have worked some days to get the place ventilated.

1777. (*Mr. Austin Bruce.*) You stated that you had been working in Kirkcudbright and in Ayrshire ?—Yes ; in Kirkcudbright it was in copper mines, and in Ayrshire coal mines.

1778. As compared with the Cornish miners, which are the most healthy class ; the Scotch or the Cornish ?—The Scotch miners were very healthy, and the mines were chiefly ventilated by sollers ; I saw it done there.

1779. Was there any difference as between the copper mines in Kirkcudbrightshire and the collieries in Ayrshire ?—There was no comparison to be made between the two ; the copper mines were the healthiest.

1780. Why do you think that was so ?—Their works were not extended so far ; it was not so deep ; there were no copper mines in Kirkcudbright that were deep ; the deepest was 30 fathoms.

1781. Were the collieries well ventilated ?—Yes, pretty well ; not well, but just middling. You could not complain much.

1782. (*Mr. St. Aubyn.*) Were you ever employed at South Caradon before it was connected with West Caradon underground ?—No.

1783. How do you know that the miners enjoy better health than they did formerly ?—Because all the miners are thrown together now.

1784. Were you there at that time ?—Yes. One was partly ventilated from one place ; but since I have been there it has been ventilated all over.

1785. Did you know the miners before the mines were connected ?—Yes.

1786. The health of the miners is better now than it was then ?—Yes.

1787. You think that it is on account of the air being better that the miners health has been improved ?—Yes.

1788. Have you no man engine there ?—No ; we are connected only 90 fathoms deep below the adit.

1789. Is the adit 10 fathoms ?—Yes.

1790. (*Mr. Holland.*) Did you ever work in cold damp air?—Yes, a little, but not much.

1791. I mean when you could not keep yourself warm?—Yes.

1792. Is that a very rare occurrence?—Yes.

1793. Did that very quickly make you poorly?—Yes; it will make you bad very quick.

1794. Did you completely recover from that after working some time underground?—I believe I was completely recovered.

1795. Have you no cough now?—Nothing more than from cold; I do not feel anything from it I think. LISKEARD. *Mr. R. Pascoe.* 15 April 1862.

1796. Have you known of many people recovering often being considerably affected by the poor air?—Not many; not after working in it a good while; I never did.

1797. They never recover completely, do they?—No; they might have worked a little, but they never get well enough to be sound men.

The witness withdrew.

Adjourned till to-morrow at half past 10 o'clock.

Wednesday, 16th April 1862.

PRESENT:

The Right Hon. Lord KINNAIRD, K.T.	H. AUSTIN BRUCE, Esq., M.P.
The Hon. A. FULKE EGERTON, M.P.	P. H. HOLLAND, Esq.
NICHOLAS KENDALL, Esq., M.P.	RICHARD DAVEY, Esq., M.P.

The Right Honourable Lord KINNAIRD, K.T., in the Chair.

A MINER examined.

1798. (*Chairman.*) You are at present employed, I believe, as engine man?—Yes. *A Miner.* 16 April 1862.

1799. How many years have you worked in mines?—About 28 years.

1800. How long is it since you have given up the underground work?—The last time about eight years.

1801. At what age did you commence work?—I commenced work, I suppose, at the age of 10 years.

1802. I suppose you did not go under ground then?—No, but I was at the surface; I went under ground, I suppose, at about 13 or 14 years of age.

1803. Did you work principally as a tributer or as a tut-work man?—I worked for many years as a tributer, both as a tributer and at tut-work.

1804. Which work did you prefer?—I preferred to work at tribute.

1805. What was your reason for preferring it?—It is generally more healthy; there is better air, and in addition to that it is generally day work, not so much working by night as by day; but my chief reason is that it is better air generally.

1806. There are three corps, are there not?—Yes, at tut work.

1807. Do they change about from night to day, or do the night men always work at night?—There are six men, two in a corps, the men that would work forenoon this week would work afternoon next week, and the night corps the following week, so that they always change over.

1808. Did you ever in any mines in which you have worked experience inconvenience from the poor air?—Very much so; that has disabled me from working under ground; I was obliged to give it up for that reason.

1809. In what mines did you work?—I have worked in various mines, and I have suffered inconvenience from the air.

1810. Have you worked in large mines?—Yes.

1811. Will you mention any one mine?—I have worked in South Caradon since I have been in the neighbourhood.

1812. Before that did you work in another part of Cornwall?—Yes, I worked in the Polberro Consols at St. Agnes.

1813. When did your health fail?—My health first failed about 14 years ago.

1814. Which mine were you working in then?—I worked in a little mine then on first going into this neighbourhood, nearly 20 years since, the Caradon Consols; they were then driving an adit level, and it was driven for 125 or 130 fathoms; there was no shaft, no draught.

1815. Were there no artificial means of ventilation?—None whatever. That was the first mine that I worked in when I came into this neighbourhood, nearly 20 years since.

1816. What height and breadth was the adit of 130 fathoms driven?—It was perhaps from 3 feet to 3½ feet in breadth, and from 6½ feet to 7 feet in height.

1817. For that distance there was no winze or any means of natural ventilation?—None whatever.

1818. No air was forced in by any machine?—None whatever. There was first a cross cut of perhaps about 90 fathoms, then it intersected the lode, and afterwards it was driven perhaps 20 fathoms or 25 fathoms on the course of the lode. Then there was a turn which made it so much worse, and after driving perhaps 25 fathoms on the lode, then there was a cross cut again, a turn again from the course of the lode under the engine shaft. That cross cut had to be driven perhaps some 20 fathoms, and it would come in contact with the engine shaft.

1819. The object was to reach the engine shaft?—Yes.

1820. But till you reached that shaft there was no communication of air?—None whatever.

1821. How many men were working in that end—Six men, two at a time.

1822. Did you test the air at any time to see whether it was poor or not?—We had the candles to test it, we applied the candles, and they would not burn standing upright; we were obliged to keep them on the side.

1823. They would burn if kept on the side?—Yes, but not standing upright.

1824. Did you ever try whether it made any difference whether the candles were kept high or low down in the end?—It will make a little difference when there is a stream of water coming out of the end, it will make a difference in the bottom of the level, the air is then a little better.

1825. But there was no stream of water sent down from the surface?—None whatever.

1826. For how many hours did you work at that time each corps?—Eight hours.

1827. Was there any time between when the first corps left and the second corps succeeded?—We were expected to relieve each other.

1828. At once?—Yes.

1829. For how long did you work in this bad air?—I worked perhaps six months, many others had worked previously to my coming there. I think that I took the place of a man who had been so disabled that he had to give up work, and he died in consequence.

1830. Did you know at the time when you took that work that it was likely to affect your health?—Of course I knew that the air was not sufficiently

LISKEARD.

A Miner.

16 April 1862.

good, still being a young man I did not feel its effects directly, and of course I thought that it would not have injured me, but shortly afterwards I felt its effects.

1831. About when did you begin to feel bad air? was it when you first went to work?—Not at first.

1832. What distance should you say from the shaft was it that you began first to feel the bad air?—I believe that I began to feel the effects of the bad air perhaps 20 fathoms from the shaft.

1833. The candle was affected?—The candle was affected at perhaps more than 40 fathoms, 50 fathoms before it reached the shaft.

1834. Was there any difference on entering that end on a Monday morning from entering it on any other day?—Very much. In working on the other days there would be the powder smoke and the candle smoke which would be confined in the place; there not being a sufficient body of air, it would not live; it would die in the place; and on Monday mornings, of course, having been absent from Saturday, all this would naturally have gone away.

1835. How long should you suppose that the powder smoke, when you were working, remained in that end?—It was never clear of powder smoke from Monday morning until Saturday night, being continuously working through the week.

1836. How many blasts do you suppose were driven during the day in that end?—We generally calculated to blast three holes each corps—sometimes it would be more.

1837. So that in the 24 hours there would be nine blasts?—Yes.

1838. Was it a dry end or a wet end?—It was a dry end.

1839. Was there any dust at all in driving?—It is naturally so where it is dry.

1840. Whether you are driving by pick or by bore in a dry end there is dust?—Yes, naturally.

1841. But I suppose that you endeavour to keep it down by applying water, do you not?—If we are boring a hole, if we can conveniently do so, we use water.

1842. But sometimes, I suppose, you cannot get the water?—Sometimes we cannot get the water into it. If we are boring a hole where it is flat we cannot, but if we are boring a hole in any direction where it dips a little, we can get water into it. In boring a flat hole at the back of the end, or at the roof of the end, we cannot get water into it.

1843. And, therefore, there is a good deal of dust?—There is naturally dust.

1844. Do you think that you inhale that dust?—Yes; I had a very serious illness, for between two and three years I could not work at all. I never did a day's work for more than two years, and for years after I was unable to work again. I spat up a black substance, supposed to be the candle smoke and the powder smoke having been inhaled and lodged in the stomach or upon the liver, or something of the sort. For years after I declined working under ground I spat up this black stuff.

1845. Did you go on constantly doing it?—Yes, every day, for years after I had declined working underground.

1846. Do you know whether the other men who were working with you were affected equally?—The man that I worked with worked very little after leaving off working in this place.

1847. He died?—He died some two or three years afterwards.

1848. Then the reason why men work in those places is, in the first place, because they think that they may escape injury, and in the next place they do it, because it is the only means of earning their livelihood?—Yes; the principal thing is, that it is their only means—if they left that place, they would not know where to get another.

1849. Do you think that they are paid more for working in that air?—I believe that, generally speaking, they are not paid so well. There is not that difference made in the price which they get for excavating the ground which there ought to be; the badness of the air is not taken into consideration generally as it ought to be.

1850. Was this represented to the managers or captains of the mines?—They were perfectly aware of it.

1851. And yet they took no means whatever to supply you with fresh air?—No, they did not at the time; not until they came into communication with the engine shaft.

1852. I suppose that you paid club-money at that time?—Yes.

1853. Did you get an allowance during the year that you were laid up?—None whatever from the mine; we get no allowance from the club unless there is a visible injury.

1854. Then it is not if a man is put off work from the effect of the work?—No.

1855. You mean by a "visible injury," an accident?—Yes; a broken limb, or something of that sort.

1856. Is that the case, as far as your knowledge goes, with regard to other mines? Is the club-money not given to men who are off work from illness?—Not generally speaking; there are a few exceptions, but, generally speaking, they receive nothing.

1857. Who is the judge whether you are entitled to this relief or not?—The agents generally.

1858. Does the other 9*d.* which you pay for the doctor include attendance on the family?—Yes.

1859. Did the doctor attend you during that time?—Yes; but still we derive a very considerable inconvenience frequently from paying the doctors in that way.

1860. Why?—We frequently think that they do not pay sufficient attention to us as they otherwise would do, provided it was managed in some other way; it is frequently complained of. During the former part of my illness the mine doctor attended me; but after some time I did not recover perhaps as fast as he could have desired, and I had to apply to another. I had to go to Plymouth to the physicians there.

1861. Did they do you any good?—Yes.

1862. Do you feel the effects at the present time?—Yes.

1863. Can you go up the ladder with equal facility to what you could?—No, I feel a want of breath.

1864. How old are you?—I am in my 40th year.

1865. Do you know many miners of that age or older than that?—Yes, there are several who are of that age.

1866. Do you know many working in mines under ground at present of that age?—Yes.

1867. Have they suffered?—Yes, they suffer more or less. There are not many miners, at the age of 45 or 50, but who suffer either more or less from what they term the miner's complaint, that is, a tightness and shortness of breath.

1868. Did it seize you suddenly at all?—No, I felt myself declining for some months before I was obliged to give up work.

1869. You felt a weakness?—Yes, a natural weakness.

1870. And was that aggravated by climbing the ladder?—Yes, I had very great difficulty in climbing the ladder. If we are working in a poor air place, we generally find it out first in climbing the ladder; we generally find it out first in our legs and knees failing us; after working we generally find a very great pain or weakness in the legs and knees in coming up the ladders.

1871. Which would not be the case if the men were not working in poor air?—No, we do not suffer to anything like that degree when we are working in good air.

1872. So that that is one of the symptoms of poor air?—Yes.

1873. Is that known as a general symptom?—Yes.

1874. Do the men when they have that feeling leave off that work?—No, if they were to leave off that work they would not know where to go or what to do in order to get a livelihood for themselves and their families.

1875. Therefore, although they know that this may be fatal, necessity compels them to work?—Yes, of course many men work until they are obliged to give up. I knew perfectly well the last time I was under ground that I should have to give it up; in fact, I never experienced such a difficulty before or since as I did that day; I worked so long that I could really do no more.

1876. Did you ever catch cold in coming up?—Very likely I have done so frequently.

1877. Was there a changing house at this mine where you worked?—In the first mine that I worked in we changed in a barn belonging to the farm on which the mine was; we had no fire in it.

1878. Where you last worked, what was the description of dry?—There was no dry then; there was a changing house, but it was not a dry house; there was no fire, and no provision was made for drying the clothes; so that frequently, if our clothes were very wet, we had to carry them to the smith's shop, and hang them about, or throw them about wherever we could.

1879. So that if you came on a wet day to your work the clothes which you took off would be wet?—Yes, they would be the same when we came up.

1880. And you would have to put on those same clothes?—Yes; there were no means of drying them.

1881. But there are some places where there are those means?—Yes; in many mines provision is made for drying the underground clothes; but there is not that attention paid to the clothes of the men which they wear to the mine; they are not considered. The man who looks after the dry does not consider that he is requested to pay attention to these clothes, generally speaking.

1882. The man who looks after the dry only looks after the mining clothes?—Yes.

1883. If your clothes are wet when you come to the mine, he does not look after them?—He does not dry them.

1884. Not even in the dry house?—No, it is not generally done.

1885. How far were you living from the last mine where you worked under ground? Did you live in Liskeard then?—Yes.

1886. (*Mr. Kendall.*) You were speaking of the poor air at 90 fathoms, and then you mentioned 25 fathoms and an angle, and another 25 fathoms and another angle. In your experience, did you ever know either before or since such a distance where a man could even live?—I never found such a distance in any other place.

1887. Is it not a very rare thing?—Yes; it does not often occur, but it frequently occurs in mines, that it is driven a very considerable distance from any draught.

1888. But it is a very rare case to go in even 50 fathoms without some little help?—No, not at all; it frequently occurs to go 50 fathoms, and a great many fathoms more than that, without any communication of air.

1889. What was the nature of the ground; was it slate or granite?—Granite.

1890. Were you able, upon an average, to make three blasts each corps?—Yes.

1891. What was the general price of your end?—From 5*l.* to 7*l.* or 8*l.*; it was not violently hard ground.

1892. Where had you been working before you went to that place?—I worked at the Polbero Consols at St. Agnes.

1893. What level did you work in there?—It is shallow there, perhaps about 30 or 40 fathoms from the surface.

1894. There is no bad air there?—Not generally speaking; it is principally a tribute mine, and there are more shafts; there are a great number of shafts in that mine.

1895. Are you one of a family of miners?—was your father a miner before you?—Yes.

1896. What aged man was he when he died?—He was about 52 when he died.

1897. Was he an agent or a miner?—A miner.

1898. Did he die from any disease?—He died in a decline; he was not able to work under ground for some three or four years before his death.

1899. What age were you when he died?—I was about 26.

1900. Were you strong as a young man?—Yes.

1901. Very strong?—Yes.

1902. And healthy?—Yes.

1903. With no cough at all?—No.

1904. Were you sober as a young man?—Yes.

1905. You say that the agents were perfectly well aware that you were working in bad air?—Yes.

1906. Was the company a poor company?—No.

1907. They could have afforded to put up means to improve the air?—Yes; they afforded to put up an engine afterwards, and worked it for some time, but there was no engine in the mine at the time.

1908. Why do you think that the agents allowed you to work in that air—what was the object of forcing you on in that way?—Their object was, I suppose, to communicate with the engine shaft.

1909. Why would they not go to the expense of having a fan or something or other?—It was not above 15 fathoms from the surface, so that they might have put down a small shaft or two with little expense.

1910. And that small expense was spared?—Yes.

1911. You think that they ought to have gone to that expense?—Yes.

1912. In fact, it was economy that did it?—Yes; it was saving on their parts, no doubt; they might have done it with very little expense; they might have put down two or three shafts in that distance, and it would have proved of very great benefit to the men working.

1913. You say that you worked in South Caradon once?—Yes.

1914. South Caradon has become an extensive mine?—Yes.

1915. Was it an extensive mine when you worked there?—Yes.

1916. Taking the ventilation of that mine as a whole, was the ventilation very fair?—Some places were bad; but, generally speaking, I suppose that it is as good as the average.

1917. Were there many places where candles would not burn well in South Caradon while you were there?—Yes.

1918. That was before they ventilated it by winzes and so on?—Yes, there were not as many shafts in South Caradon at that time as there are at present.

1919. Were any means taken in South Caradon of forcing in air at those bad ends?—Yes, there were many places; they had got a small fan machine, but frequently the air forced in by these fan machines is impure where they take it; they do not take it direct from the shaft; it is not so pure air as it should be; they take that air at a certain place in the level, when it ought to have been taken from the shaft generally; so that it is not pure air that is always forced in by these fan machines.

1920. Did you know any place in South Caradon while you were there, where, at a moderate expense, they might have forced in air and did not do it?—Yes, in the last mine that I worked in.

1921. (*Chairman.*) Was that South Caradon?—Yes.

1922. (*Mr. Kendall.*) That was not where you first worked?—No, that was the Caradon Consols.

1923. What end did you last work in?—The 120 fathoms level.

1924. How far were you then in beyond any communication with the air?—We were in perhaps 40 fathoms from the shaft, and there was an angle in the level, and we had to drive on the cross course to

LISKEARD.

A Miner.

16 April 1862.

intersect the lode, and it was a timber level; we had to put in timber into that level, and that makes the air so much the worse.

1925. Then were you in 40 fathoms before you had an angle?—No, not 40 fathoms before the angle, but perhaps 15 fathoms from the shaft before the angle.

1926. And how many fathoms after the angle?—25 fathoms.

1927. How far was it before you made any communication?—At that distance they cut a lode and then sank a winze on the lode to the cross level.

1928. In sinking that winze the communication was still only through this drift?—Yes.

1929. Was the air bad in that winze?—Yes.

1930. How many men were working in that winze?—Four.

1931. You had eight hours' rest?—Yes.

1932. After you had rested was there a perceptible difference in the air?—Yes, there was a very great difference in the morning.

1933. A supply had come in?—There was a better supply; there was not the same foul smell. The candles are generally not of the best kind; the wick of the candle is frequently made of hempy stuff, when it ought to be of the best cotton. We frequently consider that the candle smoke does us as much or more hurt than the powder smoke.

1934. Before you communicated the air was very inferior?—Yes.

1935. How long was it after you began to work before you found the candle show a difference?—Not very long, two or three hours perhaps, and even in the first commencement it would not burn so clearly as in the good air parts.

1936. You were obliged to blast in the sinking?—Yes.

1937. How long was it before the smoke got out?—It would never get out at all while we continued working; before the smoke of one hole was gone, or, as we term it, died away, in the place, we had to blast another, so that in these poor places we are constantly working in smoke either more or less.

1938. Might the agents at a small expense have supplied you with better air?—Yes, they might have put in a waterfall from the engine shaft.

1939. Was any remonstrance ever made to them?—Frequently.

1940. And what did they say?—The reply is, "If you do not like it, you must leave it."

1941. Do you recollect what you got a fathom for sinking in the winze?—I did not sink more than two or three feet before I was obliged to give it up. I was laid prostrate.

1942. (*Chairman.*) Can you give us the names of any miners who are now working in an end with poor air?—Not at present working underground, I cannot, perhaps, give you the necessary information at present.

1943. (*Mr. Kendall.*) Take an average of the South Caradon mine, how many men do you think there are working underground there at a rough guess?—I cannot tell, I cannot answer the question now.

1944. When you were there how many were there?—I suppose there were 300 men underground when I was there, I think I am safe in saying that.

1945. How many of the 300 do you think were working in a bad end when you were there?—It would be difficult to say the number.

1946. Were there half a dozen men working in bad ends?—Yes, a great number more than that, unquestionably; it would be a very rare thing to meet with a mine of that description without finding a great number more than that working in a bad end at any time.

1947. (*Chairman.*) How many men are working in the mine where you are employed now?—I think I was informed some week or two since, that there are 300 men working underground there.

1948. Are there any bad ends with poor air in that mine?—I am not prepared to say exactly, there was one some time since, that was driven perhaps, about four score fathoms from the shaft, after being driven, perhaps, 60 fathoms they had a communication of air, what we term a waterfall from the shaft.

1949. (*Mr. Holland.*) How many years have you worked as a miner?—About 28 years I have been working in mines.

1950. You say that you have worked in ends where the candle would not burn unless it was sloped?—Yes.

1951. How often has it occurred to you to be obliged to do that?—Very often.

1952. How often at a time?—For twelve months at a time in many places—for many months at a time frequently.

1953. How long was it before the working in bad air began to affect your health?—Perhaps five or six months; I am not prepared to say exactly. In the first place that I speak of, it was stopped for some little time, and we worked at sinking an engine shaft, after being working there some five or six months. I am not prepared to say to a month exactly.

1954. Do you mean to say that for the whole day you had to slope the candle?—Yes, the whole eight hours.

1955. And could you work eight hours in such air continually?—Yes. When we had blasted a hole, perhaps we might go out into the fresh air there, but in many places in the old parts it would be too far down from the surface; but there we could go out from the end, because this level being taken up from the surface, we could go out and remain perhaps ten minutes or a quarter of an hour while the worst of the smoke was on, the heat would subside a little bit. In deep mines of course we had not that chance.

1956. (*Mr. Davey.*) You have been asked whether you yourself know of any place similar to the one that you have spoken of where there was such a length of level without any communication or any attempt to put in air?—I do not know any place at present.

1957. Have you ever heard of such a place before?—I cannot call to recollection such a place, but it frequently occurs in driving a level that men have to work in bad air for many months successively.

1958. You do not know any place so bad as that?—No.

1959. You say that you blasted about three holes in a corps?—Yes.

1960. How could you manage to do that when the air was so bad?—We were obliged to do it; we managed to do it; we had to make the best of the air.

1961. Is it not very unusual for a man to go in and bore another hole before the smoke has in some measure dispersed?—I have stated that we might perhaps stop ten minutes or a quarter of an hour between, but it is not at all unusual for men to go in after that time and work again.

1962. Do you not know that the smoke in a level of that kind will not disperse in a quarter of an hour, or anything like it?—I have said that it did not disperse; we always worked in smoke.

1963. From the experience which I have had I think that it is a moral impossibility for any man to go and bore a hole in a close end of that description in so short a space of time as you speak of, namely, a quarter of an hour—I have never seen anything like it?—It is frequently the case.

1964. What wages did you get whilst you were there?—Perhaps from 3*l.* to 3*l.* 5*s.*, or 3*l.* 10*s.*

1965. And what were the ordinary wages at other places at the same time?—It might have been just the same perhaps.

1966. Was it quite as much as that?—Yes, I believe that it was rather more, generally speaking; and especially in South Caradon, at the time it was considered more.

1967. Did not you get an extra price for working there?—No.

1968. You spoke of the candles being of a bad quality?—Yes.

1969. Do you know that if the candles were made of the best cotton they would not give you any light underground ?—Yes, provided that the wicks were sufficiently large.

1970. But the cotton itself in air, such as you have described, would not give any light ?—In some mines they have the cotton wick.

1971. (*Mr. F. Egerton.*) I understood you to say that you look after the engine ?—Yes.

1972. It is a steam-engine ?—Yes.

1973. Is the boiler-house used as a drying-house ?—No.

1974. There is another house used as a drying-house ?—Yes.

1975. Is that heated ?—Yes.

1976. From the engine ?—No, it is heated by a fire in the same house.

1977. Is it under the same roof as the boiler-house ?—No, it is apart from the boiler-house. There are iron pipes which go through the entire house, so that it is heated at either end; there is a fire-place at each end of those pipes.

1978. Then the men can dry their clothes there ?—There is one man by day and another by night, in order to dry the underground clothes ; they are dried in the same house where the men change.

1979. In what state are your boilers ?—The boilers are in a very good state.

1980. Do you know anything about the boilers generally which are in use at these mines ; are they generally old boilers, or are they bought new ?—They are frequently bought new. I am not aware but that every boiler which is in our mine at present was new when it was put there. I believe so.

1981. Do not men very often change their clothes in the boiler-house ?—It is frequently the case in many mines.

1982. Then you consider that that is tolerably safe if the boilers are in a good state ?—No, it is not considered safe at all; it is customary, perhaps; the men do not like it, generally speaking.

1983. Do you think that there is any cause for that fear ?—It has occurred that boilers have blown up, and many lives have been sacrificed in consequence. I have known it happen in the county. I was very near one, one morning, in the Polberro Consols mine, in St. Agnes, where several men were on the boiler, and one end was blown out. I do not know that either one lost his life, but several men were considerably injured.

1984. (*Mr. A. Bruce.*) How long is it since you worked in a close end ?—It is about eight or nine years since I last worked.

1985. I think you said that since that time the ventilation had been improved in the mine ?—Yes ; in the last mine, in South Caradon, two shafts have been sunk since that time.

1986. In what mine did you suffer in the way that you have described ?—In a small mine called Caradon Consols, some little distance from South and West Caradon.

1987. You say that the candles would burn dimly in those badly ventilated close ends ?—Yes.

1988. Did you ever begin to suffer from the bad air before the candle would show any sign of growing dim ?—You would suffer, of course, from the time you went into it ; you would feel a want of air.

1989. Did you or the candle show signs of feeling it ?—Yourself, especially in working, in beating the borer where it is a hard end, you would feel a want of breath; there was not a sufficient quantity of air to inhale in order to support you as it ought to do in working hard.

1990. In beating the borer you would feel those symptoms of distress much sooner in bad air than in common air ?—Yes, of course.

1991. Have you ever remarked that you were breathing in an atmosphere in which there was much dust ?—Yes.

1992. Do you think that you have been the worse for it ?—A great deal the worse for it.

1993. How soon did you feel the worse for it ?—That depends very materially, of course, upon the kind of constitution of a man ; hence I have been told by many medical gentlemen in the course of my time when I applied to them that if I had not been a man of extraordinary constitution I should have died.

1994. Did you feel it actually whilst you were at work ?—Yes, I believe that I did ; but I felt the effects of it most at the first place that I spoke of. After working in the end for some five or six months it was stopped for some time, and we commenced sinking a new engine shaft from the surface. After working there for, I think, two or three weeks, one night when I was engaged in work some bad sensation came over me, and something just like a swarm of black flies, as it were, came before my eyes, and, of course, I felt very unwell, indeed, and especially in my head, so that I had to discontinue working for some three or four weeks. I applied to a medical gentleman, and he told me that it was the effects of bad air.

1995. Did you feel immediately the effects of the dust being in the air ?—Yes ; in the time of working you would feel it.

1996. Would a man going down in a perfectly healthy state, and working in air impregnated with dust, feel at once that he was breathing dust ?—A man, without working at all, in a perfectly healthy state, if he was going into an end of that description, would feel it much worse than a man who was working in it.

1997. Would there be any marks upon your mouth of the fact that you had been breathing dusty air ?—Frequently ; in coming to the surface, frequently the nostrils and so on would be considerably furred with dust and smoke and so on.

1998. How many men were working in a close end at a time ?—Two generally.

1999. Have you known any other persons complain of the same sort of feelings as you have described ?—Yes, I knew two men who died from the effects of it, who worked in the same end that I did, my partner who worked with me died some two years afterwards.

2000. (*Mr. Kendall.*) That was in the Caradon Consols ?—Yes, one man left and went home and died from the effects of it, never having done another day's work ; I took his place.

2001. (*Mr. A. Bruce.*) The first mine that you were in was worse ventilated than the one that you worked in afterwards ?—Yes.

2002. Do you know whether it continues to have the reputation of being badly ventilated ?—It is seldom that you go into a mine but that there are more or less bad places in it, especially in large mines. Where they are driving on the course of the lode, in order to ventilate it properly, to say the least of it, at the end of every 20 fathoms a winze ought to be sunk from one level to the other, but frequently in order to spare expense it is driven much further.

2003. Be good enough to answer my question ; has this particular mine, namely, the Caradon Consols, in which you first worked now a name for being worse ventilated than other mines in the neighbourhood ?—No, it has never been worked on a large scale ; we were the only pair of men working in the mine at the time.

2004. Then do you believe that it was worse ventilated than the surrounding mines ?—I do not say that it was worse after this end came in communication with the engine shaft.

2005. But there would be constantly new ends being driven ?—Yes.

2006. And wherever new ends were being driven, therefore the same sufferings would have to be gone through by the workmen engaged in driving them ?—Yes, but it would not be driven so far before a winze would be sunk from one level to the other ; but this was an adit level taken up from the surface ; it was driven under the hill. When we first began to drive a close level, there would be perhaps only six feet in the back of the level ; at the time that it came

LISKEARD.

A Miner.

6 April 1862.

in contact with the engine shaft it was from 15 to 20 fathoms.

2007. Where are you now working ?—At Wheal Trelawny mine.

2008. Are there means of artificial ventilation provided which were not provided at the Caradon Consols ?—There are occasionally.

2009. Would those means of ventilation have been sufficient to reach such a close end as that in which you describe yourself to have worked ?—They had not the means of a waterfall in Caradon Consols ; they have in Wheal Trelawny, from the engine shaft, but there was no engine shaft in the mine at all, the only means which they had of communicating air would be sinking a small shaft upon the back of the level.

2010. Would they, therefore, have the means of preventing those sufferings in the close ends, which you describe yourself to have undergone ?—There are means ; they have the means of a waterfall now from the engine shaft.

2011. Could those means have been applied at the Caradon Consols ?—No, because there was no water ; the only means which they had of communicating air would have been by sinking a small shaft from the surface upon the back of the level which we were driving.

2012. You said that you preferred tribute work as being more healthy ?—Yes.

2013. Was that because you could choose the place in which you worked, or for what reason ?—It was because it was generally more open, better ventilated; the tutwork man is engaged frequently in driving the level, and the tributer comes behind and stopes the back of the level.

2014. Is all close end work tutwork ?—Generally the tutwork is either driving an end or sinking a winze from one level to the other.

2015. Is all driving of close ends tutwork ?—Yes.

2016. Do you think that on the whole men suffer as much in these days as they did in the days when you were working with your hands ?—Yes, to a very great extent.

2017. You think that there is no material improvement in ventilation ?—Not generally speaking.

2018. Do you think that, as a general rule, by proper ventilation the health of the miners might be improved ?—It might be greatly improved.

2019. Could you have undertaken in the mines in which you have been working, to have provided ventilation which would have prevented such sufferings as those which you have described ?—In very many cases.

2020. (*Mr. Holland.*) Did you ever work in cold-damp ?—It is generally supposed that there is a degree of cold-damp in granite mines where it is poor air.

2021. Did you feel it yourself ?—I cannot say that I did, not to distinguish it very materially.

The witness withdrew.

Mr. JOHN SAMPSON examined.

Mr. J. Sampson.

2022. (*Chairman.*) How old are you ?—Forty.

2023. You are not working underground now ?—No.

2024. What is your present occupation ?—I am inspector of the Liskeard waterworks.

2025. But you have worked as a miner ?—Yes, about 20 years.

2026. Underground?—Underground about 15 years, and about 5 years at the surface ; the first 5 years.

2027. At what age did you commence ?—About 10, but I did not go underground till about 15.

2028. What was the nature of your work ; was it tutwork or tribute work ?—Generally on tribute at the Fowey Consols for the eight years that I worked there, and at tutwork as well at the same place.

2029. What other mines did you work in ?—West Caradon and Craddock Moor.

2030. At Fowey Consols did you work in any end where the air was bad ?—Yes ; in one the end was rather bad ; at times it was worse than at other times. We worked there with a waterfall, that is, a stream of water falling through a series of pipes; and then the air is forced in by means of a fall of water through these pipes ; it is forced in through other pipes into the end. The air was very dead at the time.

2031. But means were taken for ventilation ?—Yes, a little, as far as they could under the circumstances.

2032. (*Mr. Holland.*) You mean a small trickle through a large pipe ?—The larger the stream the better the air. It is carried down in perpendicular pipes into a square box, and the other pipes are carried off from the top of the box. The end of the pipe is below the surface of the water, and then the pipe is carried on into the end, or wherever it may be.

2033. (*Chairman.*) Did you experience any bad effects in Fowey Consols ?—Yes, a little, not much. I did not work in the bad air long, only three months there.

2034. And then you took to the tribute work ?—Yes.

2035. (*Mr. Kendall.*) In what end was the bad air ?—I think it was the 40 fathoms end, driving back under Pedlar's shaft, as far as I can recollect about it ; it is a good while ago. It was a long end driving back to a shaft. I think that it was Pedlar's down-right shaft.

2036. (*Chairman.*) For what reason did you prefer tribute work?—One reason was, because it was better air, and another reason was, because I could get more money generally at it at the Fowey Consols.

2037. Why is it better air?—(*The witness produced a drawing.*) The draught is supposed to be coming down one side of these borings. This is supposed to be a shaft divided with timber, and passing up here. This is where the tributers are working, and it passes on here and up these winzes, and out at the adit level, and here the same. The air is circulating all round these places, and passing through these winzes, and out at the adit level. It is better ventilated than at tutwork. At tutwork the current of air does not come further than this, and there is no current here (*pointing to the drawing*) ; it does not reach up to these men. There is a better circulation of air in these places than in the others.

2038. (*Mr. A. Bruce.*) There is no current here (*pointing to the drawing*) because there is no draught? —No ; by-and-bye when you worked a hole through there would be a current of air.

2039. (*Chairman.*) But till they form a connexion with the winze the air is bad, unless artificial means are taken to produce it ?—Yes. This is a little fan machine, supposed to be blowing air on to these men on account of there being no ventilation. There is no circulation of air lower than that point (*pointing to the drawing*), and you get a little good air here, and it is blown in from this little machine to these men. This part is supposed to be well ventilated, and to play down as far as that, and out at the adit level. If there was no adit level there then the air would have to pass down here, and circulate not so freely as now, and pass up this side.

2040. After you left that mine in what mine did you work ?—West Caradon.

2041. What did you work at in West Caradon ?—Tutwork generally ; I commenced working on tut-work.

2042. Is that a deep mine ?—Not very ; I think I have worked at the 80 fathoms.

2043. Was there any bad end with poor air there? —Yes, there were a good many poor ends, but when

I went to work there first I did not work in the poor air, it was in a stope, so that the first place I worked in was well ventilated. The stope was on tutwork; they used to stope a good deal in West Caradon on tutwork at the first outset of the mine.

2044. Did you afterwards work in a bad end in West Caradon?—Yes, I worked in an end at the 80 fathoms which was bad, a good way off.

2045. How did you find out that it was bad?—By a difficulty in breathing, and the candle would not burn freely, and so on, and when the candle will not burn freely we find that the air must be bad; the candle is forced to be held almost flat to make it burn at all.

2046. Do you fix it in that way?—We have a knob of clay, and stick it on to the side of the level where we are working, close to the work; it is rested on any place where it is most convenient.

2047. What sensation did you experience?—Just as if there was something inside a person's head flashing, as if the head was splitting in two, every pulse that you feel it appears as if there is something inside pressing the head abroad.

2048. Were you able to work in that?—We did work for some time, but it was very bad doing it; there are always two.

2049. How long did you work in that end?—I worked there for about three years, but it was not always so bad as that; sometimes it was bad, but when we hole and have pipes, we get a good draught.

2050. How long were you working in that end?—About two years altogether in the end, and sinking winzes from one end to the other.

2051. But your health did not materially suffer then?—No, because I was young at the time; it must be nine years ago that I worked there.

2052. What was the last mine that you worked in?—Craddock Moor; I did not work there more than a month; I would not work there any longer because the ventilation was not good enough to please me; I had no family, and I would not work in bad air, except as little as I could possibly help. The air was so bad there that I would not stay there.

2053. Men who have a family are often obliged to work in a bad end?—Yes, they are forced to do so, they cannot get away very well; that is the reason. They are forced to stick there because they have no chance of getting away.

2054. Do they represent to the agents or otherwise that the air is bad?—Yes, very frequently, they tell them that the air is bad.

2055. And something is done to correct it?—Sometimes there is and sometimes not.

2056. Sometimes no attention is paid to them?—Yes.

2057. Is any reason given why no attention is paid to them?—They will tell you that it must be done, and that if you cannot do it some person else will. They say that it must be holed, and that if you cannot do it some person else will.

2058. Then you do not know from your own experience the evil effects of bad air?—I have known it only for a time. I have never felt anything since I have knocked up working.

2059. Do you know any men who have suffered from it?—My father did, there is no doubt of it; he worked underground until he was about 55, and he died at that age.

2060. (*Mr. Kendall.*) Where did he work?—At Fowey Consols.

2061. (*Chairman.*) How long is it since he died?—About 10 years, I think.

2062. What did he die of?—They call it the miner's disease, it is a difficulty of breathing; I can hardly tell what they call it; it is something like as if the heart was always beating too freely, and a difficulty of breathing, and so on, as if you had a cold. He went to two or three physicians, and he told them that he thought he was in a consumption, and all of them told him that his lungs were not in the least affected. A few months before he died he began to spit up phlegm and so on, and continued to do so until he died.

2063. Had he given up work long before he died?—He knocked off working at one time for 12 months, and then he went to work again a little while, and soon laid up again, and in a few months after he was laid up the second time he died.

2064. Have the miners any intimation before they are really affected that they are likely to suffer from working?—The only intimation I think is that they feel as if they were choked for want of breath.

2065. Is that when they are at work?—That is when they are at work and when they are not at work, both. When they get about 40 years of age or a little after that time the men feel as if their lungs were quite choked up, and they cannot draw in their breath freely.

2066. In that case do they experience any difficulty in going up the ladders?—Yes, I have no doubt that they feel a deal of difficulty. When I was working we youths used to be able to run away from the old men very easily. I believe that ladder climbing never hurt me in the least while I was working in good air, but put me in bad air, and 10 fathoms is enough for any youth to climb.

2067. Leaving a place where you had been working in bad air and then ascending the ladder, it affects you differently from what it does when you have been working in good air?—Yes, you feel as if perhaps you had been working 24 hours right out without stopping; you feel as if your head was almost splitting, and a pain right up the legs, and also in fact you feel it all over your body as soon as you begin to climb the ladders if you have been working in bad air, but if you have been working in good air you can climb the ladders just as fast as you like. Any person who is used to it can do so.

2068. But I suppose that it is not a wise thing to race up?—No, not by any means. Of course the heart will beat very hard in going up the ladder fast.

2069. In the Fowey Consols is there any dry?—We used then to dry our clothes at the blacksmith's shop, that was some 16 years ago, I cannot tell anything about that now.

2070. Did the men catch cold?—Yes, I believe that the men caught cold by sitting in the footways more than anything else. That is tutwork men, the tributers would also catch cold, because they had miserable places to change in at Fowey Consols while I was there, they had miserable little barracks. I do not know whether it has been altered since I came away.

2071. But it is desirable that there should be a warm place?—Yes, I should think so; that it would be a good deal better for men if, instead of sticking about in the footway, they could get up and have a warm comfortable place to change their clothes in.

2072. But why are they standing in the footway?—If they come above and meet the captain at the head, and should happen to be up before time, the captain will spale them 2*s.* 6*d.*

2073. Before the eight hours have expired?—Yes; they have these places down here, they will perhaps blast a hole or two, and they cannot get there again; they will perhaps do this by 9 o'clock, they will expect to get up about 10 o'clock, and they will be there perhaps half an hour or sometimes three-quarters of an hour sticking there waiting for the bell to ring, and as soon as the bell rings they will go up and change, but before they can get up, they are perhaps stiff with the cold; they get entirely chilled by sitting there so long.

2074. That is their own doing?—Yes; but in my opinion it might be prevented if the captains would allow them to come up; they keep them in the mine instead of letting them come up, and giving them a nice clean room to change in.

2075. But why are they detained?—Because they oftentimes commence to leave their work before they ought to leave it.

LISKEARD.

Mr. J. Sampson.

16 April 1862.

2076. But tutwork is by piecework?—Yes, all by piecework.

2077. How many holes can two men bore, do you suppose, in the eight hours?—About three or four; it is according to the ground, some ground bores harder than others.

2078. Take granite?—About three holes, about two feet deep, would be just enough.

2079. That is supposing the air to be good?—That is supposing the air to be pretty good; if it is bad air they would do as much perhaps if they had the advantage to do it, but sometimes in an end they have not the advantage to bore three holes together. They must blast before they can bore the second, and then if they are forced to go in and bore one hole, and blast that hole before they can bore two more, it will require perhaps more than their eight hours; but if they could bore and blast the three holes together, they might then go up, because they would then have done their work, and they would have no more that they could do for two or three hours.

2080. Although it was bad air you think that they could bore as many as three holes in an end?—Yes, they might bore three holes in an end against the eight hours were expired, but not if they had to shoot them singly.

2081. (*Mr. Kendall.*) Do they frequently bore three holes?—Yes, sometimes they will, if they can get the advantage to bore three holes.

2082. Taking the average, do you think that two holes are bored once out of 20 times together before blasting?—Yes, in bad air ends more than that; I always used to calculate to bore as many holes as we could.

2083. I understand from you that if there were comfortable drying houses at the surfaces the men might not be kept at the footways so long?—Yes.

2084. How would you manage about the time?—They would not attempt to come up every day before time, unless they had done their hour's work. The men would come up into this comfortable room and sit down, and the captain should come and see that they were all there; and if they should happen to be up ten minutes before time, they might change comfortably.

2085. Why should that affect their leaving the work before time?—They have no watch, and cannot tell what time to leave.

2086. How will a comfortable dry affect that?—Instead of standing in the footways they would come up and sit in the drying house.

2087. (*Chairman.*) But they would be fined all the same, would they not?—No; the captain should not fine them, but they should be allowed to stay there.

2088. Is there nobody below to whom they could communicate as to whether, when they had blasted, they might have permission to leave their work, as they could not go back to it?—No; there is no person nearer than the counting-house.

2089. So that if a man has set off two shots and fired his hole half an hour before his time is up, he must still wait in the mine, although he cannot work?—Yes.

2090. Supposing that the time was nearly up, would the men who were at tut-work wait till the others came down to relieve them?—They will get as near the surface as they can, because if they are far down in the mine it will take them a much longer time to come up, and instead of eight hours they will have had nine. If the men were coming down, those men coming down would fill the ladders, so that the men already underground would not have a chance of getting to the ladders till all those men were down.

2091. Therefore it is the object of the men to get up to the top of the ladder before the new set are coming down?—Yes, in order that they may not be kept waiting.

2092. (*Mr. Kendall.*) Do you think that in any of the large mines it frequently occurs that men are waiting there?—Yes, I believe it to be so in every mine in Cornwall; in every place that I have worked at I have found it so.

2093. (*Chairman.*) Do not men sometimes catch cold even below by standing?—Yes, by standing in these draughty places they might catch cold, not quite so quickly as at the footways, but they catch cold by standing there as well as in other places.

2094. Are there no means taken to give notice down below in the mine when the time is nearly up?—No means in the world that I have ever seen.

2095. Could not that be done?—It would be a difficult matter in an extensive mine, I have no doubt.

2096. (*Mr. Kendall.*) Do not the agents of the mines generally go down almost every day?—Yes.

2097. And as they are passing through the mines just before they go up, is not the captain supposed to know the time, does he take his watch with him or not?—I never saw the captain or anybody else with a watch underground. In South Caradon I heard a man say that Captain May would throw a stone and break a man's watch if he took it underground, because he said they should wait for relief, but it is not always the case that there are six men.

2098. (*Chairman.*) Are the orders in mines that the men should not leave their tut-work till they are relieved?—I believe they are, all of them, required to work eight hours, but there are other cases where there is no relief to come.

2099. Are they to remain at their work till the relief comes? is that the condition upon which they undertake tut-work?—They are supposed to do so when they are working six men, but not if there are only four men. These men may be hundreds of fathoms down, and they know nothing about the time. If the afternoon corps men get up five minutes before the time, I have known them spaled 2*s.* 6*d.*

2100. Do the captains visit each set once a-day, or how often?—Sometimes once or twice a week, it is according to the part of the mine.

2101. At what time do the captains generally come up?—About two o'clock generally.

2102. Before the men come up?—Yes.

2103. (*Mr. Kendall.*) Are there not many surface captains looking about to send men down to their places, so as to be in time?—I believe that the surface captains have nothing to do with the underground men regarding relief. A captain comes out with every corps to see that the men go down at the proper time.

2104. Is it not the system that the agent every now and then looks about to see that parties do go down in time to relieve those corps?—Yes, I believe that that is the usual system, but what I am speaking of is of four men, where there is no chance of any relief coming.

2105. (*Mr. Austin Bruce.*) I suppose that it may be taken as a general rule that all tribute work is done in well-ventilated parts of the mine?—As a general rule it is so, because these levels and winzes and things are driven and sunk first, before the tributers come on, as a general rule.

2106. Have you ever worked at tribute work in bad air?—Yes, sometimes in high backs before it is holed at all, it is carried up in a single piece and closed up at the ends; it is sometimes bad at first, but it extends as they get up.

2107. Are any means taken there to improve the natural ventilation?—Sometimes the men themselves will put a trap-door in the level so as to cause a draught to play up in the back as much as they possibly can.

2108. You have done a good deal of tut-work too, have you not?—Yes.

2109. As a general rule, was the ventilation there good or bad?—Bad generally.

2110. Supposing that you were to divide your working life into two periods, how much of it did you work at tribute work, and how much of it at tut-work?—I should think, perhaps, about half of each.

2111. During the time that you worked at tut-work,

how much of your time was spent in bad air ?—I should think not more than 12 months altogether.

2112. Out of how many years ?—Seven and a half years.

2113. Do you believe that that is about the usual proportion of time which miners spend in bad air ?—No ; many will spend a good deal more than that in bad air, I would not do it.

2114. Then you attribute your having spent less than the ordinary time in bad air, to the fact that you were able to choose your work ?—Yes, I was able to choose my work more than a great many men were.

2115. Do you think that that 12 months has had any permanent bad effect upon your health ?—I do not know, I have not felt anything since I have not been working underground.

2116. What was the longest time that you ever worked together in bad air ?—About three months.

2117. How did you feel at the end of that three months ?—I felt as if I failed a good deal in the time, I know that I failed a good deal in the time ; I felt weak and sleepy, and stupid, and almost always had a headache, a sick headache.

2118. Did you take any holiday at the end of that three months ?—No.

2119. What did you do ?—I still continued on at the work, because we had a better air place afterwards.

2120. Did you recover while at work ?—Yes, afterwards.

2121. How long were you before you got back to your usual state of health ?—I did not take any notice of that, I cannot tell, perhaps, it might have been about two or three months before I got back again. Such things we do not take a great deal of notice of, generally.

2122. (*Mr. Holland.*) Was this throbbing at the head, which you have spoken of; the first symptom which you had of bad air ?—Yes, a splitting headache is the first thing, and then you feel it in the limbs. As soon as you take any exertion you feel like one terribly fatigued.

2123. The knees failing under you ?—Yes, everything. If you try to do anything you feel as if you were uncommonly fatigued, as if you were almost worn out with fatigue.

2124. You wonder what has tired you so much ?—Yes.

2125. You talked of working three months in very bad air ; do you mean in such bad air that a candle would not burn without being sloped ?—Yes, the greater part of the time a candle would burn scarcely at all, and at the latter end when we were close upon holing, the candle would go out more than 50 times a day, and we had to keep lighting it with a match, and to keep it almost flat to make it burn at all, and to keep picking it with a pin. We could not stand longer than shooting two holes, and had then to go away or our head would be splitting. It was in West Caradon, in sinking a winze 50 or 60 fathoms away from another winze, before holing it was very bad. If they are rising at any place they call it holing or making a hole through.

2126. Could you work for eight hours together in such air as that the candle went out ?—No.

2127. How long did you work there ?—As long as we could, perhaps five or six hours.

2128. Did you work six hours together ?—Yes, they generally stayed down for that time, they would come out of the bad air for a little time, and then return.

2129. How long could you work together in that very bad air ?—Perhaps an hour, that would be quite enough. Then we should come up on the level, and sit down and have a little fresh air.

2130. How long was it before you returned ?—Perhaps half-an-hour, the air would get fresh in the bottom and then we should go down again.

2131. In fact you would only work about two-thirds of your time ?—Yes.

2132. And then you would not work so hard ?—No.

2133. You would lose about half your work ?—Yes.

2134. Were you not paid more per fathom for that work ?—Yes.

2135. How much more ?—We are generally paid according to the measurement.

2136. If you take your bargain in bad air, do you not make an allowance for it ?—Yes, if the ground could not be driven or sunk for 5*l.* a fathom, they would give 10*l.* if it required it.

2137. If the air was good you could do it for 3*l.*—Yes.

2138. And make more money yourselves ?—Yes.

2139. (*Mr. Davey.*) Were there many places in West Caradon similar to what you have spoken of ?—Yes ; there were a good many places where there was bad air at times, and it is so in almost every mine ; they can hardly help it. There are a good many places which might be better ventilated than they are.

2140. Were there many such places at the same time as you were there ?—I cannot tell you, because when we are working in a certain district we do not visit other places generally. Miners take offence at other miners going to their ends ; they generally get a little way out of the end, and sit down and have a chat.

2141. (*Mr. Austin Bruce.*) Does every miner in your opinion have his turn at bad air ?—There are some, I suppose, who have scarcely ever worked in any bad air in their lives, but as a general rule I suppose that the greatest part of them have had a little, some more than others.

2142. How do some manage to escape bad air altogether ?—By their working on tribute they will generally escape the greatest part of it, but if not they are almost sure to have some ; I have escaped bad air myself before now.

2143. How many men were working in the whole mine of which you speak ?—I cannot tell that ; perhaps 400 or 500 men, I should think, at the time.

2144. Did the men who worked with you suffer in the same way as you did ?—Yes, exactly the same.

2145. Could you judge by your eye that they were suffering ?—I think not, because miners generally look delicate, and if they are working in bad air it will tell upon them in a little while, but you cannot tell it by looking at them.

2146. Did any of the men who worked with you fall permanently ill ?—No.

2147. They recovered when they got into better air ?—Yes, because they were all young men ; I believe that I was nearly the oldest of the four ; one called Morris was with us ; whether he was a little older than I was I do not know, but not much.

2148. Have you ever worked in a place to which in your opinion good air might not with proper arrangements have been brought ?—I have worked in ends before now where good air might have been brought if they had taken pains to do it.

2149. But have you ever worked in any to which air could not have been brought ?—No ; it might be always brought by artificial means, if it could not be any other means.

2150. Would those artificial means have been so expensive as to be altogether unreasonable ?—No ; it would cost about 25*s.* a month for a boy to blow a small fan machine just to blow in air to a couple of men, besides the expense of the machine, but I think that there are better means.

2151. In driving those close ends you made your bargain as to the rate at which you were working, I suppose ?—Yes, so much per fathom.

2152. In making that bargain, did you take into consideration the quality of the air in which you were likely to be working ?—Yes.

2153. Did you consider that you could do so much more in good air than in bad ?—Yes.

2154. Would you, therefore, have asked a higher price for work done in bad air than in good air ?—Yes.

2155. Did you actually consider those circumstances

LISKEARD.

Mr. J. Sampson.

16 April 1862.

yourself when you made your bargain ?—Yes ; the circumstances of poor air.

2156. In your opinion in those cases in which you worked in bad air, would the lower price which you would have taken, had the air been good, have made up to the masters for the expense of providing sufficient ventilation ?—In some instances it would, and in others it would not. When you get a great distance off, the expense, perhaps, would be more to put in means to get air than you would save in the price.

2157. Then, supposing ventilation had been supplied in those cases, the masters would have been under some temporary loss as long as that end was being driven ?—Yes, there is no doubt of that.

2158. Have you studied the ventilation of different shafts ?—Yes.

2159. Do you see at some shafts means used which are not used at others ?—Yes, it is very frequently the case.

2160. Where they might be used ?—Yes.

2161. Equally in all ?—Not equally in all, but the greatest of them might be used. I think that the air soller is one of the best things which was ever invented. This is supposed to be a level 10 feet high, instead of seven (*pointing to the drawing*), and these pieces of wood are put in across the level to take the tramroad or railroad ; it is covered with boards ; it is sollered over with boards.

2162. (*Mr. Holland.*) So as to make a floor ?—Yes. There is a space between that and the bottom of two or three feet. The air will play under the soller close to the end, back over, and take its regular course again.

2163. (*Mr. Austin Bruce.*) An artificial draught is created by those means ?—No, it is not an artificial draught ; it is a regular draught coming down the shaft. It is driven in there, instead of being carried up there (*pointing to the drawing*).

2164. It is, therefore, artificial ?—You may call this an artificial draught altogether if you like.

2165. But for making that soller you would not have the same supply of air ?—No ; it is an artificial level, not an artificial draught.

2166. (*Mr. Holland.*) It is an artificial channel for the draught ?—Yes.

2167. (*Mr. Kendall.*) Take a granite end at about 8*l.* a fathom, if you had to sink holes, how many holes would you bore where the air was very dead ?—Two are just enough.

2168. Are not two a good deal ?—No, they might bore two holes if the air is dead, but not what they call bad.

2169. Take bad air ?—In bad air, two holes would be a hard day's work.

2170. (*Chairman.*) But they could do it ?—Yes, they might do so, but they would soon kill themselves if the air is actually bad.

2171. Suppose that it is from smoke ?—The smoke does not injure any person half so much as the deadness of the air, if there is no current of air.

2172. When the smoke does not get away, how many holes can you bore ?—Two would be just enough if the smoke would not clear away quick enough.

2173. Do you suppose that nobody has ever bored more than two?—Yes, they bore four sometimes ; I have done so myself, but it must not be in a bad air end.

2174. (*Mr. Davey.*) Supposing that the end was 100 fathoms from the mouth of the adit without any artificial means of throwing in air, how many holes could they bore ?—I should think that one would be enough there.

2175. (*Mr. Kendall.*) When you got ill, did you get into the doctor's hands or not ?—Yes, just to have an emetic and a few things to get the stuff out of my stomach, that was all.

2176. Then you went into better air ?—Yes.

2177. And that was the best medicine which you could have ?—Yes.

2178. Have you been in the doctor's hands at all since you have left off mining ?—No.

2179. Are you a strong man ?—Yes, quite strong, I believe that I have never taken a dose of medicine since I have been out of the mining.

2180. You can do as good a day's work as the next man now, I suppose ?—Yes ; and I am in very good health, and am quite lively.

2181. Was your father a miner ?—Yes ; all his lifetime.

2182. He died young ?—At 55.

2183. Were any of your brothers miners ?—I have one a miner now.

2184. How old is he ?—He is about 20 or 21, I think, now ; he lives at St. Cleer.

2185. Is he working in bad air now ?—Yes ; he looks so now.

2186. (*Chairman*). Where ?—At Craddock Moor. That is a very badly ventilated mine, I have no doubt of it ; it was so when I was there, and they tell me that they have sunk a shaft down to 40 fathoms since ; all below that is bad air.

2187. And are there no artificial means for ventilating it ?—I do not know anything about that, I have not been there ; in mines it is the old air passing round and round so many times that it becomes impure.

2188. (*Mr. Kendall*). As far as the agents are concerned, have you ever made any complaints to them about bad air ?—Yes, I have myself asked for timber to put in air sollers, and was not allowed to have it. I have asked agents about it, and they would not allow us to have timber ; they said, " It is " not worth doing." In the end that I speak of, in the 80 fathoms level in West Caradon, we put in air sollers unknown to the captains.

2189. Where did you get the wood ?—Where we could catch it.

2190. (*Chairman.*) You were refused permission to have it ?—Yes, we were refused timber, and I believe that we drove that end cheaper than any person else did before or afterwards ; and we could do it, because we could be in that end and shoot four holes, whereas formerly they could only do two. I think that the air soller is as good a thing as could be adopted for the ventilation of mines.

2191. (*Mr. Austin Bruce.*) Do you say that your brother is now working in a mine ?—Yes.

2192. And that it is badly ventilated ?—Yes, the men tell me so ; I cannot give evidence upon it.

2193. (*Mr. Kendall.*) I suppose that when you could afford it you went to tribute, and when you could not afford it you went to tut-work ?—Yes, we could not get much on tut-work.

2194. And I suppose that that is the case throughout the whole mining population ?—Yes ; they will go to tribute if they possibly can, because tut-work wages are so low. If they can get credit from the shopkeeper they will go and live upon the poor shopkeeper, and he is obliged to suffer.

2195. (*Chairman.*) How long is the tribute man without getting anything, and subsisting on sist ?—Sometimes two months.

2196. What do they allow him for sist during that time ?—In some mines more than others. In some they allow about 20*s.* a month, and in some 40*s.* At West Caradon they used to allow 40*s.*, but I have heard that they only allow 20*s.* now on sist.

2197. (*Mr. Davey.*) You do not go on 12 months without a settlement ?—No ; they have a debt bill given them ; they are perhaps 3*l.* or 4*l.* in debt at the end of the month.

2198. (*Chairman.*) It is a settlement on the wrong side ?—Yes.

2199. (*Mr. Kendall.*) Sometimes it is otherwise ?—Yes ; sometimes they get 50*l.* or 100*l.*, or 120*l.* If they should have a high tribute and get a good supply of ore, they might have a good start.

The witness withdrew.

Mr. Peter Clymo examined.

2200. (*Chairman.*) I believe that you are a considerable proprietor of the South Caradon mine ?—Yes.

2201. You are the principal manager there ?—Yes.

2202. Is that mine a copper or a tin mine ?—Copper.

2203. Do you manage other mines?—I am the manager of Mary Ann mine, a lead mine.

2204. How long has the South Caradon mine been in existence ?—We began in 1836.

2205. I believe that you discovered it ; you were there from the commencement of it ?—Yes.

2206. How many men have you in the South Caradon mine underground ?—Underground we have now upwards of 400. I have not counted them particularly.

2207. And how many women and children above ground ?—Upwards of 200, I should say.

2208. Have you any boys employed underground ?—Yes.

2209. At what age do you allow them to go down underground ? Have you any fixed age ?—No ; they go down generally about 12, 13, or 14, generally with their fathers.

2210. What is the nature of the work in which the women are employed ?—The women are employed in separating the ores.

2211. And at the South Caradon mine they work under cover ?—Yes, principally.

2212. You think that that is an advantage and comfort ?—Yes, it is a great comfort, both in winter time and in wet weather.

2213. What wages can women earn ?—They get 1*s.* a day ; those are their regular wages.

2214. Have they any deductions ?—Twopence a month for the doctor.

2215. Are there young girls and young boys employed ?—Yes, at almost all ages, from 7 or 8, I suppose, upwards.

2216. They are also employed in picking ?—In separating the ores, but they get different wages. It is the elder girls who get 1*s.* a day.

2217. Do the underground men work with you at both tribute and tut-work ?—Both.

2218. They have a changing house, I think ?—Yes.

2219. Do you think that that is a very great comfort to the men ?—A very great comfort.

2220. It is appreciated by them ?—Very much.

2221. Do you think that it is calculated to be an advantage to their health ?—There is no question about it.

2222. Will you describe it ?—What they have now is very different from what they used to have many years ago ; there was nothing of the kind ; there was no dry or anything of the sort ; there was a house in which the men used to change, and there was no fire, or anything of the kind ; and, in fact, in many places there were not even windows. I have seen myself many times a long house where there were places for windows, but not even a window or a door hung, so that a strong wind must be going through ; but now, in mines of any magnitude, the whole of them have dries, whereby the men's underground clothes are dried, and made comfortable for them against they come to their different corps; and also, if they should happen to get wet in going to the mine, their walking clothes are dried for them against they come up.

2223. Are the clothes which they come in, if they get wet, ever dried ?—Yes.

2224. To your knowledge are there many as good drying houses as the one which you have put up at South Caradon ?—There are drying houses, but I do not know whether they are generally so good.

2225. You have also, I believe, warm water for them to wash in ?—We have. It is condensing water brought from the engine, and it is close by the dry.

2226. The dry is sufficient accommodation for the 400 men ?—Yes ; we have two there.

2227. About what was the cost of putting up that dry ?—I should say that in the largest which we have put up there, the last one, the slate and altogether was expensive, and I should think that it cost 100*l.*

2228. But you think that for the comfort of the men it is money well expended ?—There is no doubt about it.

2229. Is it within your knowledge that there are places, such as you described just now, without windows and without any heating apparatus ?—I do not know at present ; but I am speaking of years gone by.

2230. Do the miners employed in your mine ever engage in any other work besides that of the mine ?—Not that I am aware of.

2231. I suppose that they have many of them gardens at their own homes ?—Yes, most of them, that is to say, the married men.

2232. Your miners commence work, I suppose, at the same hours as in the other mines ; there are three corps ?—Yes ; that is to say, the tut-work men they come at six in the morning, and two in the afternoon and ten at night.

2233. Have the tribute men any special hours ?—Not particularly ; they come perhaps about half-past six or seven in the morning ; then they take their own time. If they are doing pretty well, you will find that they will work perhaps till nine or ten at night ; but if they are not earning more than just their regular wages, if they are earning perhaps about 1*l.* a week, they will come up at three, four, or five in the afternoon.

2234. I suppose that in some cases the tribute men do not earn anything for some time ?—Sometimes ; there are a great many of them ; they are like the adventurers in a mine, they speculate on tribute, they take a piece of ground which has been lying idle perhaps for years sometimes.

2235. Do you think that the tribute system is a good system for the proprietors of mines ?—I think so ; a great deal of ground is worked in that manner which would not otherwise be worked. For instance, we have perhaps a piece of ground 50 fathoms long that has been lying idle for years, and nothing is done in it, and then a pair of men have been searching ground, and they come to this place, and perhaps find a kindly little piece, and they say that they will try a pitch, and they take it of the agent. They frequently rise up a fathom or two, and find a bunch of ore in that piece of ground, and that ore would never have been discovered but for the tributers.

2236. How much have you ever known in that way at a rough guess to be the result of this tribute work ?—Many thousands of pounds worth.

2237. Discovered in that way ?—Entirely in that way. We have given 13*s.* 4*d.* in the pound for every pound's worth of ore, two-thirds. Then after the men have worked there two months, perhaps that pitch will let sometimes for 2*s.* 6*d.* or 5*s.* in the pound ; it depends upon the richness, of course.

2238. You say two months, I thought that the tribute work was let for one month ?—One month or two months if they like ; the tributers have the option of going on a second month if they think proper. If they wish to give up at the end of a month, they come in and give the agent notice the Wednesday before the month is out.

2239. At the end of the two months the ground is reset ?—Yes ; the agents go down again then, and fix a new tribute on the piece of ground.

2240. Will you state to the Commission the manner in which this is managed on the settling day?—There are certain limits. A piece of ground may be 10, 15, or 20 fathoms long, which is let so many fathoms east or west from a certain winze. That piece of ground is let to a certain number of men, and the agents go down and calculate the number of tons

which they think those men can break in a month, and what they think the one will be worth per ton. That will amount to so much money ; then their cost is so much ; they see in a moment what their cost is ; they add the labour to it, say 8*l.*, if there are two men, and they see what tribute those men ought to have in order to earn that amount so as to pay the cost of the wages. We generally calculate the tributers to earn a pound a week.

2241. I suppose that where the tributers work in most mines it is naturally better ventilated than where the tut-work men work ?—Yes, because where tributers are working, generally speaking, the level has been driven through and winzes are sunk, so that they are working between two draughts, between two winzes.

2242. What means of ventilation do you employ for ventilating a close end ?—We sink winzes occasionally, sometimes, perhaps, every 20 fathoms ; we sink winzes from one level to the other, and particularly when we have copper, or tin, or lead, or whatever it may be, to sink on. But supposing that there is not copper, tin, or lead to sink on, we sometimes drive further ; then we put in an air machine, we have several air machines in our mine, what we call fan machines, which blow a very beautiful stream of air into the end.

2243. Worked by a boy ?—Yes.

2244. What is the cost of the boy ?—Each boy gets about 15*s.* or 16*s.* a month.

2245. What would be the cost of the machine itself ?—That is trifling ; a pound or two perhaps.

2246. There is no reason why it should not be used ?—No reason whatever ; in fact it will be a great loss to the adventurers if they do not use it, because the men can do so much more work.

2247. Where that machine is placed there must be a good current of air ?—Yes ; it is always put where there is a good current of air. In some places there may be a winze back so many fathoms, through which there is a great draught which is not wanted, and then we cover over that winze ; we always endeavour to have our machine where there is a good current of air.

2248. Do you ever divide a level for the purpose of making a current, as you would a shaft ; what is called in coal mines bratticing ?—No, it has been done, but I have not seen such a thing for many years. I have seen, many years gone by, what we call air sollers put at the bottom of the level. You have to walk over them, and put your barrows and everything over them.

2249. Does that answer ?—It used to answer, but nothing like so well as the machines.

2250. You would have to drive the height of the level higher ?—Yes, and not only that, but in those days there used not to be railroads, it was all wheeled by barrows, and walking over those sollers you could hardly ever keep them air-tight.

2251. But that would not be the case if you could lay rails on them ?—No, it would no doubt be better, but it is very little used now ; I have not seen such a thing for years.

2252. But you have never seen a level divided by canvas or otherwise ?—No.

2253. You have never seen the same principle carried out in a level as is carried out in a shaft by dividing it ?—No.

2254. In a shaft so divided there is a down-cast and an up-cast current ?—Yes.

2255. Does that draught vary according to the weather ?—Yes, sometimes if you are sinking a shaft, even from the surface, in very hot weather there is no draught, and you are obliged to throw in water and lime and all sorts of things in order to break the damp. There is a sort of damp which stands, you can see it like a cloud below a certain place on looking down the shaft, and many times water or hot lime has been obliged to be thrown down in order to break it.

2256. That is in sinking the shaft ?—Yes.

2257. Are the men working below then ?—Not if the air is very bad, they do not attempt to do so. That is the reason why they sometimes throw down this water or lime or so on, in order to break the damp, and then the air plays down and the men are then able to work.

2258. Do you use steel boring tools ?—Yes.

2259. That is a great advantage to the men ?—I have no doubt it is on the whole, I think it is the cheapest for the adventurers, the men can do more work with it.

2260. Those tools do not require sharpening so often ?—They do not.

2261. Then that is a saving to the men ?—It is a saving to the men and also to the adventurers, unquestionably, particularly in hard ground.

2262. Have your men any set of rules given them with regard to blasting, and their conduct down in the mine ?—No particular rule. It is all done with the safety fuse, it used to be done with a large nail, but that is hardly ever used now.

2263. Then any accident happening from blasting must be the fault of the men ?—I believe that a good deal of it is that.

2264. But there is a certain danger nevertheless in blasting ?—There must be some, particularly if the men are not very careful in what they put into the hole for tamping ; they should be very careful in selecting the stuff for tamping, that is in filling up the hole upon the charge. But I am sorry to say, that many of them are not sufficiently particular in that respect, the men take anything for that purpose, being in a hurry to got their work done ; but that is a very important thing, and they ought to be very careful about it, they are frequently cautioned about being very particular in that respect.

2265. With regard to the men who are working at tut-work when the eight hours have expired, is the agreement with them that they are to remain at their work till the other men come to relieve them ?—It is not always the case. Sometimes when you want to push on a certain place you oblige the men to relieve in place, so that those who are down must not leave till the others come to relieve them ; but that is not always the case. Perhaps, two-thirds of our men meet in the ladder road, when the bell rings the men at the surface go down and meet the others coming up.

2266. Which body of men gives way to the other if they meet in coming up and down ?—I do not know that there is any particular rule for that, when they get to the bottom of a ladder they stop and let the others pass.

2267. The men leaving their work, I suppose, are anxious to get to the surface ?—Yes, sometimes they climb too fast, and that, no doubt, does them an injury.

2268. Do they come up before their time ?—Very seldom ; I believe if they are found to come up before their time and the agents see them, they will have a fine.

2269. Have they any means of knowing what the time is below ?—Scores of them carry watches underground.

2270. In your mine ?—Yes, but they do not want it ; they can tell as nearly as possible by their candles. A candle is calculated to burn so long, and they can tell very nearly.

2271. I suppose that there is a great difference in the composition of the candles ?—Yes.

2272. I suppose that you contract for the candles with which you supply the men ?—That is the case sometimes, but we do not do so ; we order our candles from different parties as we want them, and if any man sends a bad article we do not give him an order the next time.

2273. But I suppose that in many mines they contract for their candles ?—Yes, sometimes they contract for six or twelve months.

2274. And then they are sometimes bad ?—The contractors will try sometimes to send in bad articles without great caution.

2275. I suppose that a bad candle is injurious to

the miner ?—Yes, particularly in a close place, there is a very bad smell with some of them.

2276. I believe that in your mine the men ascend by ladders ?—Yes.

2277. Have you not a footway out at the side ?—Yes; they come up to the adit, and then walk out through the adit.

2278. What height of ladder have your men to climb in the South Caradon mine ?—Our deepest part is 140 fathoms under the adit.

2279. And when they get to the adit they walk out ?—Yes.

2280. Do they ever fall away from the ladders ?—It is the case sometimes, but not very often.

2281. By what is that occasioned—by carelessness ?—I cannot tell. They sometimes carry a pick down in their hands, and then if a man has not pretty long fingers he has not much hold upon the ladder-stay, and they slip in that way.

2282. Are the ladders inspected ?—Yes. We have what we call a timber manager with us, and a pitman, who always examine the ladders; they are going down every day, and they would see if there is anything amiss directly.

2283. I suppose that the men never go down in skips in any mine that you are acquainted with ?—Not here.

2284. Have you ever seen the man engine at work ?—Yes.

2285. Do you think that that is a good invention for some mines ?—I have no doubt that it is a very good thing, particularly when you have a deep mine. A great deal depends upon whether you have more than one lode. If you have but one lode, and all your men are working, for instance, within say 200 or 300 fathoms, then a man engine, no doubt, is a very good thing if you have a particular shaft that you can spare for it. But take our mine. We are raising our ore from 12 different lodes; those lodes are hundreds and hundreds of fathoms apart. There is a pit north and south from the different lodes, and then east and west from there; so that if we had a machine in one part of our mine, not more than a quarter part of the men would get up by it, because they could get up sooner from the other places by the footways.

2286. If there was a man engine, do you think that a man would travel any distance to it rather than climb the ladder ?—If it was within a reasonable distance, no doubt he would prefer the machine, but he would not travel a great distance to it.

2287. In a bad end is it shown to be bad by the candle not burning; is that how the men judge ?—Yes; the candle will tell you the first thing, before the men can feel it.

2288. Would the men then report to the captain that the candle would not burn ?—They come whenever there is anything of that sort; but the captains discover it themselves, and then they have a machine put in; but if they should not happen to discover it, the men are sure to tell them of it.

2289. In a well-regulated mine the complaints of the men are immediately attended to ?—Yes.

2290. What is the greatest heat in your mine ?—It is a cool mine, generally speaking; the granite is generally much cooler than the killis or slate.

2291. (*Mr. Kendall.*) Prior to your coming to South Caradon you had very large experience, had you not ?—I was at Fowey Consols for many years.

2292. And you had also this advantage, that your father was one of the most experienced miners in the county of Cornwall ?—Yes, he did nothing else all his days.

2293. Did your father ever work underground as a miner ?—Yes, he worked underground as a miner a good many years after I can recollect.

2294. Did you ever work underground yourself also ?—Yes.

2295. Before you were of age ?—Yes; I worked underground till I was 23 years of age. I never did anything else, in fact.

2296. You have gone from the very bottom up to the top of the tree ?—Yes.

2297. You have worked your way up ?—Yes.

2298. You were also one of the managers of Fowey Consols mine ?—Yes.

2299. When you were there, do you recollect what were the returns of that mine; were they larger than the returns of almost any mine in the county ?—Yes, they were very large indeed. We had sometimes 300 or 400 tons a week.

2300. It was supposed to be one of the most extensive and best worked mines in the county, was it not ?—Yes, it always had that name.

2301. What was the ventilation in that mine ?—Generally speaking, pretty well; we had a good many shafts there. The worst places that we had at all there I suppose were in the cross cuts, because you cannot sink winzes there, having no level over.

2302. Had you many forcing machines there for the air ?—Yes, a great many.

2303. But still there were several bad ends there ?—Yes, there were some bad ends.

2304. After you came here, and you made the discovery yourself of South Caradon, you took from your brother the management of that mine ?—After my brother's decease.

2305. And you and he together inspected that mine a good deal ?—Yes, I went there frequently before I came here to reside.

2306. After you came here to reside you went underground frequently yourself ?—Yes.

2307. You paid great attention to it ?—Yes.

2308. Have you given great attention to ventilation at the Caradon mines ?—We have.

2309. Have you been very careful in selecting your agents since you ceased to go underground ?—Yes, we always select men that we can depend on.

2310. South Caradon was the first discovery ?—It was the first discovery in this neighbourhood.

2311. (*Chairman.*) Are East and West Caradon yours ?—No.

2312. (*Mr. Kendall.*) Did you ever know a case where there was bad air, and where men complained of bad air, and asked for some means of curing it, and it was refused by the agents ?—Never. I never heard of such a thing.

2313. You have bad ends at South Caradon even now ?—I am not aware that we have. Of course when you get in a certain distance from a winze the place will naturally get close.

2314. Prior to putting in the air pumps the air of course gets a little dead, and then you remedy it ?—Yes; we then put in a machine directly for drawing the air, and where we have long distances we have at different times ordered zinc pipes on purpose, because a wooden pipe will destroy the air a good deal more than zinc; the zinc pipes convey a great deal better air than the wooden pipes would.

The following extract from the evidence of a Miner was read to the witness :—

"(*Mr. Kendall.*) Did you know any place in South
" Caradon while you were there where, at a mode-
" rate expense, they might have forced in air, and
" did not do it ?—Yes, in the last mine that I worked
" in.

" (*Chairman.*) Was that South Caradon ?—Yes.

" (*Mr. Kendall.*) That was not where you first
" worked ?—No, that was the Caradon Consols.

" What end did you last work in ?—The 120
" fathoms level.

" How far were you then in beyond any communi-
" cation with the air ?—We were in, perhaps, 40 fa-
" thoms from the shaft; and there was an angle in
" the level, and we had to drive on the cross course
" to intersect the lode, and it was a timber level; we
" had to put in timber into that level, and that makes
" the air so much the worse.

" Then were you in 40 fathoms before you had
" an angle ?—No, not 40 fathoms before the angle,

" but, perhaps, 15 fathoms from the shaft before the " angle.

" And how many fathoms after the angle ?—25 " fathoms.

" How far was it before you made any communi- " cation ?—At that distance they cut a lode and then " sank a winze on the lode to the cross level.

" In sinking that winze the communication was " still only through this drift ?—Yes.

" Was the air bad in that winze ?—Yes.

" How many men were working in that winze ?— " Four.

" You had eight hours' rest ?—Yes.

" After you had rested was there a perceptible " difference in the air ?—Yes, there was a very great " difference in the morning.

" A supply had come in ?—There was a better " supply. There was not the same foul smell. The " candles are generally not of the best kind, the wick " of the candle is frequently made of hempy stuff " when it ought to be of the best cotton. We fre- " quently consider that the candle smoke does us as " much or more hurt than the powder smoke.

" Before you communicated the air was very in- " ferior ?—Yes.

" How long was it after you began to work before " you found the candle show a difference ?—Not very " long, two or three hours perhaps, and even in the " first commencement it would not burn so clearly as " in the good air parts.

" You were obliged to blast in the sinking ?—Yes.

" How long was it before the smoke got out ?— " It would never get out at all while we continued " working ; before the smoke of one hole was gone, " or, as we term it, had died away in the place, we had " to blast another, so that in these poor places we " were constantly working in smoke, either more or " less.

" Might the agents at a small expense have sup- " plied you with better air ?—Yes, they might have " put in a waterfall from the engine shaft.

" Was any remonstrance ever made to them ?— " Frequently.

" And what did they say ?—The reply is, 'If you " 'do not like it you must leave it.'"

2315. Do you believe that that is correct ?—I do not.

2316. Do you think that in any mine of fair working, and where there is fair judgment, they would allow a thing of that kind to exist as a mere matter of policy, to say nothing of humanity ?—I do not think that they would. Whenever we hear that question (and I have heard it asked scores of times when I was an agent), we say, "Very well, you go and do the best you can, and we will get a machine as soon as possible." We have, perhaps, a machine out of use, and we apply it directly. I never saw an instance of men complaining without something being done to remedy it.

2317. You very frequently do not stop the work, but you say, "Go on as well as you can, and we will remedy it ?"—Yes. I should think that the man who gave the evidence which has just been read about the candles is no miner, because if you have got a candle made of the best cotton, if that candle goes out, you cannot blow it up again ; but they get the best cotton and some of this inferior cotton put together generally. If that candle goes out you can blow it up again in a moment, but if you have a candle which is made solely of cotton you will never blow it up.

2318. Will the cotton give as good a light as the other ?—No.

2319. Of course, sometimes before you can get a connexion, and where there is great difficulty in sending in air, men may have to work in bad ends ; but did you ever know an instance in fair mining of men being obliged to work in bad air for as much as three months consecutively ?—They are not obliged to do so.

2320. But do they do so ?—Yes ; I have no doubt that there have been instances of it.

2321. Do you think that you have had any instance in South Caradon of men working three months in such an end ?—I cannot say at all.

2322. But it is possible ?—It is possible in any mine.

2323. With regard to boring, does much dust arise in boring ?—Yes.

2324. Injuriously to the men, in your opinion ?— No doubt about it, particularly when you commence your hole. For instance, the men will hole, and the head, perhaps, is close to the bit where they begin to bore, and at every blow of the borer the dust flies all round, and they must be constantly inhaling it.

2325. Can you suggest any remedy for that ?—No, I do not see what you can do.

2326. You refer to mundic and to copper and to slate ?—Yes.

2327. In certain positions the men must have a dust, which is injurious to them ?—Yes, because when you are working upon the lode, a miner will always do with as little room as possible, particularly if the ground is hard on each side, then you would be sometimes surprised to see the men, and you would be afraid that they were knocking their heads.

2328. Will you refer to that plan ? you observe that some men are supposed to be waiting there. Do you think that, generally speaking, men come out much before their time, and remain there afraid to go to the surface ?—I do not think that they do.

2329. And that they catch cold, being afraid to come up ?—I do not think that it is the case.

2330. Would not the agent himself prevent that ? —The agent of the mine would go and endeavour to catch them there, and he would find them directly ; you may depend that it is not so, I do not mean to say that there never was an instance.

2331. But you think it is not at all common ?—It is not general, depend upon it.

2332. Do you feel sure upon that point ?—I am quite certain of it.

2333. I suppose it is a long time since you had a pick in your hand ? — Yes, but I can recollect it perfectly well.

2334. Suppose you were to be 100 fathoms or a long way in, where there was no ventilation at all, and with bad air, and where the ground had cost in driving 8*l.* a fathom, how many single holes could be bored in eight hours ?—About three.

2335. In bad air ?—I cannot tell if the air was very bad.

2336. I am talking of an adit 100 fathoms or more driven in without any ventilation at all ?—I have seen nearly as good air in a place 100 fathoms in, and where the level is straight, but if you have turns it becomes worse.

2337. I am talking of very bad air ?—Then perhaps they would not bore more than two.

2338. With regard to the watches and the time that is kept, do you not think, taking the miners as a body, that in their time of changing they are generally tolerably correct ?—Yes, they tell very near indeed.

2339. Do you feel satisfied that there are many men who carry watches underground ?—Yes, I have done it, and I have seen scores do it.

2340. If a man has a watch, does he not like to carry it underground ; is he not proud of his watch ? —Yes.

2341. Did you ever know a captain object to a watch ?—Never.

2342. Did you ever hear of such a thing ?— Never.

2343. With regard to the ventilation, has it not been much improved since the time you can recollect ?— Very much so.

2344. Do you think that every day the miners' comforts are very much improved above-ground ?— Yes.

2345. But do you think there is still room for improvement ?—I do not know, because we have not studied the thing very much; there is no doubt but that

improvements may be made in some mines; for example, you may find now, in going through some of the metallic mines, no dry; but what I mean to say is, that, generally speaking, mines of any magnitude now-a-days have drys.

2346. And in those drys I suppose there is no objection to dry the clothes of the men who come there?—No; the clothes they wear.

2347. As well as the clothes they wear underground?—Yes.

2348. They take their working clothes, and go underground with them on, and if they return with them wet, they are dried?—Yes, they are dried and hung up in places until the morning, when they come.

2349. So far as the habits of the miners go, do you think they are much improved?—Yes; they have much improved in the last 20 years.

2350. You do not think that they drink so much?—No.

2351. They are more careful, are they not, with regard to bad air, and they will not go into it?—Yes, I am sure they are.

2352. What are the average gettings in your mine?—You must keep the tutmen separate from the others, if you put the tributers with them it throws the average up considerably.

2353. But in the district what are the average gettings of the tutmen?—In the district they are from 3*l.* 5*s.* to 3*l.* 10*s.*

2354. What do the tributers get?—They get more, for instance, if one should get what is termed a start, they may get, perhaps, 40*l.* or 50*l.* in a month, and that throws the average up considerably on the whole.

2355. (*Mr. Davey.*) With regard to boring, you say that when they are boring in the back, the man's head is close to the hole?—Yes.

2356. How deep would it be before he could prevent that?—It would be by the time the hole was about six inches deep.

2357. Can you always put something round so as to prevent any dust coming out?—That is not done except where you go a little on the incline, and you are boring near water, then you have a mop put about it.

2358. What number of holes do you suppose it would be necessary to have in the back of a level where you could not prevent the dust from coming out?—It is in the stopes, that is, where they are working in the back.

2359. As they would in the level?—Yes; they would sometimes. At the back of the end, the persons holding the borer would not be so near as they would in the back when they are rising in small gallies.

2360. There would be a very small proportion of the holes that produce dust as compared with the others?—It is only at the commencement; when a hole is cut down four or five inches deep, there is nothing of the sort.

2361. (*Mr. Fulke Egerton.*) Have you known many miners suffer from what is called the miner's disease?—Yes.

2362. Do you think fewer suffer now than have suffered in the past few years?—I think the number is smaller.

2363. Do you think that is because the captains look more after the ventilation, or because the men themselves look more after it?—I think it is both; the men are a little more particular, and the captains look more after it, and not only that, but the men's comforts are more attended to than they were 20 years ago; and I firmly believe, whoever lives to see it, that 15 or 20 years hence there will be less of that disease than there used to be, or than there is now.

2364. Have you had any experience in the deep mines of the west?—Yes. I have been in the mines a great number of times.

2365. Do you think that the same observation applies to them as to those in this neighbourhood, that the ventilation is more attended to and the condition of the miners improved?—I have no doubt that it is, generally speaking; but I cannot speak positively about it.

2366. (*Mr. Austin Bruce.*) What proportion of your men are engaged in tutwork out of the whole number?—I should suppose that there is more than one-half at present.

2367. As a rule the tutmen are working in worse ventilated portions of the mine than the tribute men?—Yes.

2368. I suppose that a certain portion of the close ends, do what you may, are ill-ventilated?—There are some, but not a great number; but then you find, as I said just now, that there are winzes sunk as often as it is at all advisable. With a regular mode of mining, and when there is a long distance between the winzes, we always endeavour to put in a machine.

2369. You do your utmost to diminish the evil; but still it exists, and must do to a certain extent?—It must exist in certain places, particularly in cross-cuts.

2370. You have spoken of men having worked continuously in bad air for three months?—Yes, I have no doubt that some of them have.

2371. Are there any instances of that kind in your mine at the present time?—No, not to my knowledge.

2372. What is the greatest length of time for which in your opinion men now work in bad air in your mine?—Really we have very little of anything of that sort in the mine at all, because as we have so many lodes, and so many cross cuts and shafts, our mine is really very well ventilated.

2373. You have spoken of the men working continuously for three months in bad air?—That was not from my own knowledge, I said that I had no doubt about it.

2374. Speaking from the knowledge you have of the surrounding district?—Yes.

2375. You have reduced the amount of bad air to a minimum?—Yes, it is very much reduced to what it used to be.

2376. But you are of opinion, I presume, that your own mine is a favourable specimen?—I do not know, not particularly so. In most well-conducted mines they have a great many shafts, I suppose that we have 9 or 10 shafts in our mine from the surface altogether, and in some places there is a difficulty in carrying a light, the draught is so strong, and that is the case in many other mines. You will find in some instances that the comforts of the men are not well attended to, but, generally speaking, they are much better attended to than they used to be.

2377. You have said that your men complain and that their complaints are always redressed?—I have never known an instance but what they were; the moment the complaint is made there is always something done directly to endeavour to remedy it.

2378. Of course that would depend upon whether the thing was feasible without unreasonable expenditure?—Yes.

2379. Have you close ends to drive which must be driven, whether the ventilation be good or bad?—Yes, for instance, suppose that you had got a winze coming down here (*describing the same*), and the level coming on towards it, and this (*pointing to the same*) was a good way off the winze; it would be a very considerable expense to do anything to relieve it, and then perhaps you would not have more than a fathom or two to drive to alter this winze, when you would have plenty of ventilation, and the men might be working in a bad place just at that time.

2380. You said that the candle indicates the existence of bad air before the men feel it?—Yes.

2381. Are you sure of that?—Yes; I have been many times in places where the candle would not burn. I have worked on a tribute when I had the candle, perhaps, seven or eight feet behind me; it would not burn where I was working, and we were doing very well, and you do not think about the injury then.

LISKEARD.

Mr. P. Clymo.

16 April 1862.

2382. But you were injuring yourself?—Yes, no doubt about it.

2383. You have told me that you have worked when actually the candle would not burn, and my question is whether to a certain extent the air would not be tainted even before the candle by not burning showed the condition of the air?—No; you will find that wherever there is a little failure in the air the candle will show it, and instead of having the candle upright it must lean; as the air gets worse you must have it down in a horizontal way.

2384. I understood you to say that you gave over working in the mine at the age of 23?—I gave over working when I obtained a situation.

2385. And that was at the age of 23?—Yes.

2386. Had you at that time suffered at all from working in close ends?—Not that I am aware of.

2387. I suppose you were without difficulty able to choose the ground in which you would work?—Generally speaking, I worked on tribute when I was underground, although I have worked on tutwork, and as I aid before, the tributers have better ventilation generally.

2388. How many workmen do you employ in your present mine?—I think altogether there are nearly 500.

2389. Is there a doctor's fund?—Yes.

2390. Are the miners attended by the doctor without payment?—Yes; there are two doctors.

2391. Are there any miners now under treatment for what is called the miner's disease?—I do not know, but I do not think there is so much of that in this neighbourhood as there is in the west; it depends a good deal upon a man's constitution; for instance, you will see two men coming up the ladder, one man is a strong healthy man who has got good wind, and you will find another who has not got nearly such good wind, but he will not be outdone by his comrade, if he can help it.

2392. (*Mr. Kendall.*) You say that you can judge very well by the burning of the candles as to the state of the air?—Yes.

2393. And you came to this conclusion when you were a tributer, that you could often work in an end where the candle would not burn, and you put it back some eight or nine feet behind you?—Yes.

2394. Then the candle according to that is more sensitive than a human being?—Yes.

2395. You can work where a candle will not burn?—Yes; the candle in the place that I spoke of, the moment you put it in, went out directly.

2396. With regard to the holing, if you are driving to meet a winze, and you find that you are very near, and the air becomes bad, then as it might cause some expense to bring in air, you prefer very often to let the men work on in the bad air?—Yes, giving them an extra price for the work, for in a short time they will get ventilation.

2397. But might it not take a long time, say two or three months?—After two or three months we should put in a machine.

2398. (*Chairman*). Do you suppose that in every mine there are ventilating machines?—In every mine, I have no doubt of it.

2399. Do you think that there are machines for ventilation in every young mine?—When they are required, but they are not required in a young mine until the works get extensive.

2400. When the levels are so extended as to produce foul air, do you think there is sure to be a machine put down?—Yes, different machines in any mine of any extent.

2401. If that be so, why are complaints made as to the foul air? you have stated that there were men working in bad air, but if there are these machines, why are complaints made?—There are particular places we may expect in a short time to hole to a certain place where there will be a communication, and you may then have a close place for some time, perhaps for a few weeks or a month, and you would not go to a greater expense; and probably then you would give the men an extra price, and they would get on with the work as soon as possible.

2402. But would they not do that to the injury of their health?—Very little injury.

2403. In a poor mine I presume it is less likely that they would go to any extra expense when they are perhaps merely exploring?—You will find that the agents will be more particular than they ought to be.

2404. But generally they would let the men work on to enable them to get to an end?—It might be the case, I cannot say that it is so.

2405. You have stated that there are some mines where the comforts of the men are not so well attended to?—I think you will find that that is so.

2406. You have also stated that the complaints which are made are more attended to than they were 20 years ago?—Yes.

2407. Are they more attended to now than they were 10 years ago?—I think so; there is no doubt about it.

2408. Are you of opinion that there is a general improvement going on?—Yes, you may depend upon that, as to the comforts of the men throughout the country.

2409. Evidence has been given before this Commission, referring to the state of things some seven, eight, nine, or ten years ago; the complaints of the miners then may not have been so well attended to as they are now?—No.

2410. Do you know anything of the Caradon Consols mine?—Yes.

2411. Do you remember that being commenced, and the shaft sunk?—Yes, I was an adventurer there, when they first commenced.

2412. You sunk one shaft?—Yes.

2413. Will you be good enough to describe to the Commissioners what was done there?—The shaft was sunk down to a certain depth, I think 30 feet under the adit.

2414. Was the adit extended?—Yes, it was holed to that shaft, and the shaft was sunk about 30 fathoms under it, that was in the first working.

2415. Before they holed to where the engine shaft is, what distance was there between the engine shaft and the shaft which you sunk first?—Really I cannot tell now, it is many years ago; but I think there was a shaft between, sunk down for ventilation as well as I recollect.

2416. Was the air bad in it while the men were working?—I do not recollect, I have been there, but I was only an adventurer, I was not underground but seldom.

2417. But in the case of sinking a new shaft, and then driving the adit at the end of that adit, it is very probable, is it not, that the air would be bad?—If it extended a long way it would naturally get close, and particularly where you have harder ground where you must blast.

2418. And where it is not straight?—Yes, more particularly so; then again where you are obliged to timber, the air is not so good as when there is none.

2419. Is timber affected by the damp?—Yes; that is the case, it is in a soft state and gets very weak.

2420. That I suppose vitiates the air?—Yes.

2421. Do they never put hemp into candles instead of cotton?—I believe not; it is a mixture, I think, generally speaking.

2422. A mixture of hemp and cotton?—Yes.

2423. Not inferior cotton, and good cotton mixed together, but hemp and cotton?—I think there is some hemp.

2424. Should you prefer a candle made of hemp and cotton mixed?—Yes, it gives a better light, and not only that, but the men sometimes in driving home through a level the candles will go out, and then you cannot blow them up again if they are made with nothing but cotton, but with hemp mixed you can.

2425. You stated that you knew that sometimes the candles supplied by contract were of inferior

quality ?—Yes ; I have no doubt that they are sometimes.

2426. Therefore it is possible that in inferior candles more hemp may be put than cotton ?—It is more with regard to the grease than the wick.

2427. Would it be any saving to the manufacturer to put hemp in instead of cotton?—The hemp would be cheaper, no doubt.

2428. Then it is quite possible that a man might put hemp in if he wished to commit a fraud ?—They may put in more sometimes, but as soon as it is detected a complaint is made directly ; for example, last Saturday week we had to order some candles in our lead mine, and the question was asked, "Where "did we have the last from ?" "From so and so, but "the candles were not good." Then I said, "Do not "send the order there, but send the order to Ply-"mouth ;" and we sent there immediately, and the other man lost the order.

2429. But suppose you had made a contract with a man for six months' supply, would not the man in that case be obliged to use those candles ?—We always make a reservation when we make a contract, and say, "If you do not send good candles we shall "order them elsewhere, and charge you with the "difference in price."

2430. Suppose that any mine agent has made a contract for a quantity of candles that are inferior, would he not probably let the men continue to use them ?—If the men complained of them I should think he would not ; we have sent back scores of boxes.

2431. (*Mr. Kendall.*) If they do not come up to the sample they are returned ?—Yes.

2432. (*Chairman.*) How long is it since your dry has been erected ?—One has been erected for several years.

2433. The new one ?—I cannot tell you how long that has been erected, not more than 12 months ; we have more men employed there than before, and we had therefore not room enough. Then there was one that we had in the higher part, we had one up at the head that was burned down, we had not room altogether for the men, and when that one was burned down we agreed to build them a new one, and now we have plenty of room for the whole of the men.

2434. Have you ever been to Fowey Consols?—Yes, but not for some years.

2435. You perhaps do not know whether there is a dry there or not ?—No.

2436. (*Mr. Davey.*) You stated just now that you were an adventurer or shareholder in the Caradon Consols ?—Yes.

2437. Is it probable that you would drive an adit 130 fathoms, only 15 fathoms from the surface without ventilation ?—It is not at all likely, where there was but that distance, no doubt, there would be a shaft sunk on purpose for ventilation.

2438. You could drive a level more expeditiously, could you not, and consequently much more cheaply ?—Yes.

2439. How do you find the miners generally ? do they appear to you to be an independent class of men ?—Like all other classes, they are different ; but some of them are very independent.

2440. For example, if you were to insist upon anything being done in the mine, and they did not choose to do it, would they take up their hats and walk away ?—Yes ; there have been instances of that kind. It might be said to them, "If you do so and so, you "must go," and they would leave ; but generally speaking where you have a proper system and things are to be attended to, they know what the rules and regulations are as well as we do, and we have very little trouble with them.

2441. (*Mr. Kendall.*) Suppose you were to make innovations in any way, would they submit quietly to them, or would they say we do not like it ?—Many of them say, "We do not like it."

2442. As a body do you consider them to be a tolerably independent class of men ?—Yes.

2443. Which in your opinion is the most independent, the agricultural labourer or the miner ?—I think the miner is.

2444. (*Chairman.*) Should you say that the tut-work men are as independent as the tribute men ?—They are pretty much the same.

2445. Are they not very often compelled to work, and from necessity in bad ends ?—There is no necessity, because a man when the work is out can leave at any time.

2446. But is work so plentiful generally that he could obtain work elsewhere if he threw up his work at any particular place ?—Yes ; now it is the case.

2447. (*Mr. Kendall.*) Suppose that a man were in a bad end, and he said to the agent, "I do not like "the air at this end, I shall give up my take there," would that operate as a bar to his working in any other part of the mine, or, in other words, would he be a marked man ?—No.

2448. Would any part of the mine be as open to him as to any other miner ?—Yes ; the agent would not put himself out of the way. If he liked to take a pitch, he might take it directly if he were a well-conducted man.

2449. (*Chairman.*) I suppose there must be many miners who are not earning large wages, but who have large families, and are obliged to take work which, if they were as independent as tribute men, they would not take ?—I think there are more tributers badly off than tutmen. The tutmen get pretty regular wages, but the tributers may go on sometimes for two or three months, and get but very little, and the men who, I think, are in the greatest poverty are the tributers. Then again a great deal depends upon a man's wife. In this neighbourhood there are scores of them ; but between them there is as much difference as between light and darkness. You will find two men, and one of the two has got a clean, decent, wholesome, industrious wife, and that man's children will be kept as clean and as comfortable as possible ; you will then see one of the same pair, who has got a dirty, careless wife, and the family will be in rags, and yet that man will make the same gettings, and his house will be in the greatest mess possible. You will see the one man going on as comfortably as possible, and the other will be always in misery.

2450. What are the wages that the tutmen have earned during the last month, or at what rate have they taken sets at ?—I think that our men would average somewhere about 3*l.* 5*s.* to 3*l.* 10*s.*, some more and some less ; some men are much better men than others. If you give them the same price for the ground they will get perhaps 10*s.* a month more than another man, and therefore some will get more and others less.

2451. What should you say was the least ?—Some of them, if the ground is against them, will not make perhaps more than 2*l.* a month, and even less than that sometimes in bad ground. You set to a pair of men and you give them 4*l.* a fathom, and, before they have half driven six feet of ground, the ground will become such that they ought to have 7*l.* or 8*l.* a fathom ; then those men are thrown back, and sometimes men will drop their tools, and run away and leave it. But we are never in the habit of taking out a bargain of that sort, because if the ground goes the other way we never attempt to keep back anything ; we pay them what they earn, and we take the bad with the good.

2452. If it is bad they do not get any more, although it is a bad bargain ?—Instead of 3*l.* 10*s.* they would not get more than 2*l.* or 30*s.* If they are steady men we charge them with what they call subsist ; we advance a sum of money on the month then out—for instance, if you are going to pay next Saturday, you would pay for the work done in March month ; then you would have a month in hand, and we should advance them a little money to take it up, perhaps 10*s.* a man, or 1*l.* upon the month after, to enable them to purchase provisions for their families.

LISKEARD.
Mr. P. Clymo.
16 April 1862.

2453. Is it generally the case that they are a month behindhand in their pay ?—It is generally the case.

2454. What is the reason of that ?—We have some little hold upon the men by that, they would not be running about and leaving their work so much.

2455. So that a man commencing work is not entitled to his pay for two months ?—No, unless he had some advanced to him, but when a man leaves a mine he has a month's wages coming from that mine.

2456. That is supposing that he is not out of work ?—Yes, if he is out of work he gets nothing, but at the end of the month we advance him some money, there is hardly a month but what we do that.

2457. Are the wages you have mentioned clear of all deductions ?—Clear of all costs, that is the money they carry home.

The witness withdrew.

Mr. WILLIAM JOHNS examined.

Mr. W. Johns.

2458. (*Chairman.*) What is the name of the mine of which you have the management ?—West Caradon.

2459. How many men have you employed underground ?—About 450 men, women, and children. That is what we call our complement, it varies at times.

2460. How many of those are working underground ?—About 300 working men.

2461. How many shafts have you in the mine ?—Four.

2462. Is West Caradon connected with any other mines underground ?—There is a connexion between West Caradon and South Caradon, and with Gova Meva, they all communicate one with the other.

2463. That I suppose helps the ventilation ?—Yes, it causes ventilation throughout the whole mine.

2464. Then the ventilation is good ?—Very good indeed, I think the best that I ever was in.

2465. For how long have you worked in the mines ?—From my boyhood upwards, I was a working man upwards of 20 years, and I have been manager about 12 years.

2466. Have you always been at this mine ?—I have been at this mine for the last three years and three months.

2467. Were you in the west before that ?—Yes.

2468. In what part of the country did you work as a working man ?—Principally at Redruth and Gwennap.

2469. Have you worked in very large mines ?—I worked in the Carn Brea mine for many years.

2470. Have you ever been at work in the close ends and in bad air ?—I never had occasion to work in the close ends. I worked principally as a tributer.

2471. What was your reason for working as a tributer ; was it to avoid the close ends ?—No ; but I fancied that the tributers could earn more than at tut-work, as a whole.

2472. But to work as a tributer must you not have some means of your own, as you may not earn anything ?—We generally calculate that we get extra means, and are able to put something aside ; taking the whole year round, we generally calculate that the tribute men do better than the tut-work men ; they work longer hours, generally speaking.

2473. They are able to do that, are they not, on account of breathing better air ?—I do not know ; it depends upon circumstances ; sometimes we earn something extra.

2474. When you have got a good lode ?—Yes.

2475. Should you say that where the tribute men work the place is generally better ventilated than where the tut-men work ?—It is generally pretty well ventilated in some instances ; there might be a little foul air connected with it, but we generally manage as tributers to work round, and get it well ventilated.

2476. You meant poor air when you said foul air ?—Yes.

2477. I suppose as a tributer you used the borer ?—Yes, the tributers use the borer as well as the tutwork men ; there is no exception with regard to that.

2478. In your present mine are there no bad ends ?—No. I should say that our mine is very well ventilated, because we have 13 or 14 different lodes in the mine, and they are well ventilated. I suppose that the extent, taking the different levels driven, is beyond eight miles, if it was opened out, and more than eight miles by communicating one level with another ; there is a communication.

2479. Is it a copper mine ?—Yes.

2480. Is there much mundic there ?—Yes, there is a portion of mundic.

2481. There is no artificial ventilation, is there ?—No ; we do our best to get well ventilated, and we ventilate it by sinking winzes.

2482. Have you any other artificial means of doing it ?—Should there be required a machine, a fan machine, we put it on.

2483. Are the fan machines worked by a boy ?—Yes.

2484. Have you ever seen any other means of ventilation used in any mines ?—Yes ; there are machines attached to the engines sometimes.

2485. Have you seen them at work ?—Yes, we use them in the mines we are connected with ; but that entirely depends upon how fast your engine works. Where it works four or five strokes a minute it can be blown down very effectually, but where the engine works slowly it will not be sufficient.

2486. I suppose the speed could be increased by a wheel ?—Yes, it could be multiplied.

2487. In what part of the county is the mine situated where they have a machine applied to the engine ?—There is one now working at

2488. Is that near to this place ?—Yes.

2489. Near your mine ?—Yes, in the same district.

2490. Is there only one shaft there ?—There is only one shaft in that mine.

2491. Is it a young mine ?—Yes.

2492. You have ladders, I suppose, in the mines ?—Yes ; our footways are principally through winzes on the course of the lode.

2493. It is not a direct ascent, but from one level to another ?—Yes ; we have a footway in our mine direct on the course of the lode, from the surface to the bottom of the mine on the different lodes.

2494. What is the greatest depth where the ladders are continuous ?—About 30 fathoms is the most continuous line of ladders we have got, but they are quite safe from the shaft to the surface.

2495. Are the men distressed by ascending them ?—Not at all.

2496. Have you a dry ?—Yes.

2497. Is that attached to the engine house ?—No, it is quite distinct from the engine house.

2498. Is it a comfortable changing house ?—Yes, as comfortable as we can possibly make it.

2499. Do the women work under cover at your mine ?—Yes, in some cases.

2500. I suppose they are the better for working under cover ?—Yes ; but they cannot always work under cover ; we work them all under cover as much as we possibly can.

2501. Have they any room set apart for themselves to enable them to boil their water for tea ?—We have three for the girls working on the floors at the different places, and they can warm their water for their tea or for their dinner.

2502. That, I suppose, is a great comfort to them ?—Yes, especially so in the winter time.

2503. Does that arrangement keep them separated from the men ?—Yes ; the men have nothing to do with them, not more than what are working on the floors.

LISKEARD.

Mr. W. Johns.

16 April 1862.

2504. Do you know anything at all about the ages of the men, or are there any old men working there ?—Yes ; their ages range from 60 to 13 or 14.

2505. There are some as old as 60 ?—Yes.

2506. Have they been working all their lives in the mines ?—Yes, they have ; and some men had been working in the mine before I knew anything of it.

2507. Working in a well-ventilated mine you think is not injurious to health ?—No, not so much as might be supposed by many others.

2508. Is there anything in the smoke of the candles or the powder that you think might affect the men at all ?—It is very likely that the smoke of the powder is not so good for the constitution as fresh open air, but they are not compelled to go into it. If they blast a hole in the end, they are not compelled to go in till the smoke has thoroughly cleared out.

2509. With a system of good ventilation, how long would that take ?—In some places the smoke is gone in five minutes, and in some others in 10 minutes.

2510. Is your ventilation affected by the atmosphere ?—I do not know, we have plenty of good shafts ; and the more you have of them the greater the draught.

2511. (*Mr. Fulke Egerton.*) Do the men who are employed pay a certain sum for medical assistance ?—Yes, they do.

2512. How much do they pay ?—We deduct 1*s.* 6*d.* per month from each man, one half of which goes to the medical assistant, and the other to the fund, should they be hurt.

2513. Do they receive a certain allowance from the fund whilst they are sick ?—Yes, they receive 1*s.* a day as long as they are sick.

2514. Is that allowance confined to the men who suffer only from accidents, or is it extended to those who suffer from illness ?—It is extended to both ; if a man should be poorly, and he is a steady working man, we give him 1*s.* a day, and when he is well enough and comes back again, he goes to the counting-house, and his name is erased out from the club book.

2515. Do you know how many men there are under medical treatment at the present moment on the books ?—There are two men whom we call infirm men, and they were infirm men before I came to the mine ; but those are the only two I know of, with the exception of the case of a small accident, who are on the club, out of 500 men one is a mere nothing.

2516. What is the greatest number of men who you can recollect have been on the club books ?—Perhaps seven or eight on account of small accidents, for some two or three days or a month.

2517. Have you had any on the books suffering from what is called the miner's disease ?—Not since I have been a mine agent ; not particularly that, but they get old and infirm like many other classes, and then we give them easy work to do at the surface, and after that if we thought it right we should give them a small remuneration as long as they lived.

2518. Have you had experience in other mines besides the one you have mentioned ?—Yes, I am agent in other mines besides that.

2519. Do you consider that the ventilation in this mine is better attended to than in other mines ?—There is very good ventilation in this mine, and we have an advantage in the way of ventilation in this mine over many others ; we have a great many lodes, and they communicate the ventilation to three different mines ; having such extensive workings, perfect ventilation is produced.

2520. (*Mr. Austin Bruce.*) Have you ever known the men at the close ends give over working in consequence of the bad air ?—No, not that I am aware of, that is, not entirely to give up ; there are some exceptions, sometimes we drive an end, and we have a winze go down before that end, and perhaps a week or a fortnight might accomplish the object, but some of them might take cold just during that time, but not give up entirely.

2521. You spent your youth in the west, did you not ?—Yes, having visited that district for about three years and three months.

2522. Did you know of much suffering there from bad ventilation ?—No.

2523. Did you ever know of any instance ?—Not one.

2524. Do you mean that you never knew a man suffer in that way in all your life ?—Not in the west, while I was a western mine agent I did not know of one being laid up from bad air.

2525. Have you known men suffer from what is called the miner's disease ?—They say so, but I never knew of one.

2526. Have you never heard a man complain of any sort of suffering in consequence of working in close ends ?—No, I never had any complaint made to me as a mine agent.

2527. Did you never hear of any complaint of that kind being made ?—People say so, but I never had any complaint made to me ; we always study the comforts of the miners, and if they have not good air we are obliged to give them extra air ; we do not get so much work done if they are in bad air.

2528. (*Mr. Holland.*) Did you suffer from what is called the miner's disease ?—Parties say that there is such a disease, and I have heard of such, but I never witnessed anything of the sort. I worked as a working man for 20 years, and I never suffered anything of the sort.

2529. (*Mr. A. Bruce.*) Perhaps you never worked in close ends ?—I worked principally as a tributor.

The witness withdrew.

Mr. WILLIAM COCK examined.

Mr. W. Cock.

2530. (*Chairman.*) At what mine are you captain ?—South Caradon, Wheal Hooper.

2531. Is that a young mine ?—Yes.

2532. How long has it been worked ?—About four years.

2533. Have you been there since its commencement ?—Yes, I was there at its commencement.

2534. Is there one shaft or two at that mine ?—Yes.

2535. To what extent have you driven the ends from the shaft ?—Our farthest is between 90 and 100 fathoms.

2536. At the end of that 100 fathoms what means of ventilation have you ?—We have an air machine attached to the engine, a piston machine.

2537. How is the air blown down to the ends ; is it in pipes ?—Yes, the foul air is taken out.

2538. The effect is to draw the foul air out ?—Yes.

2539. Are there two pipes ?—There is another pipe.

2540. (*Mr. A. Bruce.*) Is that Struvie's engine ?—It is a pumping engine.

2541. (*Chairman.*) How does it work ?—It is attached to the engine ; it works stroke for stroke with the engine ; it draws out the foul air, and discharges through another run of pipes to the surface.

2542. Is the fresh air sent into the mine by pipes ?—No.

2543. You exhaust the foul air from the mine ?—Yes.

2544. Does that plan answer perfectly ?—It answers very well.

2545. Are there no complaints at the far end of this mine ?—Not when the men keep the pipes in proper condition.

2546. How many different levels have you below ?—Only one.

2547. Is it straight ?—Yes.

2548. The engine draws the air from the extreme end. How does the fresh air find its way in ; is it from the exhaustion of the other ?—Yes.

LISKEARD.

Mr. W. Cock.

16 April 1862.

2549. What are the pipes that you spoke of?—They are the passage through which the foul air is drawn.

2550. To the engine?—Yes.

2551. At the far end, while the men are working, can the candles burn?—Yes.

2552. Have you ever seen the candles fail there at all?—Never.

2553. You have been a miner yourself, have you not?—Yes.

2554. In what part of the county did you work?—At St. Agnes.

2555. In deep mines?—Ninety fathoms.

2556. Was there any poor air at any of the ends in the mine you were working in?—Yes.

2557. Did you work as a tut-worker or as a tributer?—As both.

2558. As a tut-man, did you ever encounter bad air?—I have in some places; I have worked in different mines.

2559. In some places have you met with poor air?—Yes, I have in some cases.

2560. How did you discover the presence of the poor air, by the burning of the candles or by your own feelings?—By the burning of the candles.

2561. Did you find that it affected your health at all?—I do not know that it ever did.

2562. Did it produce any sensation while you were working?—No.

2563. You felt no effect from it whilst working?—No.

2564. Was it very poor air or not?—Not very bad.

2565. Was the other man who was working with you affected in any way?—Not at all.

2566. I suppose the shaft is divided?—Yes.

2567. The exhaustion of the air takes place through the ladder shaft, down which the men go, does it not?—Yes, the foul air is discharged at the surface through the pipes.

2568. Do you suppose that the fresh air finds its way down the lift?—Yes.

2569. Is the division of the shaft close, or is it open wood work?—It is close.

2570. Quite close?—Pretty well.

2571. It is not stopped up in any way?—No.

2572. Do you know what was the cost of this engine for exhausting the air?—I should think not more than 20*l*.

2573. Is that much for such an engine?—Not a great deal.

2574. What horse-power should you think it would take to drive it?—I should think four or five horse-power.

2575. Do you think that could be applied to any mine?—Yes.

2576. From your experience of it does it get out of order?—It draws about 200 cubic feet a minute.

2577. Has it ever got out of order?—Not since it has been working.

2578. From your experience would you recommend it to be adopted in mines where ventilation is required?—Yes.

2579. (*Mr. Davey.*) You stated just now that you had always good air in the mine as long as the pipes were kept in order?—Yes.

2580. Do the men sometimes neglect to keep the pipes in order?—Yes, they do.

2581. The consequence of that, I suppose, is, that they find a difficulty in working?—Yes. Those pipes are made in about nine feet lengths, and at the joints where they do not fit they are stopped up with clay, and by means of water sometimes the clay works out, and it requires to be renewed with clay or grease.

2582. Which the men, I suppose, neglect to apply?—Yes.

2583. Why do you stop up the parts where they do not fit with clay? Could you not find any other means of stopping them up better than clay?—Sometimes they are stopped with grease, and that would not wash out.

2584. As long as the pipes are properly attended to, you get very good air?—Yes.

2585. Had you ever seen any of those machines before?—Yes.

2586. At what mines?—At West Caradon.

2587. Have you seen any of that description in St. Agnes?—No.

2588. What mines did you work in?—At Consols.

2589. That mine being worked entirely by tributers, you always had good air, I suppose?—That mine is well ventilated generally.

2590. (*Mr. Holland.*) What size is this ventilating engine?—Twenty-four inches square.

2591. What is the length of the stroke?—Eight feet.

2592. That would be a 32-feet stroke?—Yes, it is double.

2593. How many strokes does it make a minute?—About three.

2594. About 200 feet a minute?—Yes.

2595. How many men does it supply with air?—Six; only two at a time.

2596. Is there a pipe that goes through the end to draw the air away from the end?—Yes.

2597. Does that connect with the division of the shaft?—Yes.

2598. Is the division of the shaft air-tight?—Not quite.

2599. Is there an air pipe all the way up?—Yes.

2600. What size is that?—Five inches.

2601. It is a duck engine, is it not, like a gasometer rising up and down in a tube of water?—No, not with water, it is worked by valves similar to a steam engine.

2602. Do you find that that is sufficient to keep the mine cool and sweet?—Yes.

2603. (*Mr. Austin Bruce.*) Have you ever heard of the disease called the miner's disease?—Yes, I have heard of it.

2604. Did you ever see anybody suffering from it?—I have seen men with a disease upon them in a consumption, I suppose; as it is commonly called the miner's disease.

2605. How do they show it?—By a shortness of breath generally.

2606. Where did you see those cases?—They are to be seen in most mining districts.

2607. Have you ever found any of your fellow-workmen suffering from it?—No.

2608. Have you ever known many men of your acquaintance suffering from it?—I do not know that I can name any one.

2609. Have you ever worked in close ends?—Yes, I have worked in a few.

2610. Were you ever at all the worse for it?—I do not know whether I was.

2611. Have you ever felt any increased difficulty in breathing in those places?—Yes, I have.

2612. Were you none the worse for that?—My staying in it was short, only just to examine it; that was one place that we have now raised from one level to another to give better ventilation, and in rising in this place the air was very scanty.

2613. What did you do?—We effected a communication between the two levels by a rise.

2614. How long was the air scanty?—For about three months.

2615. Were you working there all the time?—No; I was then an agent.

2616. Were there some men working there for the whole of the three months?—Yes.

2617. Were they the worse for it?—No; they are still working in the mine.

2618. Were they any the worse for it at the time?—No.

2619. (*Mr. Davey.*) You stated that you felt inconvenienced by this scanty air, did not the men who

worked there feel the same inconvenience ?—I believe not.

2620. Could they continue to work in a place where you could not remain to examine it ?—Yes.

2621. Did those men never complain ?—No, they complained that the air was foul of course, but that is like a good many others ; the place is put there entirely to afford better ventilation to the other parts.

2622. Do you think that the men generally suffer less after being accustomed to work in these places ?—I think they do.

LISKEARD. *Mr. W. Cock.* 16 April 1862.

The witness withdrew.

Adjourned to To-morrow at the South Caradon Mine, at 12 o'clock.

REFORM CLUB PALL MALL

Thursday, 17th April 1862.

PRESENT :

The Right Hon. Lord KINNAIRD, K.T.
The Hon. A. FULKE EGERTON, M.P.
H. AUSTIN BRUCE, Esq., M.P.
JOHN ST. AUBYN, Esq., M.P.
P. H. HOLLAND, Esq.

The Right Honourable Lord KINNAIRD, K.T., in the Chair.

The Commissioners made a personal inspection of SOUTH CARADON MINE, *at which they took the following evidence.*

A MINER examined.

2623. (*Chairman.*) How many years have you worked as a miner ?—27, I am now 42 years of age, I was 16 before I went underground.

2624. Have you worked at tutwork ?—Yes.

2625. And in poor air ?—Yes, formerly. At one time I worked in a mine under the river where the air was very light. In the granite where the air is dead there is a damp, it will act on the head first, and you get a tightness in the head, and afterwards it will cause an overflow of bile, and make you very sick.

2626. (*Mr. Fulke Egerton.*) Like a sick head-ache in fact ?—Very much like a sick head-ache, and afterwards when you work in poor air again you feel it directly ; it will act upon the system even for years afterwards, and in working in good air after the poor air you feel it more, if you do not take medicine ; I had to take opening medicine directly on working in poor air, and it worked it off, and it relieved the system. In the damp air the candle wavers, it beats down, but in light poor air it will extinguish.

2627. (*Chairman.*) Which do you think is the worst ?—The damp, what the miners call the cold damp.

2628. Is that principally in sinking the shaft ?—Yes, and you sometimes get it in extending levels, and sometimes rising in the back from the long distance where there is no current of air.

2629. Would ventilation cure that ?—Yes, certainly. Where there is the damp when you explode, the powder smoke will rise perhaps half up the shaft, and will not ascend to the surface ; the damp will keep it down there, and many men have lost their lives in consequence, after it has exploded.

2630. Is that from the damp or from the powder ?—From the damp air ; powder does not affect us so much as people think, because there is charcoal in the powder.

2631. How would you ventilate that ?—By sending down pipes and blowing air.

2632. With what kind of machine ? — A fan machine.

2633. Worked by hand ?—Yes, we had several in this mine.

2634. (*Mr. Fulke Egerton.*) Was that on the surface or at the bottom of the shaft ?—The fan machine was on the surface. We are obliged to do it to get the shaft a certain depth, to make a level to get a current of air through. In sinking a new mine in the summer time we get the cold damp, in winter time we do not get it so often.

2635. (*Chairman.*) Do you think that in sinking new mines you encounter more bad or damp air than in large mines ?—Yes, until the mine is ventilated. After it is ventilated if there is one shaft on the top of a hill and another lower down, it is drawing through a regular current of air. The adit will do instead of another shaft.

A Miner. 17 April 1862.

2636. (*Mr. Fulke Egerton.*) This mine is very well ventilated, is it not ?—Very. I think that it is a model for mines in general ; there is such a thoroughfare ; there are West Caradon and Craddock Moor and South Caradon, nearly adjoining East Caradon ; there is a thoroughfare right through, and there is Gonamena ; they are all connected, so that a current of air passes through.

2637. East Caradon is not so well ventilated, is it ?—I am afraid not, by what I have heard. I have not been down in it. I have worked in the United mines.

2638. Where are they ?—In Gwennap.

2639. (*Chairman.*) Are they well ventilated ?—Yes ; but they are very hot ; they cannot extend far from the shaft on account of the air. If they can get a waterfall they will do. Water throws the purest air, but in all mines we cannot get it. This mine has been working many years, and has so many shafts that there is a good ventilation.

2640. Do you know anything of Wheal Morris ?—No ; I was never in it. That is a new mine, and there is what they term Caradon Slade ; that is a new one ; that is a little way from Bodmin Land Village. I live at Bodmin Land Village. To inspect the mines, there ought to be a practical miner—one who has had experience for 25 or 30 years, and then he can tell the distance of the levels.

2641. What kind of work are you on ?—I work on tribute. When we work on tribute we are up dressing the ore for a week or so at a time in the pure air, and that invigorates our system ; it throws off the gases which we inhale underground. Some go underground earlier than I did. I did not go underground till I was 16.

2642. (*Mr. Fulke Egerton.*) In your experience do you think that ventilation has improved all mines ?—A great deal in the last 20 years. The places which are extended horizontally are larger ; they make them now for small tramways. Formerly they were only so that a little boy could pass through with a barrow. I think that the better a mine is ventilated the better it will pay the adventurers.

2643. The usual height of the levels is about seven feet, is it not ?—Yes, usually ; they ought never to be driven less than that.

The Commissioners then inspected WHEAL NORRIS MINE, *where they took the following evidence.*

Mr. JAMES NANCE examined.

2644. (*Chairman.*) You are the agent of this mine ?—I am.

2645. What do you think is the great cause of the miner's disease ?—The men blast their holes, and

Mr. J. Nance.

LISKEARD.

Mr. J. Nance.

17 April 1862.

then there is no possibility of getting to work for some time till the holes are cleared out.

2646. (*Mr. Holland.*) About what time?—Perhaps half-an-hour sometimes, and sometimes three-quarters of an hour. They bore so much ground, and perhaps sometimes it is not quite so hard, and it is done more quickly at one time than at another. While in a state of perspiration they get in a draughty place, and stop there till the bell rings in order to prevent any collision with the agent, and there they contract their consumptive habits; I believe that to be the chief cause of the miner's complaint.

2647. (*Chairman.*) Do they ever stand waiting on the ladders before coming up, because if they came out before the time they would be fined?—There is no doubt they do; they stop in a draughty place; I believe that the miner's complaint generally begins with a cold, and that a succession of colds produces it.

2648. Then you think it very desirable to have a good changing house near the footpath?—Yes, and especially in the winter time.

2649. (*Mr. Holland.*) Your belief is that if the miners stopped there instead of down below they would escape the miner's complaint?—I believe they would to a large extent.

2650. Do you think that miners suffer very much from dust?—In some rises in rising there is no doubt they do.

2651. Does it do them much harm?—No; I do not think it does.

2652. Does it ever make them short-winded?—Generally speaking the rock is damp.

2653. Do they suffer much from powder smoke?—If they go into it too quickly of course it will be injurious.

2654. Do not they commonly go into it too quickly?—I think not.

2655. Have you worked in poor air?—Yes.

2656. What effect has it had upon you?—You feel very little from it when you are in it, but the sensation in coming into the fresh air is very singular; you feel a weakness for a minute or two, which you did not feel before.

2657. You feel an amount of fatigue far more than proportioned to the exertion?—Yes.

2658. Do you feel a shaking of the legs and knees?—Yes, when you get into the fresh air.

2659. Do you sometimes feel frightened and nervous without any apparent cause?—No, I think not; you feel a sensation on getting into the fresh air.

2660. (*Mr. A. Bruce.*) How long does it last?—Perhaps for two or three minutes; persons who work in those close places feel chilled considerably more than persons working in good air places.

2661. Is that all you feel?—That is all I felt, because I was never so much in it as some of them.

2662. (*Mr. Holland.*) Have you ever had indigestion produced by bad air; such air as you have described?—Not that I recollect. I have felt a little indigestion latterly.

2663. (*Mr. A. Bruce.*) How long were you underground?—In my training I was underground four years, but nothing more than being trained.

2664. (*Mr. Holland.*) Did you ever work in bad air?—One month.

2665. What was the state of your health at the end as compared with its state at the beginning?—I felt languid and feeble after the end of the month, rather more than I was before.

2666. Did it produce head-ache?—I have been subject to head-ache, I think, from my childhood, at times, but I do not recollect to have had any particularly from that cause. Close misty weather used to bring on head-ache with me.

2667. Have you noticed a loss of effective time from working in bad air?—I have never done so.

2668. (*Chairman.*) How much do you think it takes out of a man to go up the ladders 100 fathoms?—I should think a quarter part of his day's work.

2669. (*Mr. A. Bruce.*) Equal to two hours' work?—I think so.

2670. (*Chairman.*) To avoid that, what sort of machine do you think could be adopted? In the first place, what machines are adopted in order to save the ladders?—There is no other machine in Cornwall but the man-engine.

2671. In your opinion could no other machine be adopted for the same purpose?—I think that there might be substituted for it what we call a gig, what we repair our shafts with. That might work in slides similar to skips. There is a canopy at the top, and it is square with a door opening on one side, and it hangs on the top like a swivel, and you may turn it about as you like.

2672. (*Mr. A. Bruce.*) Could you use such a machine in a shaft which was not perpendicular?—Where a skip would work that would work; it could work on the same slides.

2673. (*Mr. Holland.*) Would it not work in any ordinary shaft?—Yes, any drawing shaft.

2674. (*Mr. A. Bruce.*) Would you work this machine in the same part of the shaft as that by which you bring up the ore?—Exactly the same part of the shaft.

2675. Could that be done without interfering with the delivery of the ore?—For the time that the men were going up and down they could not draw the stuff.

2676. Would there be time enough for the delivery of the ore after allowing for the time taken up by the men?—In most mines the whole of the time is not fully occupied in drawing. If the shaft was not sufficient to discharge the stuff and the men, there could be another shaft to do it.

2677. (*Chairman.*) What would be the cost of one of those cages?—It could be made for about 15*l.*

2678. (*Mr. A. Bruce.*) The main expense would be the rope, would it not?—The same gear would do for both.

2679. There would be a little more wear and tear of the gear, that would be all?—Yes.

2680. (*Chairman.*) What should you say would be the cost of such a contrivance per day, for sending down 100 men; how much coal would it cost per day?—I should not think that it would exceed one shilling.

2681. (*Mr. A. Bruce.*) Have you ever seen that contrivance in use?—No, not in this country.

2682. Have you ever heard it recommended to any agent?—Yes, I have heard it recommended hundreds of times.

2683. Have you ever heard any good objections to it?—I never heard any good objections to it.

2684. What objections have you heard to it?—The men when it has been recommended to them, have said, "We would rather trust to the ladders;" but I believe that if the proprietors of the mines had entered heartily into it, it would have been done years ago; but they appeared to be rather indifferent to the matter.

2685. Then the objection came from the men, and the proprietors did not press the thing?—Yes.

2686. Have you ever known any change, however beneficial, approved by the men at first?—I do not know, they all fell very readily into the proposition as to having soup on coming from underground.

2687. (*Mr. Holland.*) Do you not know that the man-engine was just as vehemently objected to by the men?—I think it was.

2688. And did they not adopt it the first week that it was put up?—Yes.

2689. And now they will not go up by the ladders when a man-engine is there?—No.

2690. They will wait three or four hours for it?—Yes.

2691. (*Chairman.*) Will you state at what mine you were working before you came here?—At Wheal Uny.

2692. In that mine was any provision made for cooking the men's food?—We had a soup kitchen erected, with benches round for them to sit, and each man as he came from his work had a basin of soup

tendered to him directly, before he changed his clothes.

2693. What did he pay for it ?—Nothing. Mr. Fox paid for it. Mr. Fox said, "We will go on and try "it, and perhaps ultimately we shall charge the men "a penny a week to cover the expense, we shall see "what the expense is." And after some time, he said, "Never mind, go on."

2694. What was the effect of it upon the health of the men ?—They looked much better.

2695. Do you think that they would pay a small sum for it ?—I do not think that they would object to pay a penny a week, and I think that that would cover all the expense.

2696. (*Mr. A. Bruce.*) Surely it would not cover the expense of the soup ?—Yes, it would. That does not include firing or attendance.

2697. (*Chairman.*) You think that the men would be willing to pay a fair price for the advantage of getting some soup on coming out from their work ?—I think so, if they had it once.

2698. (*Mr. St. Aubyn.*) Do you know any mine where that has been tried ?—Dolcoath.

2699. Is it still continued ?—I think not.

2700. The men never paid a penny a week at Dolcoath, did they ?—I think not.

2701. When Mr. Fox had the management of the mine he supplied soup ?—Yes.

2702. And when he left it that was left off ?—Yes, I think so.

2703. But you do not know any mine where the men pay a penny a week and have their soup ?—No.

2704. You, however, think that it would be a good thing ?—Yes.

2705. And that the men would do so ?—Yes.

2706. How much would you give them for that money, a pint of soup ?—Yes.

A MINER examined.

2707. (*Mr. Austin Bruce.*) How do you judge when your time is up ?—We can just tell when we are tired, and can just judge by the candles and the work which we do ; that is as nigh as we can tell.

2708. Is there any signal or bell ?—Here, to grass.

2709. But you do not hear it down below ?—No.

2710. Are you fined if you come up before the time ?—Yes, sometimes ; not at all times.

2711. Would you be fined in case you arrived five minutes before the time ?—No ; I suppose not so nice as that.

2712. What is the smallest time for which you have ever been fined ?—We cannot tell ; there is no certain time for it.

2713. Who takes your time ?—The agent here.

2714. Is he always here when you come out ?—Not always.

2715. You generally fire a shot, I suppose, before leaving your work ?—Sometimes we do, and sometimes we do not.

2716. Do you not generally manage to try to do so ?—No, we do not always.

2717. Do you leave your work before the other men come in to relieve you ?—Yes, sometimes.

2718. What is the rule—are you generally out before the fresh men come in ?—We generally calculate to get up before they go down.

2719. Supposing you happened to fire a shot half an hour before your time was up, you could not do much work between that and the end of your time ?—No.

2720. What do you do in such a case ?—Sometimes we will come up.

2721. Are you fined then ?—Sometimes.

2722. Supposing you fired a shot half an hour before your time was up, where you could not work afterwards, would you venture to come to the top ?—We do so if it is very wet and cold.

2723. And you run the risk of being fined ?—Yes, we do.

2724. Have you ever suffered from your work underground ?—Not that I know of. I never had a great deal of sickness.

2725. Have you ever worked in bad air ?—Yes.

2726. How long together ?—I can hardly tell. I have been working underground a good while now; perhaps, two or three months together.

2727. At the end of those two or three months, would you feel worse than at the beginning of them ?—No, nothing more than at any time of working. I feel head-ache.

2728. Do you sleep well and eat well ?—Yes, I always do.

2729. Have you seen others suffer from it worse than you ?—Yes, in time.

2730. Have you seen men obliged to give up working ?—I have known men who have been obliged to give up working.

2731. We have heard something about a cough, and bringing up black stuff ?—Yes.

2732. Have you known cases of that ?—I do not know that I do much in that way, but men who work in poor air do so.

2733. You have never done so ?—No. I have brought up black stuff, but I never have much cough, unless I catch a cold, then I find that I get loaded on the stomach.

2734. How old are you ?—Twenty-five. I went to work underground at nine years of age.

2735. That, I suppose, was in turning a fan ?—No.

2736. What sort of work did you do at nine years of age ?—Tributer's work ; turning the borer.

2737. Holding it while the other person struck ?—Yes.

2738. How long did that go on ?—For several years.

2739. Then what did you do ?—Then I was man enough to strike.

2740. Then you began striking ?—Yes.

2741. When were you old enough to strike ?—Boys when they go underground like to learn to strike just as soon as they go underground, if the ground is soft enough for them to do any good. When they go as tributers, fathers generally take their own sons with them, and they bring them on to do work as quickly as they can.

2742. Did you go with your father ?—No, my father did not work underground.

2743. With whom did you go ?—Thomas Pugano was the first man that I went with.

2744. Did he pay you wages ?—I learned with him three months for nothing, to teach me to work underground ; then I had 15*s.* a month ; after that I had no father or brother to take me underground ; and I was small, and I could not get much working at the floors.

2745. How many mines have you worked in ?—In a good many about here. I have worked at South Phœnix, and South Caradon, and West Caradon, and Wheal Marshall.

2746. Have you found some better ventilated than others ?—In old mines there is poor air in places ; it depends a good deal upon how far the men work from any thoroughfare or draft.

2747. Did you ever complain to the agent of not having air enough in a bad end ?—I do not know that I ever did ; I have not worked much in an end ; I have worked a good deal upon tribute.

2748. Have you ever known men complain of not having air enough ?—Yes.

2749. Have you known them complain of that to the agents ?—Yes.

2750. What has been the answer generally ?—Then they will make an allowance for that ; they will put machines to throw air to them.

LISKEARD.

A Miner.

April 1862.

2751. Always ?—Almost always ; if the place is worth trying they will put some conveyance to throw air to them, and if not they will stop that place, and put the men in another place to work.

2752. What wages do you get, one month with another—3*l.* 10*s.* ?—Yes, I suppose so.

2753. (*Mr. St. Aubyn.*) Are you at tribute work now ?—No ; I am at tutwork sinking.

2754. You get the best wages that way ?—Yes.

The Commissioners then visited CRADDOCK MOOR *and* WEST CARADON MINES, *which they inspected ; after which they proceeded to St. Cleer, at which place they took the following evidence.*

A MINER (No. 1) examined.

A Miner (No. 1).

2755. (*Chairman.*) What mine do you work in?—West Caradon.

2756. How long have you been a miner ?—12 years.

2757. What do you work at principally ?—Tutwork.

2758. Do all the men work at tutwork in West Caradon ?—Yes.

2759. Are there any close ends there with the air not good ?—I cannot say.

2760. You have never worked in any ?—I have not been working in West Caradon more than about seven weeks.

2761. Where did you work before ?—At Crelake, which is at Tavistock.

2762. Did you ever work there when the air was poor ?—I did not work in any end, I worked in the stopes in Crelake, but there were some poor air ends there ; there was only one shaft in that mine.

2763. Are the men fined if they come up to grass before the time ?—Yes, if they make a practice of it, but once on a time I believe they forgive them.

2764. Have you worked in other mines in Cornwall ?—Yes.

2765. What other mines ?—In Fowey Consols and Par Consols.

2766. Is there a good changing house there ?—Yes.

2767. Do you know any men who have been affected from working in a bad end ?—Yes ; I have been affected in working at Par Consols myself.

2768. What was the effect of working there ?—It threw the rheumatism into my bones, and I was bad in the head.

2769. Did you get cold there ?—Yes.

2770. From what ?—From cold damp.

2771. What sort of thing is the cold damp ?—It makes the candle burn away up ; if a man is working hard and sweating, and stops a few minutes he gets chilled very quickly if it is in a cold place.

2772. The candle rises up, does it ?—Yes, the candle will run up terribly sometimes.

2773. (*Mr. Holland.*) Would your candle burn there ?—Yes.

2774. (*Chairman.*) Does that damp prevent the powder smoke getting away ? Were you blasting at that end ?—Yes.

2775. And did the powder smoke get away quickly ?—No.

2776. What did it do, did it hang ?—Yes, it hung about the place.

2777. How long ?—For a whole corps sometimes, I worked in one little mine, and there was plenty of circulation up in the level, but the smoke would come up six feet, and it was like a soller, it would rise no higher ; we were forced to give up working there, we could not work there at all.

2778. Did the men ever fall down before it ?—No.

2779. Were any means taken to remove it ?—No, the place was stopped working, they rose against it.

2780. The men would not work ?—No, we all of us gave up our place.

2781. How many were there of you ?—Six.

2782. Did any other men take to it afterwards ?—No.

2783. About how long ago is that ?—About three years.

2784. What was the effect upon you of working there ?—It affected me in my head.

2785. Did it produce giddiness ?—Giddiness and pain, and a beating in the head and heart, after six or seven fathoms I was forced to stop.

2786. How long did you continue to work in it ?—Four weeks.

2787. Were all the others equally affected with yourself ?—There was one not affected so much as the rest.

2788. (*Mr. Holland.*) Was your level in granite ?—No, in killas.

2789. (*Mr. Fulke Egerton.*) Did you ever feel much inconvenience from the dust ?—Yes, a great deal in the chest. I felt tied up in the chest and the breathing.

2790. (*Chairman.*) From what was the dust ?—From the hole in boring.

2791. Did you feel it in your mouth, or how did you know that it was from the dust ?—I spat it up, a great quantity of clots of nasty black stuff.

2792. Was not that powder smoke ?—No. I have been working in places where we have not shot at all, and have brought it away just the same.

2793. In what mine was the damp which you have described ?—We call the mine Scoble's, it is under the same company as Par Consols.

2794. Where was the dust which you spoke of?—We find it in every place where we work, not in one place only.

2795. (*Mr. Austin Bruce.*) Where are you working now ?—In West Caradon.

2796. Were you at Fowey before you came here ?—No, I was at Tavistock before I came here.

2797. How long were you at Fowey Consols ?—Six or seven years.

2798. Was it worse ventilated than other mines in which you have been ?—I think that the mine was ventilated pretty well, there are a great many shafts on, a new one was sinking for ventilation when I worked there last.

2799. Were the close ends well ventilated ?—Some were well ventilated, and some were driven a long way from any draught.

2800. Do you call a close end well ventilated in which you suffered in the manner which you have just described ?—No.

2801. Do you think that that could have been avoided ?—Yes, I think it could.

2802. Did you ask the agent to improve the air ?—We generally complain of having poor air when we have it, and try to have a machine to blow air to us ; sometimes we get it, and sometimes we cannot.

2803. What was the reason why you could not get it ?—I do not know, it might be done if they had a mind to put it for us.

2804. (*Chairman.*) Have you ever been refused ?—Yes.

2805. You have spoken to the agents, and they have refused to put it ?—Yes, they have refused to put it.

2806. (*Mr. Austin Bruce.*) How long is it since you worked in bad air ?—It is about three years ago since I worked in anything that was very bad.

2807. How have you managed to keep out of bad air during the last three years ?—I would not go in such a place.

2808. Were there people in the mines in which you have been working during the last three years, who were working in bad air ?—Yes.

2809. Did you know any of them ?—I cannot remember any by name now, I know that several worked in one mine. You cannot go in one mine

out of 20, or one out of 100 hardly, but there are some poor air places in it, hardly fit to work in.

2810. Are there any places in the mine in which you are now working, in which you think that it is dangerous to a man's health to work ?—I cannot say, I have not been over the other part of the mine.

2811. Have you for the last three years been working on tribute work ?—No, I have been working at tutwork two years, and about 12 months on tribute.

2812. Tutwork is generally more unwholesome than tribute work, is it not ?—Yes, a great deal more.

2813. Do you think that your health has suffered from the bad air in which you worked when a younger man ?—Yes, I am quite certain of it.

2814. How do you know it ?—When I worked in Par Consols the doctor told me that if I did not go away from where I was working, I should go into a consumption in less than six months.

2815. Did somebody take your place when you went away ?—Yes.

2816. You are a strong-made man ?—Yes.

2817. Was your health as good as that of most men ?—Yes, generally.

2818. Do you know what became of the men who followed you in that place ?—No.

2819. You do not know whether they had to give up too ?—No, I do not.

2820. How long have you been working ?—About 20 years.

2821. Should you say that during that time there had been an improvement in the mines ?—Yes, a great deal, a very great improvement.

2822. Do you think that the young men who begin to work now will have a better chance of keeping their health than those who began to work 20 years ago ?—Yes, a great deal better.

2823. For more reasons than one ?—There is a great deal more circulation now than there used to be when I went underground first.

2824. And is more care taken about drying the men's clothes ?—Yes, I seldom put up wet clothes myself.

2825. What is the deepest pit that you ever worked in ?—260 fathoms.

2826. How long did you take to mount that 260 fathoms ?—We used to ride in a man engine from the 240 fathoms.

2827. (*Chairman.*) Was that at Fowey Consols ?—Yes.

2828. (*Mr. Austin Bruce.*) You had only 20 fathoms to climb ?—Yes.

2829. What is the greatest height that you ever had to climb on the ladder ?—265 fathoms.

2830. Where was that ?—It was at Dolcoath, there was a man engine there, we used to ride from the 190 fathoms.

2831. When you had 260 fathoms to climb, how long did it take you ?—About an hour and a-half.

2832. Which was the hardest, that hour and a-half or an hour and a-half working ?—The hour and a-half climbing.

2833. Do you think that it took out of you as much as two hours of work ?—Yes, as much as all the four of working, I should think.

2834. Did you work fewer hours in consequence of the length that you had to climb ?—No.

2835. Your time was for eight hours all the time, was it ?—Yes, we were obliged to work eight hours to get a living for our families.

2836. Did that tell upon your health ?—No, I cannot say that it did.

2837. You were working in a healthy place then ?—Yes, we were working in better air there.

2838. If you had had that climbing over and above a bad close end, what would have been the consequence ?—I should not have been able to do it at all ; you feel it in your legs directly.

2839. Do you think that you could do the same day's work in eight hours when you had to climb 260 fathoms by a ladder ?—Yes, we always do the same work.

2840. (*Mr. Holland.*) In fact you were working 10 hours ?—Yes.

2841. (*Chairman.*) Do you think that you were as well able to do the work ?—No, I do not think that I was so well able to do it at all.

2842. (*Mr. Austin Bruce.*) After doing that day's work, and climbing 260 fathoms, were you ever so tired as not to be able to sleep or to be thrown off your feed ?—Yes, many a time ; I carried my parcel underground, and brought it home as I carried it, scores of times.

2843. And did you find others the same ?—Yes.

2844. You think that a man has a chance of a longer life who works in a pit where there is a man engine ?—Yes, if it be a deep one.

2845. What do you think is the amount of climbing which a man can do over and above his work without injury to his health ?—About 40 or 50 fathoms we do not take much account of, but if we be working in bad air we then feel it ; when we climb 10 fathoms we feel it in our legs directly.

2846. (*Chairman.*) But in good air, what depth could you climb without injury to your health ?—In good air we do not take any notice of it.

2847. Fifty fathoms ?—Fifty or 60 fathoms.

2848. Would climbing 200 fathoms be fatiguing, even if the air was good ; would you suffer from it ?—It would be a little fatiguing.

2849. (*Mr. Holland.*) What is a fair price per fathom for driving ?—It would depend upon the ground ; there are different sorts of ground, 10*l.*, 20*l.*, 30*l.*, and 45*l.*

2850. Supposing that you took some tutwork for driving, the price of which was, say, 5*l.* a fathom, how much more would you charge per fathom if you had to climb 260 fathoms to get from it ?—I do not know ; I do not see that it would make any difference in the price at all.

2851. You would prefer working in a mine where you had not to climb, to working in a mine where you had to climb ?—Yes.

2852. Would you not have more wages for climbing the extra distance ?—We ought to have more, but we are not allowed a halfpenny more wages.

2853. (*Mr. Austin Bruce,*) Do not the men go more readily to pits where there is not much climbing than to pits where there is much climbing ?—Yes, every man, where there is a little shallow level to drive, or a rise or a winze to sink would jump at it directly if he could get into a shallow place rather than a deep one.

2854. (*Chairman.*) Is there any difference in what is paid for driving in a shallow or in a deep mine ?—No difference at all.

2855. It is only according to the hardness of the ground ?—Yes.

2856. (*Mr. Austin Bruce.*) In the course of your life have you been attended by a doctor occasionally ?—Yes.

2857. Were you always attended whenever you were ill ?—Yes.

2858. Without paying ?—Yes ; we pay our money at the mine ; so much is kept out every month for the doctor.

2859. And the doctor attended you when you were ill, or when you had been hurt by an accident ?—Yes.

2860. When you were off your work, did you receive anything from the club ?—No, I never received anything from the club in my life.

2861. They do at some pits, do they not ?—Not for sick pay, unless it is at St. Blazey, under Squire Trefry, we have sick pay there ; but in other mines I never heard of sick pay except for accident.

2862. You had your medicines ?—Yes.

2863. But nothing else ?—Nothing else.

2864. How long have you ever been ill at a time ?—Four months.

2865. What was that owing to ?—Typhus fever

LISKEARD.

A Miner (No. 1.)

17 April 1862.

and inflammation in my stomach and pipe. I was then working at West Caradon, about seven years ago.

2866. (*Mr. Holland.*) How much did you pay to the club?—Ninepence a month.

2867. (*Chairman.*) Supposing you were working in an end with poor air, and you were sick from that, would you get the club money?—No.

2868. Only for accident?—Only for accident.

2869. Some of the miners did not like giving evidence before us; what do you suppose this arose from?—A great many of them say that they are afraid that they will get turned away from the levels, that it would be known if they had said anything against the mines, and that they would be turned away.

2870. If they were turned away, would they get employment elsewhere?—I should think so, if there was any employment to be had.

2871. Would other agents take them if they were turned away?—I cannot say about that.

2872. (*Mr. A. Bruce.*) Do you think that there is any danger of a man being turned away in consequence of his giving evidence if he gives it fairly?—I do not know, in fact I do not care, because if I have not work at one place I must have it at another.

2873. Have you ever known men turned away for similar things?—I never knew a case of this sort before.

REFORM CLUB PALL MALL

The witness withdrew.

A MINER (No. 2) examined.

A Miner (No. 2).

2874. (*Chairman.*) What mine do you work in?—West Caradon now.

2875. What mine did you work in before?—South Caradon.

2876. For some time?—Yes; I worked at South Caradon for about six years this last time. I have worked there two spurs, and I have been at West Caradon a little more than two months since I have left South Caradon.

2877. Is West Caradon as well ventilated as South Caradon?—I do not think there is much difference.

2878. Have you ever worked in a bad end?—No; I worked on tribute generally, I have worked upon tutwork for a few months, but not very much; but I have been acquainted with the proceedings of persons who have worked in ends.

2879. In your own experience you have not worked on tutwork in ends with poor air?—No, I have not myself.

2880. Why do you prefer tribute work?—Because sometimes there is a greater chance of getting more money upon tribute than there is upon tutwork.

2881. But sometimes you are a long time without any?—Yes.

2882. There you are allowed sist money?—Not unless we get it. I have worked as much as two years, and have not received from the mine more than about 40*s.* per month right on.

2883. Then another year you have done better?—Yes; perhaps, upon the average, you do as well or better than they do upon tutwork. Then again on tribute we generally work by day.

2884. (*Mr. Austin Bruce.*) Have you ever suffered in health?—No, not very much; I do not know that I have.

2885. (*Chairman.*) Do you know of miners who have suffered in health?—Yes, I believe that I have known several who have shortened their days by working in close places. We calculate so. My father was a miner, and he died at the age of 55; he considered that he died by what we call the miner's complaint, by working in close places.

2886. (*Mr. Austin Bruce.*) Had he been suffering long before he died?—Yes, he was obliged to stay home from labour, I think, 16 or 17 months. There are several in the village now who are suffering from some complaint, and it is calculated that it is on account of working in poor air, and so on, in powder smoke, and so on.

2887. (*Chairman.*) Could we see those who are now suffering?—I cannot tell that. I cannot say that I know any person who is laid up at present.

2888. (*Mr. Austin Bruce.*) Had your father often to give over work before he died in consequence of his illness?—No, not more than just perhaps a day or so in and out, his breath being bad, and so on. The least little cold would affect the breath so that he was obliged to stay at home.

2889. Have you ever been working at all in a bad close end yourself?—I have not worked in an end, but I have worked in close places, that is, in a rise in the back; the place that I am now working in, is rather a closeish place.

2890. Have you complained of the want of sufficient ventilation?—No, we have not complained; I do not know that it is of much service to complain. I do not see how they can ventilate it.

2891. Why not?—One reason is, that it would not pay. I am working now in a pitch, and the captains give us two-thirds of the pound, and it will hardly pay. 13*s.* 4*d.* out of a pound is as much as they can give, as they are allowed to give by the mining gentlemen.

2892. (*Chairman.*) Do they give that because the air is not good there?—No, it is not on that account.

2893. (*Mr. Austin Bruce.*) Are you working now at that rate?—Yes.

2894. Have you been long working at that rate?—The last two or three months; it is going on for three months.

2895. How has it answered?—Not at a very great rate; perhaps we may have got 4*l.* a month. Generally speaking, when we are working in a close place, that is to say, where the air may be tolerably good but yet close, there being no thoroughfare, the agents, I consider, do not make allowance enough (and it is so considered by the men generally) in a close place; the smoke remains a long while in those places. Sufficient difference is not made between the price given for a place where there is a thoroughfare and for a place where there is none; and for the price which the agents give, we are obliged, if we have a mind to get any money to bring home to our families, to rush into the work again almost as soon as we shoot.

2896. (*Chairman.*) So that in consequence of the smoke not getting away you are obliged to go in too soon?—Yes; and powder smoke is a thing, I fancy, which chokes up the pipes as much as poor air when we are obliged to rush into it.

2897. (*Mr. Austin Bruce.*) You say that men are unwilling to work in small close places?—Yes; they are unwilling to do it, bnt they are obliged to do so if they are minded to get a livelihood.

2898. Why are they obliged?—Because they must have that or stay unemployed, perhaps, a month or so.

2899. But there are fewer men who will go there than into better ventilated places?—Yes; none would go there if they could help it.

2900. Does not that lead to the master paying a higher rate to the men who go into ill-ventilated places than to those who go into better ventilated places?—No; they do not calculate upon getting anything more.

2901. (*Chairman.*) The agents can always get men to go into those places?—Yes, and oftentimes men are glad to go there rather than stay out of employment; but they are not remunerated better, and they can hardly get so much money there because they have not the chance; they cannot work so much, because the agents do not give a better price for a place which is not very well ventilated than they do for a place

LISKEARD.

A Miner (No. 2).

17 April 1862.

which is properly ventilated. They can always get men in our neighbourhood now. There are always men at hand willing to go anywhere and work.

2902. (*Mr. Austin Bruce.*) What is the deepest shaft in which you have ever worked without a man engine ?—I have never worked more than these two mines ; about 140 fathoms is the deepest that I ever worked in.

2903. How long did it take you to climb up the 140 fathoms ?—We calculate about half an hour ; we can do it quicker than that, but in walking through the levels, and having, perhaps, a minute or two to fetch our breath, it will take half an hour and upwards. A person taking it pretty steadily will take nearly three-quarters of an hour to climb up 140 fathoms, to take it moderately.

2904. Did you find it very exhausting ?—Yes, very.

2905. Do you think that it took much out of you ?—Yes.

2906. As much as a quarter of a day's work ?—Yes, I should think so. It would do more injury than a quarter of a day's work ; and in these mines here if a person is working at 140 or 150 fathoms, and is working very hard ground, generally speaking, we have to carry all our tools, and sometimes we have a very heavy sling, perhaps 40 or 50 lbs. weight, upon our shoulders, to carry that distance.

2907. (*Chairman.*) I suppose that if means were provided for ascending you would be very glad to adopt them ?—Yes, quite so.

2908. You would not prefer the ladders ?—I never saw any man-engine, but I have heard individuals speak of it who have been accustomed to ride up and down, and they say that it is a very great benefit in deep mines.

2909. (*Mr. A. Bruce.*) I suppose that wherever you have worked you have always had a good drying place to change your clothes in ?—No, I do not see that I can boast of that. At South Caradon now it is pretty fair ; but I have been at West Caradon, and I do not consider that it is very much there.

2910. Have you ever worked in a mine where there was no warm place to dry your wet clothes, and in which you could change your clothes ?—Yes.

2911. What was the effect of working in such a place ?—I often caught cold, and so on. At South Caradon, about some ten years ago there was no dry at all. It is true that when we came up with our clothes wet, we were allowed to carry them down to the blacksmith's shop, and hang them over the forge which had been working during the day, and it was naturally warm ; and if our clothes were dry, well and good, but, if not, we must put them up as they were.

2912. That very much increased the risk of ill-health ?—Quite so.

2913. (*Chairman.*) Do you think that the miners are quite independent of the agents ?—No, I do not think they are at all.

2914. They are afraid of offending the agents ?—Yes, where men are so plentiful as they are in our neighbourhood, and I suppose, through the county at large, there are a good many individuals who hardly know what to do to get a job of work.

2915. With respect to your pay, it is always one month behind, is it not ?—Yes ; upon tutwork it is one month behind, but upon tribute it is as they can sell the ore. At West Caradon we must work six months before we can have pay-day upon the ore that we put in ; however, if the agents think that we have got money coming they allow us some subsist, but upon tutwork they always keep one month in hand.

2916. Is that general in this neighbourhood ?—Yes, it is general through the county, I suppose.

2917. So that a man who has been out of work gets nothing for two months ?—No, unless the agent will allow him 20*s.* to mocksist or subsist. "Sist" is what we term the general thing, and "mock" means lent.

The witness withdrew.

A MINER (No. 3) examined.

A Miner (No. 3).

2918. (*Chairman.*) What mine are you working in ?—Caradon Consols.

2919. At tribute or at tutwork ?—Tutwork.

2920. How long have you been there ?—Two years nearly.

2921. How long have you been a miner altogether ?—About 15 years.

2922. What other mines did you work in before ?—I worked in Polgooth before I came up to this part of the country, that is down at St. Austell.

2923. Is Polgooth the deepest mine that you ever worked in ?—Yes.

2924. What is the depth of Caradon Consols ?—70 fathoms now.

2925. Is that a young mine ?—No, it has been working a good many years.

2926. Are there any close ends with poor air there ?—No, not now ; there have been in the summer time too many close ends.

2927. Have you ever felt any ill effects from close air ?—I do not know that I have much.

2928. What is the difference as regards the air between summer and winter ?—The air is a great deal closer in the summer time.

2929. In blasting does the smoke get away quickly at the ends ?—No, not now, it will lie there now.

2930. Is there any damp ?—No, not now, at this time of the year, not in the winter part of the year.

2931. But in summer is there any ?—I think there is a little in the summer time.

2932. Have you never suffered in your health ?—No, I have been in the shaft over there these last 12 months ; and if there is any air at all in the mine it is in the shaft generally.

2933. Have you been working in the last 12 months at any end ?—I am now in an end ; our shaft is down now, and we are driving.

2934. Do you know any miners who have suffered from working in poor air ?—I do not know that I do about here now ; there are several miners here who are bad, but whether it is owing to the poor air or not, I do not know.

2935. What is the matter with them ?—I am sure I do not know ; it is what they call about here, the miner's complaint, I believe, that is to say, in the lungs and the liver, and one thing and another. I do not know exactly what it is.

2936. Are you a single man ?—No.

2937. Do you live here ?—Yes.

2938. (*Mr. A. Bruce.*) You have never been ill yourself ?—No.

2939. (*Chairman.*) Have you ever climbed any great depth of ladders ?—No, not lately ; not the last ten or dozen years.

2940. (*Mr. A. Bruce.*) What was the greatest height which you had to climb ?—230 fathoms.

2941. By a ladder ?—Yes.

2942. How long did that take you ?—I am sure I do not know, it would take an hour or an hour and a half, I suppose, if you went along smart.

2943. An hour and a half coming up ?—Yes, I suppose so.

2944. And how much going down ?—Three-quarters of an hour, perhaps, or just like that ; I cannot tell exactly to a quarter of an hour.

2945. Is an hour of climbing as bad as two hours of work ?—Yes, worse I think, that is in an upright shaft ; a great many shafts in this country are underlay, and that is not such hard work as when it is upright.

2946. Were you ever so tired as not to be able to sleep at night ?—I have been.

2947. After what sort of work ?—When the air has been close and you feel your legs aching.

LISKEARD.

A Miner (No. 3).

17 April 1862.

2948. Where was that?—Over at Caradon Consols the last summer.

2949. What sort of a place were you working in?—In the shaft then.

2950. Sinking the shaft?—Sinking the shaft.

2951. Was there a want of sufficient air?—Not there, not last summer.

2952. What was the cause of your suffering?—The poor air; I felt weakness in the legs; I do not know that I felt bad.

2953. Why was there poor air?—Because there was no circulation.

2954. Why was there no circulation?—Because we had only one shaft.

2955. Was nothing done to convey circulation?—Yes; we had a machine there.

2956. At work?—Yes.

2957. That was not enough?—No; it was not at the time.

2958. Do you know any reason why every shaft might not be sufficiently ventilated, if proper care was taken?—I do not know; I do not think that one shaft is enough in a mine, there ought to be two.

2959. I thought you said that you were working in a shaft last summer?—Yes.

2960. You were sinking a shaft?—Yes; we were then.

2961. Is there any reason why men sinking a shaft should not always be supplied with sufficient air?—There is a reason that it might be better.

2962. (*Chairman*). Where was the machine fixed?—About eight fathoms down from the surface.

2963. Was the shaft divided?—Yes.

2964. (*Mr. Holland.*) Did that division go to the bottom?—Yes.

2965. Then why was not there good air at the bottom?—Because there was no circulation anywhere in the shaft, and anywhere in the mine.

2966. (*Chairman.*) How was that machine worked?—With an engine.

2967. How soon was that put on after complaints were made about the poor air?—I do not know.

2968. Was it put on in consequence of complaints about the poor air?—Yes.

2969. And did that have the effect?—That would give some air; it made it a little better.

2970. Has the mine only one shaft now?—It has only one shaft now where we are working to.

2971. (*Mr. Holland.*) Is there no adit?—No, our shaft is divided from grass all the way down to where we are working now.

2972. (*Mr. Austin Bruce.*) How many men are working in that shaft?—Six men, there have been nine.

2973. How many were there at a time in the shaft?—Three.

2974. Did all three suffer as you did?—Yes.

2975. Did you make any complaint to the agent?—Yes, we told him that it was very poor air, and that we could not work there.

2976. What did he do?—He then had this machine.

2977. Were you then able to work better?—A little after that.

2978. It was not good enough?—No.

2979. Did you then complain again?—Yes. He cased the shaft close and made it air-tight; he thought that it would throw air better by being air-tight, so that the air should play through any place; it was like two shafts.

2980. Did that improve the air?—When he had done a little the winter came in, and we had then better air, so that we have had no trial of it yet; this summer will be a trial for it, I suppose.

2981. Are you still sinking there?—No, we have stopped sinking now, but we are driving.

2982. You are driving an end, I suppose?—Yes.

2983. But the ventilation is good, is it?—Yes, it is very good air now.

2984. (*Chairman.*) The candle burns well?—Yes, now.

2985. (*Mr. Austin Bruce.*) Where you are you have a good house to change your clothes and get them dry, have you not?—Tolerably well now.

2986. Have you ever been in a place where there was none?—Yes.

2987. Where?—Over at South Caradon; that is years ago; they have now better convenience there than they had then.

2988. Did you change your clothes when you came out?—Yes. When I have gone to mine I have gone over there in the afternoon in cold weather when there has been a little rain, and I have come up and put on my clothes when they have been frozen, at 10 o'clock, and my trowsers would stand up as stiff as a stick.

2989. That is to say, they were wet and were not dried, and they froze?—Yes; that is years back.

2990. Do you think that a man would do that often without some bad consequences?—No; I feel the pains of it to this day.

2991. There is not much of that now, is there?—No, I believe not. I do not work there now.

2992. But anywhere?—Not that I know of.

2993. You know, I suppose, what is going on at a good many of the mines about here?—We call round sometimes. We change in the boiler-house now at our mine.

2994. You know most of the mines about here?—Yes.

2995. Are there dries at all of them?—Yes, chiefly now, I believe.

2996. That was not the case when you were a boy, when you began working, say 20 years back?—No.

2997. (*Mr. Holland.*) Are there not a great many mines without dries now?—There are dries among these mines now.

2998. Not at all mines?—No, not at the whole of them. There is no dry at our mine at Caradon Consols; we change upon the boiler there; it is warm.

2999. There are a great many young mines which go on for several years before they get any place to dry?—Yes, a number of years.

3000. (*Mr. Austin Bruce.*) That cannot go on without injuring the health of the men?—No, I should not think it could.

3001. (*Mr. Holland.*) Are a great many miners rheumatic?—I am myself.

3002. You know a great many who are rheumatic, do you not?—A good many, I believe, have the rheumatics.

3003. Is it not a very common thing?—Yes, I believe it is.

3004. Is it not, to a great extent, owing to putting on damp clothes?—Yes, I believe so. I believe that that is one cause. I first got it with cold, and damp clothes put on.

3005. Do you often catch cold?—Yes.

3006. Does it affect your chest?—Yes.

3007. Have you any cough now?—No, not now.

3008. You have not a permanent cough?—No.

3009. Is your stomach is good order? have you a good digestion?—Yes, I believe that now I have.

3010. Do you not know many miners with a very bad digestion?—No, I do not now.

3011. (*Mr. A. Bruce.*) Can you, as a working miner, see anything which can be done in these mines to improve the health of those who work in them?—Yes, improvement can be made.

3012. What improvement would you suggest?—The improvement is, that in these mines where there is only one shaft there ought to be another; there ought to be two shafts, and then a hole from shaft to shaft to go down, and then there would be better air.

3013. Anything else besides better air?—I do not know. If a man has good air and a good price he would get better wages.

3014. (*Chairman.*) Do you know what distance there ought to be between one shaft and the other?—I do not know; I do not believe that there is much nicety in that for a few fathoms.

3015. If the men come to the surface before the time is up are they fined?—They are sometimes, if

they make a practice of it, I believe, that is to say, coming up night after night, or day after day, before the time; perhaps the first time they get a scolding, and then the next time they will perhaps be spaled

3016. Are you bound to stay down till the next corps come down to relieve you?—We come away, I believe, chiefly before the time; we meet them somewhere, perhaps, on the road in the shaft, somewhere going up and down the ladders.

3017. If you meet them in the ladders do you get on to one of the levels, or how do you manage?—There are places in going down to stop, and you stop there if you meet. Sometimes we meet them up at grass.

3018. Do the men ever stand on the ladders waiting if it is before the bell rings?—Yes, they lie about rather than go in to get fined; they would rather lie about anywhere.

3019. So that they stand on the ladders?—They stand or lie about on the levels or anywhere, shivering with the cold sometimes.

3020. That, I suppose, is if they have blasted?—Yes; if they have shot they come away up when they have done their corps.

3021. And they must not come to grass before the bell rings?—They must not.

3022. Therefore they wait on the ladders and about the ends?—Yes, anywhere. If it is dark they will come up and lie about anywhere rather than be spaled, as we call it.

The witness withdrew.

A MINER (No. 4) examined.

3023. (*Chairman.*) How old are you?—I am in my fiftieth year.

3024. How long have you been working in a mine?—About 16 years now.

3025. Have you ever suffered from it?—I never felt very much from it as yet.

3026. Are you working now in a mine?—Yes.

3027. Which mine?—Craddock Moor.

3028. Have you ever worked in an end with bad air?—No; I never worked in an end in my life.

3029. Have you been always working at tribute?—No; my work is filling the kibbles or the skips.

3030. (*Mr. Austin Bruce.*) Are you working now?—I have been at work to-day.

3031. Eight hours?—Yes.

3032. Can you do your work heartily?—Not so heartily as I used to do; I find that my age is different; I have caught a cold in rather a damp place, and have felt cold rather.

3033. Have you any cough?—Yes; a little, not much.

3034. (*Mr. Holland.*) Have you a good deal of phlegm?—No, not much.

3035. Does your heart beat much?—Sometimes it beats pretty much; it is beating now rather.

3036. (*Chairman.*) How many fathoms have you to climb?—All sorts; I go from the 96 fathoms, that is the bottom of our mine, and then I take it all through from the bottom to the top; sometimes to the 40th fathom, is the shallowest that I work, from the 40 fathoms to the 96 fathoms.

3037. (*Mr. Austin Bruce.*) How do you find yourself after climbing 96 fathoms?—I find myself weary then after working eight hours.

3038. Do you ever find that it prevents you from sleeping or enjoying your dinner?—No, it does not prevent me from sleeping at all; I sleep rather too sound, if there is any difference.

3039. Does it ever prevent you from enjoying your food?—Yes, sometimes, it is with the climbing; we have very hard work.

3040. Have you a good place to change your clothes?—Yes, very good.

3041. Have you ever worked in a mine where you had not a place to change your clothes in?—No, I never did that.

3042. You began late in life to work?—Yes; that sort of work.

3043. (*Chairman.*) What did you work at before?—In the woods and plantations, that was my rearing up, I had 21 years at it, and I should not care if I had another good situation now.

3044. (*Mr. Austin Bruce.*) You would rather be above ground than under ground?—Yes, at my own calling, that was my calling.

The witness withdrew.

A MINER (No. 5.) examined.

3045. (*Chairman.*) What mine are you working in?—West Caradon mine at present, the last five months, that is all.

3046. Where did you work before?—In the Phœnix mine for three or four months.

3047. What work did you work at, tutwork or tribute?—Tribute at present, but at the Phœnix I was on tutwork end.

3048. Did you ever work in poor air?—Yes, a little, not much.

3049. You say not much, did you give it up?—Stoping was the chief work that I worked at there; we stoped the ground, and it gave better ventilation for the air. On account of the obstruction being in the middle, the air passed up and down through the place; it is not like driving a tutwork end, for I have worked in a tutwork end.

3050. It improved it?—Yes. There was a level driven over and under, so that we put a hole right through, so that in going up it caused a ventilation when we got through. The ground being fair it did not take so long to get all through as if the ground had been hard.

3051. How long were you working while the air was poor?—About four or five months.

3052. During that time did you suffer from it at all?—Yes.

3053. In what way?—In my stomach, and when I climbed the ladders I felt my legs trembling, just like palpitation.

3054. What depth had you to climb in the Phœnix mine?—150 fathoms then.

3055. How long did it take you to go up?—We generally calculate about half an hour, allowing for time to draw breath and just to refresh ourselves a little.

3056. You never suffered in health from working?—No, for no great length of time.

3057. (*Mr. Austin Bruce.*) How old were you at that time?—About 24.

3058. I suppose that a man at 24 suffers less from bad air than a man at 34?—Yes.

3059. Is it good air where you are working now?—Yes, very good indeed.

3060. (*Chairman.*) You come up whenever you like, do you not?—We are not allowed to be up before two o'clock, that is as a custom, if we do we get fined.

3061. Are you fined even for tribute work?—There is not much said perhaps for a time or two, but the captain is generally on the look-out.

3062. (*Mr. Austin Bruce.*) Do you think that the life of a miner is a healthy life?—Not in the least.

3063. What would you do to make it healthier?—I believe that there are a good many ways to make it healthier at times. Some places, I believe, cannot be made better while they are in operation; but in some places a level is driven a long way, and then there is no communication from the level above, which is driving over it; perhaps the ground is poor, and the

LISKEARD.

A Miner (No. 5).

17 April 1862.

agents do not think, I suppose, that there is a need of putting a winze through; but they may happen to meet with a bed of ore, and then they put a winze through, and then it makes the ventilation good again.

3064. (*Chairman.*) Have you ever seen any artificial means of ventilation?—Yes, what they call air fan machines.

3065. How are they worked?—They are turned with a hook handle.

3066. By a boy?—Yes.

3067. (*Mr. Austin Bruce.*) Then you think that with a little more attention to ventilation the miner's life might be lengthened?—Yes.

3068. Does anything else occur to you?—I believe that the greatest failure is, that the wages are not enough; a man is not allowed enough according to the place in which he works, in my opinion. When a man is working in a poor air place, he is not allowed so much in accordance with what he ought to do.

3069. Would higher wages give him better health?—With higher wages he would not want to rush so quickly into the smoke; when a man has a slight price, he is obliged to rush in quicker than he would if he had more wages.

3070. If there was a good current of air the smoke would be carried away quickly?—Yes.

3071. (*Mr. Holland.*) Would not that be the same thing as raising his wages?—Yes.

3072. With less loss of time he would earn more?—Yes.

3073. I think you said that your stomach had been put out of order by bad air at one time?—Yes.

3074. How long did that illness last you?—Not particularly long; just a week or two. I felt uncomfortable in working; I could not work as well as if I had been working in good air.

3075. How long were you working in poor air before you felt it make you poorly?—About three or four months.

3076. Did your appetite fall off?—Yes.

3077. Had you head-ache?—Yes.

3078. (*Chairman.*) How did you know that it was poor air?—Because when I went to sit down for my comrade to work I got sleepy; that is one reason.

3079. (*Mr. Holland.*) You got sleepy in the mine?—Yes.

3080. You had a difficulty in keeping yourself at your work?—Yes.

3081. Did your legs tremble under you?—In climbing the ladders.

3082. Had you a throbbing of the head?—Yes, heart-beating.

3083. More than in good air?—Yes.

3084. Much more?—Yes.

3085. Did the candles burn dim?—Yes.

3086. Cannot you perceive the air to be bad when it is not enough to make the candle burn dim?—Yes.

3087. You still feel it?—Yes, what they call the cold damp.

3088. That does not affect the candle much?—No, it makes it burn very bright indeed.

3089. You mean that it increases the size of the flame, but it does not increase its brightness, does it; it makes the flame larger?—Yes.

3090. But not brighter, does it?—Not very, it makes more difference in the size of the flame.

3091. (*Mr. Austin Bruce.*) You want more air and, higher wages, and what else to make you perfectly healthy?—I do not see that much more can be done beneath the surface than that, that is the greatest thing that miners require, I believe.

3092. (*Mr. Holland.*) Would you like some mode of getting up from the mine instead of climbing?—Yes, that is one thing; I did not think of it at the moment.

3093. (*Mr. Austin Bruce.*) And you would like a good place in which to dry your clothes, I suppose?—Yes.

3094. (*Chairman.*) The men only work eight hours, do they?—Eight hours.

3095. Are you married?—Yes.

3096. What family have you?—One child.

3097. What amount of butcher's meat are you able to purchase in a week?—At the gettings which we are allowed, we cannot afford more than about 3 lbs. or 3½ lbs.

3098. Is that meat made up into a pasty, or is it taken separately?—It is done all sorts of ways.

3099. (*Mr. A. Bruce.*) Do the young women learn cooking?—Yes, some of them.

3100. (*Mr. Holland.*) Are they pretty good cooks?—Yes; middling, I believe. I have heard that the Cornish cooks excel the most in England for putting a little joint the furthest, as we call it. I would say that I worked at the Phœnix mines, and we had to climb 200 fathoms below the adit; that is 14 fathoms more. Sometimes a man will come away, perhaps, a little sooner by that means, because he had to climb all the way, and it would take him longer to go up, and sometimes we have been very wet. When we got to the surface it would not be time for us to go in to our dry to change, and we were obliged to stop out, and caught colds; and I believe that very often it brings on diseases.

3101. (*Chairman.*) Standing on the ladders?—Yes, and hiding in holes out of the agent's sight; and it is very cold and draughty in some places.

3102. (*Mr. A. Bruce.*) Why did you leave your work before the proper time?—Because we have no guide to go by as to the time more than our candles.

3103. Is not that enough when you get some experience?—Sometimes the candles are not so good as at other times.

3104. How did you know that you were not in proper time when you got to the top? Had not you the same means of knowing at the bottom as you had at the top, whether your time was up or not?—We saw the men who were engaged in landing the stuff, and inquired; that is the information which we get chiefly.

3105. What remedy would you suggest for that?—I am sure I cannot tell much about the time, but with regard to helping men climb up, I think that the man engine is the best remedy that I know of at all.

3106. Should a man-engine be put in every shaft?—No.

3107. Only in the deep ones?—Only in the deep ones, and in some a good deal of trouble would be required to put a man-engine. In the Phœnix mine, for instance, it might be a good deal of trouble, because in one shaft it is downright and on the lay, and in the other it is downright. In some mines again the footways are put in the same shaft where they wem all the stuff, making it very dangerous for a man to pass up and down.

3108. Did you ever know of any accident?—Yes.

3109. Of what sort?—I do not know that I have heard of a man being killed, but some have been injured by the chain breaking when men were going up; some were rather careless, and being rather behind time they wanted to make haste, and thought that they might just slip up in a certain place, and the chain has broken, and the stones have come down out of the full waggon as it was passing down, and have struck them, but not seriously. But it might be better if the footways were in a separate place without any communication with the wem. The kibble is very heavy with the waggon; it goes from side to side, and would smash everything it came in contact with. The mine in which I work now, I believe, is very good for that; there are so many communications, exceptional shafts.

The witness withdrew.

Adjourned to Saturday next at half-past 10 o'clock, at Liskeard.

Saturday, 19th April 1862.

PRESENT :

The Right Hon. Lord KINNAIRD, K.T.	H. AUSTIN BRUCE, Esq., M.P.
The Hon. A. FULKE EGERTON, M.P.	JOHN ST. AUBYN, Esq., M.P.
NICHOLAS KENDALL, Esq., M.P.	P. H. HOLLAND, Esq.

THE RIGHT HON. LORD KINNAIRD, K.T., IN THE CHAIR.

Mr. CHRISTOPHER CHILDS examined.

3110. (*Chairman.*) I believe that you are a solicitor ?—I am.

3111. And you have the management of some properties ?—I have.

3112. The Commissioners wish to know whether a proprietor in granting his sets of ground for a mine could make any provisions with the lessees that they should provide proper accommodation for the men in the way of changing houses above ground ?—Decidedly so.

3113. Do you think that it would be the interest of the proprietor to do so ?—I should hardly, perhaps, use that expression ; I think that it would be the interest of the adventurers themselves to provide proper accommodation.

3114. Would it not be to the advantage of a lord to make some provision by which the health of the miners would be attended to, in order that the expense of poor rates, which would fall upon him should not be increased ?—If you put it in a pecuniary point of view, I should say that it is not of any consequence to him.

3115. You do not think that in consequence of the miners being disabled, either by accident or by bad health, a greater number are put upon the parish, and thereby the poor rates are increased ?—The poor rates of that particular parish may be increased ; but perhaps your lordship is aware that the owner of the soil, as lord, is not liable to be assessed for the relief of the poor, because there is a sort of duplex reservation in the sets which enables him at any time to require rates to be paid by the adventurers themselves, or to relieve them from it as he thinks proper. A relative and friend of mine has required me in the granting of sets to reserve, in the first instance, a portion of the memorial, which is called a dish or dole, with an alternative clause, which he, by notice, can bring into operation, determining the reservation in kind, and providing for a monied payment instead. The reservation in kind is liable to be assessed to the relief of the poor, the reservation in money is not; his object being to compel the adventurers to pay something at least in aid of the rates of the parish.

3116. Supposing that a mine is abandoned, and the company carrying it on is wound up, on whom then falls the burthen of supporting miners, whose health may have suffered in that way ?—That is a question which bears on the poor laws generally I take it. For upwards of twenty years I have practised as an advocate at our quarter sessions, and as such advocate I have been frequently engaged in appeals, and have become well acquainted with the whole question of assessment in this county. The burthen of the maintenance of the poor must, in the first place of course, fall on the parish where the pauper happens to be; if he has resided there, under the first Act, for five years, but now reduced to three, the relief is charged to what is called the common fund, or the pauper has to be removed to his last place of legal settlement. It is much the same with regard to mining property as it is with regard to any other property.

3117. Although the lord would not derive any great advantage from such a provision as I have mentioned, you still think that he has the power to make it ?—Yes ; he has the power of making any conditions he pleases when he grants his set.

3118. And you think it desirable, for the sake of the miners, to make some provision of that sort ?—I say that it is a responsibility of the direct employer, who is the adventurer or shareholder, and I would put it in a familiar way. If you had a valuable horse and got a good day's work from him, either as a hunter or a draught horse, I think you would take care to put that horse in a good stable, and see that horse well groomed. For the working miner, after a hard day's work, when he comes to the surface, no provision of that kind is made, with rare exceptions. I admit that in some parts of the county there are exceptions.

3119. Are good changing-houses the exception ?—Changing-houses are the exception ; there are some "dries," as they are called, which have been very recently put up in this neighbourhood ; they are now being lengthened, and I hope that they will also be further improved. The dry itself does not, I should say, afford a man a decent place for the change of his clothes.

3120. Have any changes houses been put up on the representation of Lords ?—I have known where an improvement has taken place ; but still it is an imperfect one. The dry is there, and the miner may change in the dry or go to his barracks.

3121. A miner who changes in the dry suffers considerably from the dust, does he not ?—I do not say that he suffers ; but it is not a pleasant place to change in ; nor is it decent that men should be stripping naked one before the other.

3122. Is this dry sometimes in the boiler house ?—They are allowed to use the boiler house, as a dry, at times, where they have no dry put up. In some mines they have a dry, as it is called, which is a fireplace with a continuous flue, put up for the avowed purpose of drying the men's clothes.

3123. What do you think that such a building ought to be ?—I rather think that I have already put the public in possession of my views upon that point. I shall be happy to repeat them if it is desired. Perhaps it is right to explain myself. I will commence by tracing the condition of the miner when coming to grass. I find, that among tut-work, men who have done their work below, they are prohibited from coming to grass until the bell has been rung, which would summon them up ; that if a man should come to grass before the bell is rung he would be spaled the sum which the agent inflicts as a fine, and, as I am informed, that is usually 2*s.* 6*d.* I think that it would be far better for the miner, and more conducive to his health, if he were allowed to come direct from his work to grass without loitering either in the levels or in the ladder-ways, and to go to the dry, obtain his clothes, be required to dust them and beat them against the wall outside, and go to his changing house, where he might easily be provided with a tub of water or a bath, if the means of the adventurers would admit of it, which water might be heated by a boiler in connection with the dry, or a pipe from the waste water of the engine-house, put on his dry clothes, and go to a sitting room, and there wait to answer his name when required to do so by the agent.

3124. The men do stand on the ladder-way ?—Yes.

3125. Do they get cold in consequence ?—When I have inquired of the working miners themselves, as tut-work men, I have almost invariably found that their desire to get to grass before the relieving corps comes down, and has command of the ways, is in order that they may take their time in passing through the levels and up the winzes, or whatever they call the footways in the mine, and they remain in the

ladder-ways near the surface waiting for the bell to ring. Above the adit level there is a continuous current of air, and the fact of a man, heated with the exercise of climbing and travelling in the ladder-ways, then sitting there to rest, must of course, be injurious to his health.

3126. Are any means taken to give notice to the men below when the time is up ?—No.

3127. Then they judge only by their candles, I suppose ?—I do not know whether they judge pretty nearly from their candles or from other means which they have of knowing ; but they are not particular about that. If a man has driven his stent he wants to get to grass as soon as he can. The word "stent" meaning the extent of ground which happens to be set to him. I should wish to express my very strong opinion as to ladder climbing. I do not believe ladder climbing, in itself, to be productive of disease. I think that, to a diseased man who is put to climb a ladder, it must, of course, be most injurious ; but I think that it is not in itself productive of disease. The effect of ladder climbing, in the case of healthy men, is merely to produce muscular pain and fatigue. I will endeavour to illustrate that by the circumstance of sailors climbing the mast-head. If you put a man who is fatigued on coming on board, or who happens to be tipsy or ill, to the mast-head, it will be a very severe punishment; but it is no punishment to them—a healthy sailor, in an ordinary state. In mines, I think, I am right in saying that agents have frequently to travel and climb a larger number of ladders than the working miner himself. I hear of no disease among the agents incident to that ladder climbing, and I think that, as a whole, if there has not been disease before they have become agents by working in foul air as miners, a more healthy body of men you cannot find anywhere than they are. I arrive at the conclusion from that fact, that ladder climbing is not productive of disease. I admit that it aggravates disease very seriously in a diseased man.

3128. Ladder climbing not being, in your opinion, injurious in itself, if a man had been working in bad air, and then had to climb, would it not be injurious ?—I believe that it would be most injurious.

3129. Whether he was diseased or not ?—I say that a man directly he inhales bad air is diseased. Of course, I speak with great deference to a medical man, but the object and functions of the lungs are well understood, and the sensations which a miner describes to me, I believe, from professionally having read medical jurisprudence, are indicative of impeded respiration. A miner will speak to you of, what he calls in Cornwall, a creaming or pain about a part of the chest ; doubtless the bronchial tubes there must be full of what is termed azote or nitrogen gas.

3130. Supposing that a miner was working in good air, but doing a very hard day's work, then would the ladder be in no way injurious to him in your opinion ?—No ; I believe that it would be merely additional fatigue to him. I speak of a miner, supposing he has been working in good air and in a well-ventilated mine. I think that the fatigue which he experiences is muscular fatigue of the arms and chest, similar to that which I might experience after a long day's march ; and if I met your lordship, and you were kind enough to offer me a seat in your carriage, I should be very pleased to have a ride home. I can say no more of that as far as the ladder climbing goes ; but I think that it might be made perfectly clear to the Commissioners, in going through this county, that it really is the interest of the proprietors of mines to expend money in sinking shafts and winzes in an economical point of view.

3131. Do you consider that the mines generally are ill ventilated ?—In speaking of mines being ill ventilated, I believe that a mine which has been much worked, and in which there are a number of shafts and winzes, as a whole cannot be said to be ill ventilated ; but in those mines where men have to travel the ends of a level, or to rise in the back of the lodes, there is no ventilation at all.

3132. In the mines with a number of shafts, are there not ends with poor air also ?—Wherever a man passes beyond the point of ventilation, of course he is at once breathing an impure atmosphere.

3133. Will you explain what you mean by an adventurer ; do you mean a shareholder ?—I do ; it is the old-fashioned term in the county ; a mine was called an adventure in olden times, and the miner who worked in it was called an adventurer.

3134. In some of these mines I suppose there are a very large number of adventurers ?—I am sorry to say that the practice obtains now of dividing the shares into a greater number ; some people hold the opinion that it is an advantage for persons having small means to be able to invest their money in what they call good dividend-paying mines; but I believe myself that it is increasing the evils which are found to exist in this county by so dividing the responsibilities, and by such a constant change of shares from hand to hand, that there is almost an inability in certain mines to fix who the adventurers are.

3135. And, therefore, where the interest of the miners is concerned, there is nobody but the agent who is in any way responsible ?—The shareholder for the time being, of course, is obtaining as much money as he can, and if you asked him to spend 4,000*l.* or 5,000*l.* in sinking a shaft, he would rather avoid doing so than make that outlay.

3136. Then a very great evil is the number of shareholders, and the want of responsibility in those who work the mines ?—Yes ; I think that it would be prudent on the part of all shareholders to have such a reserve fund as would enable them to carry out the means of effecting the improvements of which I have spoken ; and I think that it would be eventually found that they would be handsomely paid by the money so reserved for expenditure.

3137. But if the shares are constantly changing hands that could not be carried out ?—No. In almost every Act of Parliament which has been passed for public companies or railway companies there is what is called a fund for contingencies or a reserve fund.

3138. Does the lord in giving off the set ever make a condition that the shares shall not exceed a certain number or amount ?—Very rarely.

3139. It is done ?—I have done it recently ; but it is not done as a rule in the county. I am not aware of another case.

3140. Do you think that it would be a good rule ?—I think that the less the lord interferes with the action of companies the better.

3141. But it would be so far a good rule for the miners ?—I think so. I think that they would work the mines with greater economy.

3142. Then you think that it would be for the interest of the adventurers that proper ventilation should be provided ?—I do certainly, in order that a greater amount of work may be done at less cost. If a man has a piece of ground set to him at a deep level, with no ventilation in the end, it is impossible that that man can do so much work as he could in a level well ventilated; and I think that in many of those cases a very simple remedy might be applied,—at all events, in some instances, if not generally,—namely, what is called having an air soller, by which the air might be forced on from the mouth of a winze to the end of the level. I am speaking of the upper levels ; in the bottom level there is a difficulty, because you have no winze below that ; and nothing but keeping the shafts going with the levels, I believe, will ever remedy the defect.

3143. We have been informed that the air sollers become expensive, as they wear out from the passage of the barrows on the wood ?—When a man's wheelbarrow is getting worn out, the sooner he gets a new one the better ; that is all I can say about it.

3144. Proper ventilation becomes a question of expense, in your opinion ?—Yes ; I do not think that that is a serious answer to it. I cannot positively speak as to the best description of wood adapted to

lying under ground, whether it is exposed to damp, miners themselves know.

3145. With regard to a former question as to the health of the miners, is there any other point upon which you wish to give your opinion to the Commissioners?—No; I believe that the whole matter may be summed up in a very few words—better ventilation, and better provision for the miner when coming to grass and changing his clothes.

3146. (*Mr. Austin Bruce.*) Would you add the substitution of some other conveyance than that of ladders or not?—You allude, I presume, to what is called the man-engine?

3147. No, I do not.—I think that that would not be required, if the mere labour of climbing is taken as a part of the man's work. I do not attribute so much importance to it myself as others do. To a diseased man I think it is a most fearful punishment; to a healthy man, I do not consider it so.

3148. (*Chairman.*) A man works eight hours underground, does he not?—That is including going down and coming up.

3149. If it takes him from an hour to an hour and a half to come up from the deepest mines, that is so much loss to the adventurer?—Yes; and therefore it is the interest of the adventurer to give him more rapid means of coming to the surface. To put it in a plain way, if you have a mason to build a garden wall, to walk to the spot, and 20 miles to walk to go and 20 miles to come back again, he will not do so much work as if he is close by it.

3150. (*Mr. Kendall.*) You talked of certain clauses to be inserted in the lease which should provide fordries and other arrangements for the benefit of the miner. Do you think that if these clauses were to be inserted, if a lord was known to insist upon those clauses, it would be a barrier to an application for sets from him?—I believe that it would be a very great drawback, I will not say a barrier. I think that the lord ought not to be required to do it. I have endeavoured to point out that I do not think that it is any pecuniary advantage to him, but that it is a mere matter of feeling and moral responsibility that somebody ought to do it, and the lord does it, if the adventurer does not. I am entirely of opinion that the sets granted by lords ought to be as free and wide as possible.

3151. Supposing that a lord felt that there was a great responsibility on him, and that he had no right to grant sets to parties who he was not sure would provide for the accommodation of the miners, do you think that he would be less likely to have applications for sets than another lord who was less scrupulous?—I do not, eventually. I am speaking now of the lord doing that act which another person ought to do, and where I found that the mining companies had neglected to do it, and I had no means otherwise of seeing it done, I would, upon the renewal of the set, if I had the opportunity, ask the lord to insist on certain things being done. That is all that I can say about it. I think myself that sets or licences when first granted should be as free and wide as possible, without being embarrassed with any restrictions.

3152. If the miners were to be allowed to come direct to the dry, instead of waiting in the shaft for some time before the right time for coming to the surface, how would you prevent the abuse of that privilege?—By requiring the men to go into a sitting-room, which should be well warmed, and where they might have their own refreshment provided by themselves, and they would be required to wait there until they had answered some roll-call or answered their names to the agent.

3153. Would there be no abuse in that; might not a man, in that case, come up an hour before his time?—He is obliged to do a certain amount of work in the course of the month, or he does not get his wages, and I believe that the tut-work man has very little opportunity of getting more than such wages as the agent chooses to fix. If a miner has driven beyond his stent, and has a soft piece of ground in his end, he will derive little or no advantage from that in the next month's taking, except in this, that he, perhaps, will execute the work in less time, and will have more time at his own command.

3154. According to your idea, a miner should be enabled to leave his tut-work pretty nearly when he likes?—Yes; it is set to him, at per fathom, which he is to drive in the month.

3155. And he may leave when he likes?—Yes. I know not why he should not do so, if a man drives his quantity of ground. I know that the suspicion on the part of the agent is, that a man should not be allowed to run away when he pleases, and therefore he keeps him down this trap hatch.

3156. With regard to the ladder-climbing, you have no objection to the ladder climbing?—None at all. When I say "none at all," I speak with a qualification. Supposing that I am in a healthy condition, and have time to do it, I do not object to ladder climbing; I would as soon climb a ladder as walk.

3157. I understand your reason to be this: that you look at the mine agents, and a healthier class of men you cannot see, and that they have much more climbing than the men?—Yes, I am speaking of days when the agents go down.

3158. As I understand the matter, the miner has to go down to his place of work direct and returns direct, and there is an end of his climbing; but the agent goes much further?—Miles further in a day.

3159. And you say that the agent is a healthy man, and receives no harm?—Yes; it is no punishment to him.

3160. Is there not a very great difference between even a healthy man coming out of an end, where he has been for eight hours, and then having to ascend, and an agent who is shifting his ground almost every five minutes, and who is not coming out into the open draughts and getting near a shaft and then descending in the main shaft and getting cool at all; is not his descending and returning a different case from that of a miner who descends and goes into an end, which may not be very close but still is an end, and where the air cannot be so pure as that which the captain is breathing almost every moment, except a second or two now and then, during the whole time he is below?—I believe myself that the captain breathes very little impure air, he is constantly passing through the winzes up and down, and has a current or air which does him no harm.

3161. Is not his case a different case from that of a man who is in one fixed spot?—Undoubtedly so; the agent comes up in better condition, because he is in constant motion, and his animal heat is kept up, but the miner sits down when he has been perspiring very freely and sustains a check, all of which, in my opinion, does him great injury.

3162. (*Chairman.*) And the miners are in the constant habit of standing on the ladders?—So I am informed.

3163. Do you think that the tut-work men would abuse the privilege which you have suggested that the miners should have?—I think not seriously; if they did not work the quantity of ground they could not get the wages. It is rather an amusing thing if you go underground to see the setting of a stent, the agent himself does not wish to be what he calls baffled by the miner, and if the miner can drive a fathom of ground in a shorter time than the agent sets him, the agent may think that perhaps he may not stand so well in the opinion of his employers as he otherwise would do. The agent's object is, as far as he can, to show that he is clever in his way of setting, and that he has allotted the man a fair amount of work for the two months, supposing he works eight hours; but a working miner can very frequently execute the work in less time, and come to grass, if allowed to do it.

3164–5. (*Mr. Austin Bruce.*) I presume that the agent agrees with the workman as to the price to be

LISKEARD.
Mr. C. Childs.
19 April 1862.

given for the work, he being himself the judge of the quantity of work?—Just so. There are two ways of doing it; first, there is what is called the setting day, when so many fathoms of ground are set at public auction by the agent; and perhaps in some mines you have seen a bow widow where the agent sits and put up so many fathoms of ground to be driven; he puts a certain price on it, and there is a kind of Dutch auction, and the lowest bidder before a stone is thrown up has the ground set to him—John Crossman and pair, or some such taking. If, before the end of the month, or two months, for which that ground is set out, he has driven the full extent of his ground, the agent, in coming down below, will then make an independent bargain with him for what he drives beyond his stent.

3166. Is it an understood part of the bargain that the miner should remain a certain number of hours at work every day, so as to complete the work within the shortest possible time?—No, it is not, as far as I am informed.

3167. Then why should the agent object to the miner leaving his work at any time he pleases?—Because the agent is supposed to set the quantity of ground which a man, working so many hours a day, should fairly, with his pair, drive.

3168. Is that the only reason?—That is the only reason that I am aware of.

3169. Do I understand you rightly, that eight hours being the time which a man is expected to work that includes the time he takes in ascending and descending the ladder?—Quite so. The change of corps is every eight hours.

3170. You have expressed an opinion, that the mere ascent of a ladder at the end of a day's work, provided a man is not diseased, occasions no injury to him?—No; not beyond the muscular fatigue.

3171. What is the depth of the deeper mines in which ladders are still used?—I am not prepared to give an answer to that question. I do not know what the extreme depth in the county is. I think that Tresaveane may be said to be one of the deepest mines in this county.

3172. Can you tell us the general depth of the deeper mines?—I cannot. I should say 200 or 300 fathoms. In the course of mining an adit level is driven, and it is only from the adit level that the number of fathoms is reckoned.

3173. What is the height of the highest mountain in Cornwall?—That I am not prepared to give you.

3174. Have you any 300 fathoms high?—I cannot tell you. I think that Liskeard is somewhere about 300 feet above the level of the sea.

3175. Do you suppose that an ordinary man, through the whole of his working years, could ascend from 1,200 to 1,800 feet, in what necessarily must be the close air of a shaft, without bringing on injury to himself?—Certainly not.

3176. Is that not the case with miners who are also exhausted by the use of the borer and by other labourer's work underground?—Yes; but where you have winzes and shafts you will find very little foul air; you will find a current, which is a supply of pure air, consisting of oxygen. The miner himself will frequently work in a dark place where a candle will not burn.

3177. Do you conceive that, with any arrangement of the ventilation, the working underground in a comparative darkness, and breathing air necessarily vitiated by candles and powder, as well as by gases, can be as healthy as work in the open air?—There is not the slightest doubt upon that point; it is decidedly not so healthy.

3178. Then work under those conditions must take more out of a man than work in the open air?—Decidedly.

3179. Even supposing that man's health not to be seriously affected, do you think that the addition of an ascent by a ladder of 1,200 or 1,800 feet could be effected without ultimately causing injury to his health?—I should say, that as far as producing disease goes, there would not be more injury than in any other pursuit, supposing the shafts to be well-ventilated.

3180. Does not excessive fatigue bring on either disease or a tendency to disease?—Excessive fatigue is beyond that which a man can fairly bear. If I walk a long distance and walk further than my strength will carry me, no doubt I shall suffer from it. When the word "excessive" is used in that way I should say that it would, of course, be productive of disease; that you are using up the material quicker than you should do. But I think that those questions are rather more adapted for a medical man than for one in my position. I am merely giving you the opnion of a common observer, without my opinion being, perhaps, of the slightest value upon these points.

3181. You have been much in personal communication with working miners?—Yes, constantly.

3182. Judging from your experience of miners, should you say that the majority of the miners at the age of 40, in this district, were affected by the direct results of their work underground?—Yes; I believe that the miner at 40, whose fate it has been to work in bad air, begin to decline and decay at 40, if he ever lives to attain that age.

3183. I do not ask you with reference to the miner who has worked in bad air, but to the whole body of miners generally?—Yes; those working underground, I think so.

3184. (*Mr. Fulke Egerton.*) Do you think that there has been a tendency in the last few years to improve the ventilation below and the arrangements above for the miners?—I do.

3185. Do you think that there is any marked improvement which can be traced during the last 10 years?—Yes. I believe that men may now at times, on application to the agents, be supplied with the means of making air sollers, or may go to the timbermen, as it is called, and have a pipe or tube of wood. At the surface the dries are of very great advantage to the men, and it would be an improvement if they had some little addition to them in the shape of a sitting-room and a changing-room, and the expense would be very inconsiderable.

3186. (*Mr. Holland.*) I think you say that, with the exception of the ends beyond the winzes, the air of the mines is good?—It is not so bad, when you compare the pure atmosphere on the surface with the impure atmosphere below; it cannot be called good as compared with the atmosphere at the surface.

3187. A very small proportion, I believe, of men work in that bad air?—All men working in a rise, which is a vertical level, and all men working in ends work in bad air.

3188. What proportion work in bad air?—I have no idea.

3189. If the miners, as a class, begin to fail at 40 or soon afterwards, and if that failure is produced by bad air, is not that a proof that the air is generally bad?—Yes. In many levels a man is driving an end, and there are tributers in the backs behind him, and they have to throw the ore down into the level, and of course they are choking up the level.

3190. And choking the men beyond them?—And choking the men beyond them. And I may say that I have myself gone a considerable distance (I cannot say miles) where I have had to scramble on my hands and knees, and there has merely been room for a man to pass through.

3191. If there are a good many ends in a mine where a candle will hardly burn, or will not burn, must not all the air in that mine be bad?—No.

3192. Why not?—Because when the slightest amount of pure air or oxygen passes on into that neighbourhood, the candle will begin to burn and the men will feel better.

3193. But it is still bad?—Yes, certainly; anything which is below the proper test of pure air, of course must be bad.

3194. What is the proper test of pure air?—I

should say the surface; for instance, if I take an ordinary candle and put on a receiver, I can almost put out that candle. I could almost destroy a miner in a few moments in that way, and revive him in a few minutes. If you give the slightest supply of pure air containing oxygen, you will find the candle burn again.

3195. Is not the air in which a candle begins to burn dimly not only bad, but very bad?—It is going from bad to worse; as the candle goes out so the air becomes worse.

3196. If you saw the candle in your drawing-room beginning to burn dimly should you feel comfortable?—I should think it time to open the window.

3197. (*Mr. Kendall.*) Your own experience has been more above ground than under ground?—Quite so.

3198. You have been very little underground?—Very little. My visits underground have been more a matter of curiosity then as a vocation.

3199. Have you been down any of our deep mines more than once?—I have not, and I do not intend to go a second time.

3200. Then your own experience underground is very small?—Very small indeed.

3201. And the little which you have seen you do not like; you would not like to go down again?—I have seen quite enough to inform my mind of what the underground workings are, and I could tell you from a drawing precisely what they are, and every working man in the county would corroborate it.

The witness withdrew.

The Rev. JOHN RICHARD PRETYMAN BERKELEY examined.

3202. (*Chairman.*) I believe that you are the Vicar of St. Cleer?—I am.

3203. How long have you been so?—18 years.

3204. When you first came I suppose it was principally an agricultural population?—The majority were agricultural at that time, but a very large proportion were miners. Perhaps three fifths were agricultural, not more than that I should think.

3205. What should you say is the proportion now between those engaged in agriculture and those occupied in mining?—I think it is rather more than reversed. The agricultural population, I thimk, has not increased, and the other has very much increased. I should think that now out of 4,000 there must be 2,500 engaged in mining occupations.

3206. Has it come under your observation that the deaths in the parish in proportion to the increase of the population have been greater during the last few years?—I have not exactly looked into that point. The point which I looked into was comparing the average age at death of the males who had come to an age old enough to go to work. I have taken, for instance, the age of 14, as the age when a boy might be said to be considered capable of getting his livelihood, and I have taken down the ages of all the males at the time of death over 14 whom I have buried. Taking what you might call the working age I find that the difference between the agricultural population and the mining population is very great indeed.

3207. Can you furnish the Commissioners with the results?—Here is the paper which I took out. You will find the ages of those who have worked as agriculturists very high indeed. St. Cleer parish is a remarkably healthy parish.

3208. (*Mr. Austin Bruce.*) Are these agricultural names taken in the order in which the owners of them died?—I have taken them as I found them in the book consecutively, merely entering those who were engaged in mining in one column, and all others not necessarily agriculturists, but agriculturists and others upon the other side.

3209. One column gives the deaths of the male population at a working age exclusive of the mining population?—Yes.

3210. And the other gives the deaths of the male mining population at a working age?—Yes.

3211. (*Mr. Kendall.*) All in the same period?—Yes. I have taken them during the last 18 years; since I came to the parish.

3212. (*Mr. Austin Bruce.*) Your general results are that 82 men of the mixed population, exclusive of miners, lived between them 5,433 years, or an average of 66 years, while 82 men of the mining population lived between them 3,134 years, or an average of 38 years?—Yes.

3213. (*Chairman.*) Do those two tables comprise the whole number of men who are registered as having died in the parish?—Nearly. Occasionally perhaps half-a-dozen have been carried out and buried elsewhere.

3214. But those are all who have been buried in the parish?—Yes. That is an exact copy from the parish register.

3215. Do you consider that the houses of the miners in St. Cleer are in a healthy condition?—No. I think that when a miner takes ill he has less chance of recovery than an agricultural labourer, from the fact that, generally speaking, the miners live in closer rooms.

3216. Is there any attention paid to the draining or the cleanliness in front of their doors?—That is a point in which I think that they are rather deficient. In the year 1849, when there was cholera in England, I succeeded in getting a system of drainage through the village of St. Cleer, with a grating at each door; but we find it very difficult to induce them to keep those gratings clear. They think that it rather interferes with their personal liberty, and that they have a right to throw things where they please. They do not like to be interfered with.

3217. (*Mr. Austin Bruce.*) You have visited of course many sick miners?—Yes.

3218. Do the figures which you have given coincide with the impression which you have derived from your experience of your parishioners from visiting their sick beds?—Yes, I should think so. I would mention one fact which I have noticed. I may almost say that I have never known a case of a miner after he has past 21 or 22 and has come to man's estate, have anything like a severe fit of illness and becoming a thoroughly sound man again.

3219. Do many of the miners of St. Cleer go elsewhere to die?—No, very few indeed; our parish rates will tell you.

3220. I ask this question as I know that it not unfrequently happens that the natives of rural parishes, when no longer able to work, return to their native parishes to spend their last years?—It is a very rare thing indeed with us. I have known very few instances of the sort. I will not say that I have not known any, but they have been very rare. In fact, when they are exhausted, they generally look for assistance from the parish, and then they are unwilling to move. There is always a difficulty in that respect.

3221. Have you known any of the natives of St. Cleer who have gone to the large towns to work, return to St. Cleer to die?—I do not think that I have ever known one.

3222. I suppose that the surplus population of St. Cleer who cannot be employed in agriculture readily find employment in mining operations?—Yes. The parents of a great many of those who are now engaged in mining operations in St. Cleer were agricultural labourers in the parish of St. Cleer.

3223. Do you consider that the children derive any hereditary infirmity from the complaints of their parents?—I am frequently called upon to baptise infants privately oftener of miners than of any others, and I generally find that they are suffering from chest

LISKEARD.

Rev. J. R. P. Berkeley.

19 April 1862.

disease. What is the cause I will not undertake to say, but still I think it is more than likely to arise from the circumstance which you mention.

3224. Taking miners of between 20 and 30 years of age, are many of them suffering from illness?—I think that after they come to man's estate they are more liable to those attacks than before. I think that if you say from 20 to 30 I should find a difficulty in answering the question. If you ask me from 18 to 25, and then from 25 upwards, I could give you a much more direct answer. From 18 to 25 I think they are generally fine specimens of men, superior in their appearance, and you would judge them to be physically stronger than men of the same age engaged in agricultural operations; but I think that after that they go down the hill much more rapidly, especially if they in any way get any cold.

3225. Do you find them suffering much from colds contracted from their work?—Yes; very frequently. If I see a miner looking ill, and I say, "What is the matter with you?" he says, "The pipes, sir." That is always the answer.

3226. What do you mean by "the pipes"?—I believe that they mean the bronchial tubes. They say the pipes are stuffed. It is there that they suffer.

3227. Have you been underground yourself?—Never.

3228. (*Mr. Kendall.*) Have you ever classified the cases at all as to the mines from which the miners have come?—No.

3229. Have you observed whether there has been more ill-health on the part of men working in one set of mines than in another?—South Caradon, as far as I can see, is the healthiest mine in our neighbourhood. Craddock Moor has a bad name even with the men themselves, and of East Caradon I have heard many complaints of late; that is, on the score of ventilation. Of course upon anything respecting the ventilation of the mines I must merely speak from hearsay. I know nothing of it myself.

3230. When the miners have been ill, and have come under your notice, and when you have been inquiring, you have found that more have come from one district than from another, and you classify them in this way, South Caradon the most healthy, East Caradon next, and Craddock Moor the worst?—I have heard very little of East Caradon until lately, because very many of the men working in East Caradon, I think, are from Linkinhorne and Liskeard. It is comparatively a new mine in its present condition. A miner was speaking to me on Thursday, and he was saying that East Caradon was very bad.

3231. When they have been ill, have they given you their reasons for becoming so ill; have they attributed it to bad air or climbing?—A great many have complained of the air of Craddock Moor.

3232. Do they attribute the causes of their illness to bad air?—They attribute their illness to bad air more than anything else.

3233. Not to climbing?—No; but they have spoken of that as being very fatiguing. The men, I think, often complain of their liability to catch cold after they come up to the surface.

3234. From the want of dries?—Yes; having a great distance to go to the place where they change. A great portion of it is, perhaps, their own fault; they stand and talk about the mouth of the shaft before they go to the dry.

3235. Taking them as a whole, are they careful of their own health, or not?—I do not think that they are as careful as they might be. A man will feel himself indisposed, and instead of seeking medical aid at once, as I have often entreated them to do, he will go on for a week or two longer before he calls in a doctor; they seem to have a great horror of the doctor.

3236. (*Mr. Austin Bruce.*) Are the doctors, as a class, attentive to them?—I do not like to express an opinion upon that point. I have seen some cases of neglect. I think that the great difficulty is that there are not doctors enough; it is too large a district.

3237. Do you think that, as a rule, the doctors take their cases in hand early enough?—I think they take them as early as they are applied to. I have frequently had complaints from the doctors themselves on that point. A doctor has said to me, "What am I to "do with that man; he ought to have been with me "a fortnight ago; it has now fastened on him."

3238. Do you believe, without having specially enquired into the matter, but from your knowledge of the circumstances of surrounding parishes, that the results in surrounding parishes would correspond with the figures which you have given to the Commission?—I cannot undertake to answer that question. I do not know. I have had no conversation with others on the subject.

3239. Do you know anything in the circumstances of surrounding parishes which would tend to make the results different from those in your parish?—I do not.

3240. (*Mr. Fulke Egerton.*) Have you ever heard any complaints from the miners with regard to the distribution of the club money at the mines?—No, I do not think that I have. I have heard the men say that they think that they do not get enough for the money which they contribute to the club; and on one or two occasions where mines have gone down, I have known men to complain, because it is lost in some cases; but that is very unusual. I do not think that the men have made anything that you could call a complaint sufficient to form an opinion upon it.

3241. (*Chairman.*) Should you say that the miners, as a class, save money?—No, not as a class. The men who save most money, as far as my experience goes, are those who were brought up as agricultural labourers, and have gone, perhaps, when they become young men, to work at a mine. Those very often save money. They have been brought up in another school.

3242. Do you think that the miners have food and nourishment sufficient for the work which they undergo?—Their food is of that character that I do not think it can contribute the nourishment which they require, looking at the varied nature of their occupation.

3243. What is the general food of the miners?—Those heavy pasties which they carry with them, and which I think are quite complete engines for the destruction of health, especially in the case of men engaged in the miner's occupation. An agricultural labourer working in the open air can eat almost anything; a miner working in foul air, and his occupation taking more out of the system, is not able to digest the same kind of food. I find very many of them, for instance, who cannot eat fat; the stomach rejects it.

3244. What food does a miner, returning home after work, get when he comes home?—Generally speaking, first there is broth made of a lump of fat, perhaps, put in water, and some vegetables; and then the amount of meat which they have (fresh meat especially) is very small.

3245. What amount of meat in the week should you say that a tut-work miner can afford?—I cannot exactly tell, but you rarely see the wife buy more than seven pounds of meat a-week at the market. That is considered a large supply for a week, and there are, perhaps, a man, his wife, and three or four children.

3246. At a work where a good deal is taken out of them, it is your opinion that there is not sufficient nourishment?—No, I think not.

3247. (*Mr. Kendall.*) Which do you think buys most meat, the miner's wife, or the agriculturist's wife?—The miner's wife buys more meat in the market, but I question whether the agriculturist's wife has not as much at home; because the agricultural labourers are better supplied with bacon and things of that sort than the miners are, and are better able to use it.

3248. (*Chairman.*) The agricultural labourer, you think, has more bacon, which he makes himself?—Yes. It is a rule in our neighbourhood that every agricultural labourer is entitled to a run, as it is called, for his pig; and then there are generally a good many turnips, and things of that sort, which they are allowed to have from the house, and a good deal finds its way to the pig. Then they are allowed to buy their barley at a certain price; and perhaps the pig is killed, if they are in debt for the barley, to pay for it.

3249. You think that the agricultural labourer is better fed than the miner?—Yes; but at the same time I do not think that he has, perhaps, as much fresh meat each week.

3250. Although his labour is not so severe?—Not so exhausting to the system.

The witness withdrew.

Mr. Andrew Kingston examined.

Mr. A. Kingston.

3251. (*Chairman.*) I believe you are mayor of Liskeard?—Yes.

3252. You are also a surgeon?—Yes, to several mines.

3253. How long have you practised as a surgeon?—Twenty years.

3254. In Liskeard?—Yes.

3255. And I suppose that among your patients you have had several of the mining population?—Yes.

3256. Have you many cases at this moment?—Not many; our district is remarkably healthy at the present time.

3257. With regard to miners, are the number of miners' cases more in the winter or in the summer?—They are more in the winter.

3258. Can you mention any large mines from which you have had more cases than from others?—West Caradon Mine is my large mine.

3259. Are there small mines which you attend?—Yes; I am the medical man to about ten or a dozen mines; West Caradon, Craddock Moor, Herodsfoot, Ludcott, and others.

3260. (*Mr. Austin Bruce.*) Are you the only surgeon attached to those mines?—Yes. I am not joint surgeon with any medical man, excepting in Phœnix Mine, which is a large one, and there we have a geographical division. I take those men who live south of a certain line, and he takes the north.

3261. You keep assistants, I suppose, to help you?—Yes. We have a very cordial understanding in the town; we all help one another. We are five or six medical men, and we have a very good understanding, so that we have no difficulty if we are out of the way.

3262. (*Chairman.*) Have you many cases of accidents in mines brought under your notice?—We have in the course of the year. We have had rather a large number of gunpowder accidents lately in my district. I have had three within the last three months.

3263. What sort of accident is that?—The holes going off prematurely.

3264. What has been the effect?—Two of the men have lost both eyes, and one has lost one eye; and one accident, which occurred only this last week, was a very trivial accident: the man had a few marks over his face, and his hand was burnt. They almost always burn the hand.

3265. In those cases have you asked the men how the accident occurred?—Yes, I generally do; and it is generally in what they call the picking out the holes. The last accident was in tamping; it occurred as soon as he began to tamp. I said, "Had you nothing soft?" He said, "There was nothing soft there." So that he tamped with a hard material, and the powder exploded immediately; but the powder only just being in, he was not injured much, the burden of the hole was not thrown.

3266. Were these experienced miners?—Yes, all of them.

3267. Are there any regulations?—I believe that nearly all the accidents have been contrary to the regulations, and might have been prevented.

3268. Arising from the men's carelessness?—From their own carelessness.

3269. Are there any direct instructions given to the miners with reference to picking the holes?—Yes. They should all be picked out; but sometimes they bore them out. They put in an iron rod, and beat away; they should be gently picked out. It is done to save time.

3270. Are there any other sort of accidents which have come under your notice?—Fractures; a few accidents from machinery. I have had two accidents where youths have been caught between the rollers that grind up the ore, and they have each lost a leg.

3271. Is there any protection?—There cannot be any protection there. They have slipped back, having forgotten it; you cannot cover up the opening; but while the thing was at work they appear to have

LISKEARD.

Mr. A. Kingston.

19 April 1862.

forgotten it; they suddenly stepped back, and put their leg between.

3272. Could there be no protection?—No, nothing could prevent that.

3273. About what age were they?—Fifteen or sixteen.

3274. Was this exposed to the weather?—No, under cover.

3275. Will you state to the Commissioners what your observations are with regard to the diseases of miners?—The bulk of them are affections of the chest.

3276. How, in your opinion, are those diseases caused?—I think by three things: poor air, occasionally working out of light (they are a long while out of light), and climbing.

3277. We will take first the poor air; that is in driving an end, and there is a want of ventilation?—Yes.

3278. How does that affect them?—They lose colour and they waste; and they complain of general lassitude, and sometimes of giddiness in the head, and shortness of breathing with it.

3279. Do they come to you at once?—No; a man does not come until he finds that he is a good bit incapacitated. He would not apply to his medical man for that.

3280. Not until he finds himself unable to work?—Perhaps before that, but still not until he is affected a good bit.

3281. When he finds himself not so strong and able for his work?—Yes.

3282. Added to that, you state the working out of light?—Yes.

3283. Do you suppose that the air is bad there to a certain extent?—In most mines there must be ends where there is poor air, because they are driven a long way from shafts, and they have not winzes through. They get winzes through as fast as they can, I believe; but sometimes they are many weeks and sometimes months driving in poor air. Then they suffer from the effect of powder smoke and candle smoke.

3284. With regard to the poor air, what do you mean by poor air?—I mean air where there is a difficulty in a candle burning; that is the criterion here. There is, no doubt, a deficiency of oxygen in it.

3285. Is the rest of the mine affected at all by the powder smoke and the candle smoke and this air from the end?—It will only just affect that end of that level. It would not affect the bulk of the mine.

3286. When it escapes up an up-cast shaft the other part of the mine is not affected by it?—It is then, I believe, got rid of.

3287. But any one working in that shaft would suffer?—They are below it. They are working in the bottom of the shaft; they are not working on the sides of the shaft.

3288. You have alluded to climbing; what is the effect upon the miners of climbing?—The act of climbing first of all produces a very violent action of the heart. Then they have to breathe more hurriedly, and I believe that they get what is termed emphysema of the lungs, which I can explain. (*The witness made a sketch.*) Supposing that to be a bronchial tube, and these to be air cells influenced by the violent breathing of bad air for a series of years, these air cells, instead of being very small indeed, become large, so that the lungs are always full of air, but yet they do not get a proper quantity of fresh air. We have a number of men in the mines from one time to another who come to us, and they are failing, and they look as if they were consumptive, and we examine them, and cannot find any trace of consumption at all. We strike them on the chest, and their chest is much more resonant than it should be; and I believe that it is owing to this emphysematous condition. We have had several such men from time to time, and there are some about now, I think. They cannot make any exertion. They are well up in flesh, and some of them look the picture of health, but they cannot work at all, and they are home for months and months. Then these cases often terminate in consumption.

3289. Would they terminate in consumption if the men did not go back to the mine?—I have found a great difficulty. I believe that many of them would not. I think that if they did not return to the mine they would live on for many years. I recommend some men not to go underground, and they immediately turn round and say, "What shall we do, Sir?" I say, "Do anything; work with a farmer." They say, "The wages are not enough." Then they apply to the mines, and there is not surface work on the mines for them to do. They have a great dislike to agricultural work after they have worked at a mine.

3290. And therefore they return to the mine?—Yes; and after a little while the difficulty is added to until they get thoroughly incapacitated.

3291. And it generally ends in consumption?—Yes.

3292. (*Mr. Holland.*) What they call consumption?—Yes.

3293. (*Chairman.*) What would you term consumption?—I think that many of the cases are proper phthisis.

3294. Is the heart affected?—With many of them.

3295. In your opinion is that brought on by climbing the ladders in combination with working in bad air, or would it be brought on by climbing the ladders if they did not work in a bad end?—I think that it is brought on more quickly by climbing with occasional poor air, because they cannot help powder smoke and candle smoke. They must have that if the mine is a hard mine using powder, whatever good air else they may have.

3296. So that though the air is not poor the breathing of the candle smoke and of the powder smoke, and the climbing, tend to produce the effect which you have described?—Yes.

3297. Are the liver and stomach affected in the first instance?—Very little. We are not troubled with affections of the stomach or liver with the miners. They are a very temperate class of men, so that we do not get any affections of the liver from drink. There is very seldom anything of that sort.

3298. The men on coming up from the mines after working in poor air, we have been told, complain of loss of appetite, and of not being able to eat. Does that arise from the state of the stomach, or from the inhalation of poor air?—I do not hear any complaint of that kind, but I have no doubt that after working in poor air they cannot eat so well.

3299. Has it come under your observation that they have caught cold, or that what they call their pipes have been affected from catching cold?—They often come as other persons do, and say, "Well, I have caught cold, Sir." We hear that from them in common with other persons.

3300. Do they say that their pipes are affected?—They do. They say that very frequently. They say that they cannot breathe; that they have a difficulty on their pipes.

3301. (*Mr. Holland.*) Do they use that expression generally for their lungs?—For the whole concern.

3302. What we should call the bellows?—Yes.

3303. (*Chairman.*) And they believe that to be from catching cold?—They often say so. They say, "We have caught cold."

3304. Is it your opinion that that arises from their work?—I believe that they have caught cold, and then the lungs being a little impaired in their functions it puts them to more trouble than an ordinary agricultural labourer would experience.

3305. Are there any special reasons why a miner is subject to catch cold more than other persons?—I think that the character of his employment would be very likely to induce cold more frequently than in other persons, because the miners are working in a warm temperature, and they come up into a cold one.

3306. Where do they come up to?—They come up

from a shaft, and there is generally a dry on the mine.

3307. Have you ever visited any of the changing houses ?—Yes.

3308. Are they warm and comfortable ?— Those that I have been in have been warm.

3309. Do the men experience any inconvenience or injury to health from the amount of dust in those changing houses ?—I think that where there is plenty of dust it is a disadvantage to them.

3310. If they change where the clothes are dried are they liable to be subjected to much dust ?—Yes. Dust comes off their clothes. I do not think that they would feel it much if they were all right otherwise.

3311. But being somewhat affected, as you say, that would tend to increase the inconvenience ?—Yes; it would tend to irritate their chest.

3312. In your opinion, are miners more subject to disease than the agricultural population?—Yes ; much more so.

3313. To the extent of shortening life ?—Yes.

3314. (*Mr. Holland.*) They are older men at the same age ?—Yes ; they look very much older ; a man of 30 looks 40.

3315. (*Mr. Kendall.*) How long have you been practising in a mining neighbourhood ?—All my lifetime. I never practised in any other neighbourhood.

3316. As I understand from you, a miner, generally speaking, is averse to applying for medical aid till he becomes seriously affected ?—No ; I would not say that ; but I do not think that he would apply till he found a good bit of inconvenience, if he was able to work.

3317. If the complaint, on account of which he applies, were taken in an early stage, you think that it would be well met ?—Yes.

3318. It has been stated, that if a miner is once taken ill, he scarcely ever gets a strong man again ; is that your view ?—It is not my view at all.

3319. When you go into the miners' cottages, you are of course in the habit of being there at all hours, and seeing them at their meals ?—Yes.

3320. You likewise see agricultural labourers at their meals ?—Yes.

3321. Taking the food of a miner and the food of an agriculturist, which is the best of the two, generally speaking ?—The miner's is a great deal the best.

3322. Does the miner use more meat than the agriculturist ?—A great deal more.

3323. A great deal more beef ?—A great deal more beef.

3324. A great deal more mutton ?—Animal food.

3325. The agriculturist sometimes kills a pig ?—He does.

3326. That is not very general, is it ?—Yes ; I think that the agriculturists generally kill a pig a-year ; almost all of them. So do a great many of the miners ; but the miners do not do it so much as the agricultural labourers.

3327. Taking the advantage of the agricultural labourer over the miner, as far as keeping a pig goes, has the miner then the advantage as far as food goes ?—Yes ; much the advantage.

3328. Do you not think that the miner has more than twice the animal food in his house in the year that the agricultural labourer has ?—Yes ; I expect that, or much more. The miners live well.

3329. Do they use as much pastry in the way of pasties as the agricultural labourers ?—I should think not.

3330. (*Chairman.*) Does not a miner, considering the work which he has to do, require more animal food than an agricultural labourer ?—Yes.

3331. Should you say much more ?—Much more ; and he has much more.

3332. Have you any idea of the quantity of meat which a tut-work miner is able to afford out of his wages to his family?—No. A tut-work man's wages are more regular than a tributer's. The tributer, no doubt, gets put to a shift very tightly, because, if the speculation turns against him, he sometimes only gets a very small sum.

3333. Do you think that the miners generally have sufficient animal food to make up for the loss which they sustain by the hard work wich they undergo in hot places ?—I believe that they live very well.

3334. (*Mr. Austin Bruce.*) Do you attend agricultural labourers as well as mining labourers ?—Yes.

3335. Taking the two classes, do you observe much difference between the state of an agricultural labourer at 40, and of a mining labourer at the same age ?—A very great difference.

3336. What is that difference ?—You find that the miner looks the older man of the two ; that he would look 10 or 15 years older than the agriculturist.

3337. How soon generally does a miner's health begin to fail him ?—It depends on how early he goes to work. Some go very young to a mine, at 10 or 11, and work underground as early as that.

3338. When they begin early, does their health usually fail sooner ?—I think that, at between 20 and 30, you will find many of the miners look thin and sallow, and their muscles are not well up.

3339. Do you think that they fail earlier in proportion to the early age at which they enter the mines ?—I think so. I think it is a great disadvantage to a little child of 10 years of age to go underground.

3340. You stated that one cause of the weak health of the miner was the absence of light from his work ?—Yes.

3341. And also the presence of the smoke of candles and powder ?—Yes.

3342. The absence of light is of course inevitable ?—Yes.

3343. The evils arising from smoke, whether of powder or of candles, might be, to a great extent, removed by a free current of air, might they not ?—Yes, if you could get the current of air ; but in a long end you cannot get any air ; at least so I am told.

3344. Have you ever traced the illness of any miner to the mere fatigue attendant upon the ascent of a deep mine ?—No, never.

3345. I gather your opinion to be that it rather aggravates than causes disease ?—Yes, it aggravates it much, I think.

3346. Do you attend mines in which there are any other means of ascent than by ladders ?—No.

3347. Have you had any opportunity of comparing the health of miners working in mines where there are man-engines, with that of miners where there are only ladders ?—No. We have no man-engine near ; not in our district. I hear those who work in mines where there is a man-engine say that it is a great relief to them.

3348. Do you despair of seeing the general health of the miners improved in this district ?—I do not see how the health is to be improved, unless the climbing be lessened and the ventilation improved.

3349. If you were called to the counsel of agents, could you suggest no means of improving the general health of the men ?—Yes, I could.

3350. What would you suggest ?—A man-engine to relieve the climbing ; and ventilation of the most perfect kind which could be afforded.

3351. The latter suggestion would be made upon the belief that the most perfect ventilation is not in use ?—I believe that they do what they can. I know that there is very great difficulty in ventilating an end which is a long way from a shaft, where there is a single shaft.

3352. You also know that difficulties are made to be overcome ?—Yes, I know that.

3353. And that many difficulties hitherto considered insuperable have been overcome ?—I have no doubt that ventilation might be much improved ; but I do not see how poor mines are to be developed.

3354. Then it is a question between the lives of men and the development of poor mines ?—You cannot get over this difficulty, that in mines where they have only one shaft the ventilation, as of course must

LISKEARD.

Mr. A. Kingston.

19 April 1862.

be obvious to any one, cannot be perfect; if you put down two shafts you stop the mines at once.

3355. Then you distinctly say, as within the experience of your medical practice, that men working in mines having but one shaft are, as a body, more unhealthy than those working in mines with more shafts?—I have known in some mines, in my experience, where they have had only one shaft, that the men have complained that the air has been very poor, and that they have suffered from it.

3356. And have you observed that they did suffer?—Yes, most assuredly so.

3357. Can you remember, in the case which you have last mentioned, what per-centage of men affected by the bad air came under your treatment?—A very small proportion; very few of the men. We have not any large number of men ever under treatment who are complaining of bad air.

3358. Even in the cases of the worst ventilation?—No, certainly not.

3359. Taking the mining population of the ages between 20 and 30, is there, in your opinion, any considerable proportion of them affected by the air in which they have worked?—Yes; they have not the free action of the lungs that agricultural labourers or persons working at other employments have. I never remember being called to attend a man very ill from poor air; it is the combination; he takes some inflammatory attack.

3360. (*Mr. Fulke Egerton.*) It is in fact a case, I suppose, of weak lung, arising from various causes?—Yes.

3361. From bad air, and from muscular exertion?—Yes; and atmospheric causes.

3362. (*Mr. Kendall.*) Are the cases very rare which you have been called to attend, of men suffering exclusively from having worked in a badly ventilated end, a badly ventilated rise, or a badly ventilated pitch?—They are few. From the general mining work, they are not in the good condition in which other men of between 20 and 30 are.

3363. From the information which you have been able to get from miners whom you see, are you not of opinion that in the majority of mines in this district the natural ventilation, *quoad* ventilation, is good?—I am of opinion that it is good, decidedly.

3364. (*Mr. Austin Bruce.*) Is not the word "good," so used, a relative term?—No, I should say not.

3365. Do you mean that the ventilation in most cases is so positively good as that a man may continue to work in it without bad effects to his health?—I was once under ground, and I know that the climbing hurt me a good deal. I climbed 100 fathoms, and was very glad to sit down every 10 fathoms; it made my heart beat so violently, that it almost jumped out of my side.

3366. Do you consider the greater part of the bad health, which you have described as being almost universal among the mining population, as compared with the agricultural population, to be the effect of bad ventilation, or of fatigue arising from mounting ladders?—I believe that both combined have an influence; but I think that the climbing a long distance has a very prejudicial effect. The heart beats so violently, that the blood is thrown in upon the lungs, and you are obliged to breathe much more rapidly; and a long continuance of that, year after year, acts very prejudicially.

3367. The long practice that a Cornish miner has in climbing, of course makes him bear the exertion of climbing more easily than if he were less practised?—Yes.

3368. Do you suppose that if that climbing were performed in the open air, it would be as injurious to the miner as if it was performed in the mine?—No.

3369. Then the want of ventilation would appear to have a direct effect upon the health of every single miner who descends into a mine?—Most assuredly the want of ventilation has.

3370. Then a miner pursues his occupation, apart from the climbing, under less favourable circumstances than the out-door labourer?—Yes.

3371. Therefore, any large and general improvement in the means of ventilation would improve the general health of the whole mining population?—Yes.

3372. You have stated that many miners have told you that the air in which they worked was all that could be desired?—I have asked them this question frequently, "Are you working in poor air?" "Oh, no, Sir." And some say, "We have too much air, there is a draught." Again, others say, "We are working in very good air;" and others say, "We are working in poor air."

3373. Where the ventilation is well managed, I presume there would neither be poor air nor a draught?—That is the great difficulty to get ventilation of that kind. You find in almost every room, that if there is ventilation at all you have a draught.

3374. But not a cutting draught?—No; there would not be a cutting draught.

3375. Poor air itself is a relative term?—Yes.

3376. Would you not say, if you had to live in the ordinary air that is breathed in a mine, that you were living in poor air?—No. I should not consider that I was living in air equal to what it was on the surface. But that is not what I understood from the miners, or any one connected with a mine, to be poor air.

3377. Poor air, in miners' language, means very bad air, does it not?—It means close air.

3378. (*Mr. Holland.*) In which a candle will hardly burn?—Yes; they put the candles on the level, horizontally.

3379. (*Mr. Austin Bruce.*) Is there not, in your opinion, a great deal of air in a mine which would be unhealthy, although it would be far short of what the miners call poor air?—Yes.

3380. Do you despair of seeing ventilation in mines so improved under ordinary circumstances as to make mining a more healthy occupation than it is at present?—I hope that it will be improved; and I do not despair.

3381. Have you looked into the question of ventilation?—No; it does not fall within our province.

3382. (*Mr. Kendall.*) You have been very little underground, I believe?—Never but once.

3383. (*Mr. Holland.*) Of course there are a great many bedrooms in this country which have no chimneys?—Yes.

3384. And very often the people shut up their windows and doors, and after they have slept in the room the air in the morning is close and nasty?—Yes.

3385. In your opinion, is such a room anything like so close as a mine?—Yes; I should think that the room was closer than any of the mines.

3386. Would the quantity of oxygen be diminished in anything like the same proportion as in a mine; in such a bedroom as I have described, the oxygen would not be diminished one per cent.?—I cannot say. I know that I often go into bedrooms before the doors and windows have been opened, and the air is very impure.

3387. But such air, although sickening to the sensation and very injurious, has not its oxygen reduced by a half per cent.?—That may be so.

3388. It has been given in evidence, that in parts of the mines the oxygen is reduced three per cent. Is it not probable that in other parts of the mine it may be reduced by a much larger per-centage than one per cent?—I cannot say.

3389. It is a well known fact in chemistry, that a candle will burn without any perceptible dimness in oxygen which is reduced from 21 per cent. to 15 or 16 per cent.?—Yes.

3390. It has also been stated in evidence, that in many parts of the mines a candle will burn very dimly; so that it must be reduced nearly to that amount; and that would be seven times as much as in the bedroom we have spoken of?—I cannot speak to that at all. I am not cognizant of the fact.

3391. What is called the miners' complaint is not common consumption, is it ?—It is a sort of asthma.

3392. And a sort of bronchitis ?—Yes, as well.

3393. And also the symptoms of tubercular consumption, all mingled together ?—Yes.

3394. Sometimes one, and sometimes the other ?—Yes.

3395. I dare say you know that the proportion of deaths from consumption among young miners is less than the average ; or are you aware of that ?—No.

3396. Have you noticed that young miners die of consumption in a larger proportion than the young men of other classes ?—No.

3397. At what age does the excess of consumption appear ?—I should think between the ages of 30 and 40.

3398. Not later than that ?—It possibly may be so.

3399. Not between 40 and 50 ?—I should think 50 was late, speaking of those who have fallen under my notice.

3400. Among other persons, not miners, the deaths from consumption occur early ?—Yes.

3401. If a man survives 30, his chances of dying from consumption are reduced ?—Yes.

3402. Is not that a strong argument to show that the miners' consumption is not the same disease as common consumption ?—I do not think it is. Those men who die of miners' consumption are generally ill for years before.

3403. Does emphysema of the lungs, especially if combined with chronic bronchitis, assimilate very closely to consumption ?—Yes ; you would not distinguish them till you came to examine the persons.

3404. Have you had many opportunities of making post mortem examinations ?—No.

3405. Is not the miners' consumption slower in its progress than common consumption is generally ?—Yes, it is.

3406. It lasts three or four times as long, does it not ?—Yes ; they are home with cough and expectoration for two or three years.

3407. In common consumption, considerably more than half of those who die die within a year of the first attack ; is that the case with those who suffer from miners' consumption ?—No.

3408. Do not considerably more than one half of those who die live for two or three years ?—Yes.

3409. And many for ten years ?—I have known them live for five or six.

3410. And occasionally for as many as ten ?—I think it is very likely ; but no one has fallen under my notice that has lived for 10 years after the disease has commenced.

3411. Do not a considerable number of persons who have had pretty sharp attacks of miners' consumption recover, if they leave their employment and go to places where they breathe purer air ?—I should hardly call it miners' consumption then ; but if they get to another employment, they wonderfully improve, and live on for years and years.

3412. Do not a number of miners who, from their symptoms, appear to have consumption, if they leave their occupation, recover and get pretty well again ?—Yes.

3413. Is not that a proof that a great number of cases that appear to be consumption are not consumption ?—They are not, I believe, although a stranger looking at a man would say that he was consumptive; but if they examined him, they would think that he was not in consumption, but had that condition of lung that if you took him away from the mine and gave him out-door employment he might recover. We have had some elderly miners appointed as agents, and they have improved and got quite fat, and everything that one could desire.

3414. The Commissioners have been informed that the miners are very much annoyed by the dust ?—I never heard one complain of the dust in one of our mines.

3415. (*Mr. Austin Bruce.*) You do not think that any disease has been produced by that cause ?—I never heard of such a thing. I was not aware that we had dust in our mines.

3416. You have never heard that the dust is stated to be one of the causes of the miners' disease ?—Never.

3417. Referring to the dust caused by the use of the borer ?—I never heard one of them complain of the dust in my life.

3418. Have you never read any reports upon that subject ?—I have never seen any report of miners being injured by the dust.

3419. But have you never read any medical report in which it has been stated, that the dust is one of the causes of the miners' disease ?—I do not remember ever reading of any dust at all ; and I never heard a miner complain in 20 years about the dust.

3420. (*Chairman.*) If they inhaled dust, would not that be injurious to them ?—Yes ; it is self-evident.

3421. (*Mr. Kendall.*) In your experience of 20 years, you never heard the men complain in this district of the dust ?—Never.

3422. (*Mr. Holland.*) Have the miners much cough before they begin to spit ?—Yes ; they cough for years with very little expectoration.

3423. In those cases, is there much emphysema ?—Yes, I think so.

3424. Is not the emphysema produced by the quick climbing ?—I think it is.

3425. If a man has been breathing very poor air his blood would be deprived of oxygen, and he would, therefore, stand in need of it ?—Yes.

3426. Would not such a man be more likely to suffer than if he had been breathing pure air before ?—Yes.

3427. And be, therefore, more liable to suffer from emphysema ?—Yes.

3428. In a large proportion of the cases of miners' consumption, is there emphysema ?—I believe so ; but I have not had an opportunity of examining them.

3429. Is there very great resonance of the chest ?—Yes.

3430. You have stated that there was very little stomach complaint among the miners ?—Yes.

3431. Is there not a good deal of weak digestion among them ?—They do not complain much of that ; cases of that kind do not fall under our notice.

3432. In ordinary life, one of the commonest causes of weak digestion is poor air, especially among young children ?—Yes ; but we do not have them come in to us with anything of that kind.

3433. (*Chairman.*) Do you ever have an opportunity of making post mortem examinations ?—Never; I think I can hardly recollect a case, except through the coroner. I have tried very hard on one or two occasions, but I have failed.

3434. (*Mr. Kendall.*) Have their friends objected to it ?—Yes; they have. There are some cases that would be very interesting, and that one would like to examine.

3435. (*Mr. Austin Bruce.*) You have stated that the medical men of this district are on the most friendly terms with each other ?—Yes, they are.

3436–7. You have, doubtless, had frequent communications with them, as to the causes of the special diseases from which the miners suffer ?—No, I do not think I have ; it is much more in assisting one another in attending to the cases ; not more than there would be in conversation, I think, as to the causes.

The witness withdrew.

Mr. ROBERT DUNSTAN examined.

3438. (*Mr. Austin Bruce.*) With what mines are you connected ?—With no mine in Cornwall now.

3439. Have you had the management of any mine ?—Yes ; as many as 13 at a time.

LISKEARD.

Mr. R. Dunstan.

19 April 1862.

3440. In what neighbourhood ?—In this neighbourhood.

3441. How long have you been engaged in mining operations ?—Forty-five years.

3442. In what capacity did you begin ?—As a working boy. I worked at the dressing floor at nine years old.

3443. How long did you continue working ?—For 27 years.

3444. Since then you have been an agent ?—Yes.

3445. Have you observed any improvement since that time in the health of the miners ?—Not much improvement as respects the health of the miners.

3446. What should you say was at this moment the condition of the health of the miners, as compared with the health of the surrounding population ?—A miner cannot enjoy his health like other people.

3447. For what reason ?—From the nature of the employment.

3448. What is there in the nature of their employment that makes the difference ?—Climbing particularly.

3449. Is there anything else ?—Yes ; the foul air that they breathe, and that they are obliged to work in.

3450. In our opinion, can the climbing be got rid of ?—It is got rid of in some instances.

3451. Could it, do you think, be got rid of in more instances ?—Yes.

3452. To what extent do you think it could be got rid of ?—We consider that in an established mine, the man-engine should be employed for lifting the miners up.

3453. Have you ever thought of any other plan than that of the man-engine, and which would be more convenient ?—Yes ; but I do not think that any other plan would be applicable in Cornwall.

3454. Do you think that a man-engine would be too expensive for small mines ?—I think not. I think that a man-engine could be employed very inexpensively.

3455. What do you mean by the terms "an established mine" ?—I mean where a mine has been discovered to contain minerals of sufficient quantity to admit of its being worked to any extent. There are many mines that are very ephemeral.

3456. In all such cases, you think that a man-engine might be employed ?—I think it should be employed.

3457. In your opinion, that would get rid of a great deal of the sufferings of the miners ?—Yes ; the climbing is the great bane of the miner.

3458. Some mischief would still arise from imperfect ventilation ?—Yes.

3459. Has the ventilation been much improved within your recollection ?—Yes.

3460. Do you think that the ventilation is capable of further improvement ?—Yes, in many instances,

3461. Is the best ventilated mine that you are acquainted with as well ventilated as it might be ?—I should say that it is as well as it might be, conveniently to all parties concerned.

3462. But what do you mean by the word "conveniently ?"—It is impossible to have the mines always ventilated. You are probably aware, that there are certain shafts sunk, and the levels have to be driven to some extent before any other communication can be made ; but they must be driven to a certain extent. We sink winzes, and that gives further ventilation; but then the miners do suffer, and they must of necessity suffer, from the point where they drive off from the bottom of the shaft until they meet another point where the winze is brought down to communicate with the level they are driving, to give them ventilation there.

3463. When winzes are driven, is good ventilation supplied ?—Yes.

3464. Could no intermediate means of ventilation be applied ?—It might be done, and it is sometimes done with machines.

3465. Apart from the close ends that you have been describing, do you think that the current of air in the mines that are considered to be well ventilated is as great as it might be, or as would be consistent with the highest state of health attainable by a miner working underground ?—The current of air in well-ventilated mines is quite sufficient. Sometimes we are obliged to put doors, for it is too strong, very often; where we have several shafts in a mine, the current of air is very strong.

3466. Do you think that the majority of the men working at tribute-work are working under as good conditions, with regard to their health, as might be desired ?—Yes ; as far as the air is concerned and ventilation.

3467. Your exception applies to the absence of man-engines ?—Yes. The climbing is the most injurious, I have found it so. I have been climbing ladders now for forty-four years, and I always suffered most from that.

3468. In the case of an ordinary mine, what number of men are usually engaged in work which, in itself, you consider unhealthy ?—That would be the tut work men, generally. The tributors get the healthiest part of it; they are always working, or in ninety-nine cases out of a hundred, between communications, and where there is plenty of ventilation. It all depends upon the productiveness of the mine In some mines the tribute system preponderates ; in poor mines the tut-work is more general, because there would not be ore in sufficient quantity to employ tributors. It varies according to the quality of the mine, as well as to the extent of it.

3469. Within what limits does it vary ?—I do not think that there is any rule for it. I was in Fowey Consuls for eighteen years, and that was one of the most productive mines in the county at one time. We were 1,100 men there, and I should think that 500 out of the 1,100 were tributors. In the West Caradon Mine, that I managed for eleven years, we had 500, and about 200 of them were tributors.

3470. In each case the majority consisted of tut-work men ?—Yes, I think so. It must be a very good mine where the majority are tributors.

3471. Of the tut-work men, how many were working in places which, in your opinion, were more or less unfavourable to good health ?—That varies, because if I commenced to drive a level to-day from a given shaft, the further I depart from the ventilation, and from the pure into the impure air, I create impurities, I destroy the oxygen ; and the further I go, the worse the air is.

3472. The moment you leave the best ventilated part, you begin to suffer, however small that suffering may be ?—Yes, you continue to grow worse.

3473. How many tut-work men, in your opinion, are working in places less favourable to health than those in which the tribute men are working ?—All the tut-work men.

3474. You think that all of them are working, more or less, in places unfavourable to their health ?—Of necessity.

3475. You say "of necessity;" that means, I suppose because they are not reached by the ordinary means of ventilation, which is adopted in the district ?—They are reached by the ordinary means.

3476. But not to the same extent as the tribute men ?—No ; because the tributor is working between two chimneys, as it were, or between the channels of communication.

3477. (*Mr. Holland.*) In your mine, do all the tut-work men work in such air that you would improve it if you could ?—Yes, except those who work in an immediate draught; I mean all those who are working at a distance from a communication. A man may be working in pure air to-day, and a communication may be made by means of a winze, and he will be in a better part to-morrow ; and another, who was in the best air six months ago, may now be breathing impure air.

3478. (*Mr. Austin Bruce.*) Do you consider that if the condition of the air in which the tutwork men

are now working were a fixed condition that means would not be taken to supply them with as good ventilation as the tribute men enjoy ?—Yes; it could be done.

3479. And the reason why they are not so well supplied is, that their condition is constantly changing ?—Yes.

3480. Do you consider that all the means have been exhausted by which ventilation can be provided for the tutwork men ?—No, certainly not.

3481. Even in the best ventilated mines ?—No.

3482. What would you do to improve the ventilation of the closed ends ?—You could erect an engine, if you pleased, to drive air to them.

3483. Do you believe that in most cases that could be done at an expense which would not be injurious to the adventurers ?—It is done now in many instances.

3484. Then is it from a want of an intelligent appreciation of their own interests that these ventilating engines are not employed by the adventurers ?—I should not very well like to answer that question, because I should be, as it were, condemning the intelligence of those parties.

3485. Do you believe that a good system of ventilation would be as much for the interests of the employers as the employed ?—Yes, and more so. No man can do half the work where the air is bad; not one quarter of it.

3486. Do you think that good ventilation is nearly in all cases within the reach of the employers ?—Yes.

3487. And, therefore, if they neglect it, it is from want of understanding the advantages of good ventilation ?—I think that if the adventurers generally understood practical mining better, they would, to secure their own profit, adopt means to promote the interests of the miners.

3488. Do you think that agents are often interfered with by the adventurers in their plans for the improvement of ventilation ?—I never was.

3489. Do you think that other agents are ?—I cannot think for others.

3490. In the mines in which you have been engaged were there no close ends that were insufficiently ventilated ?—Yes. I have worked in places where I have been obliged to keep the candle six feet behind me, for a man can breathe where a candle will not burn.

3491. Can a man breathe where a candle will not burn without injury to his health ?—Certainly not.

3492. (*Mr. Kendall.*) As I understand you, the tut-work is very different from the tribute-work ?—Yes.

3493. Tribute-work is all ventilated; tut-work is not ?—Yes.

3494. But in well-conducted mines, is not the air generally forced where it is required into the tut-work ?—Yes.

3495. But that is generally very inferior, is it not, to natural ventilation ?—Yes.

3496. Your experience leads you to think that, with reference to ventilation, there is sometimes false economy, and a want of due consideration for the miner's health ?—Yes.

3497. And great improvements are required ?—Yes.

3498. (*Mr. Holland.*) Do not the adventurers always object to every expense they can avoid ?—No.

3499. (*Mr. Kendall.*) As far as your experience goes, do not the adventurers listen to the advice of their agents ; and have you ever known a case in which, when the men complained of bad air, and it was ascertained that there was bad air, the agent has refused to do his best to remedy it ?—Never.

3500. Is it the common habit to say to a man, "If you do not like to do that, we will find somebody that will" ?—Never.

3501. (*Chairman.*) Suppose that the men complain of poor air, what does the agent do ?—He takes steps to remedy it.

3502. In the meantime does he stop the work ?—Sometimes he is obliged to do it.

3503. But not always ?—No.

3504. What steps does he take to introduce better air ?—He employs some of the machines that I have spoken of; sometimes a fan machine; at other times it is worked by a box.

3505. Then the work must be stopped, must it not, until he has provided those means ?—Yes.

3506. Do the tut-work men receive any pay when the work is stopped ?—Sometimes they have none, and sometimes other places are provided for them in the meantime.

3507. But sometimes they have no pay to receive ?—No.

3508. Do you think that the men who are dependent for their livelihood on their labour would rather go on driving in poor air than leave off ?—They would rather go on as long as they can.

3509. As long as their powers would permit them to do so ?—Yes.

3510. You have said that the levels must be driven until you come to where you can either put down a winze, or come to another shaft ?—Yes.

3511. What means would you use there to introduce air ?—The best means is a waterfall, where you can command it.

3512. But suppose you could not command it ?—Then you must drive a machine, either by manual labour or by an engine.

3513. Do you mean an air machine attached to the main rod of the engine ?—Yes.

3514. Does that exhaust the air, or introduce fresh air ?—We like to drive fresh air in.

3215. Do you convey it through iron pipes or zinc pipes ?—Zinc pipes are the best.

3516. Do not zinc pipes corrode very much ?—No. Wood is porous, and that takes up a great deal of air.

3517. Can you mention any mines about St. Austell, or in the neighbourhood of Redruth, where these engines are at work ?—They are, more or less, at work in every mine.

3518. Have you any mines where we could see the machines at work pumping in the air ?—No.

3519. How long is it since you visited any of those mines ?—I am constantly visiting them ; but not with a view to look after that part of it. I go to inspect the mines, to see what they are worth.

3520. For the brokers ?—No ; for the adventurers.

3521. And then you report to the adventurers ?—Yes.

3522. When you are sent to inspect a mine by any adventurer, do you report to him as to the ventilation and the working ?—Yes ; I report upon the whole working of the mine.

3523. As well as the value of the mine ?—Yes.

3524. In your experience, as a captain, do you think that the health of those who are working in the mines is worse than the health of those who work above ground ?—Yes, certainly ; always.

3525. By what, in your opinion, is that caused ?—It is caused by three things. Principally it is caused by climbing the ladders ; a deep mine is very injurious for that ; and it is caused by breathing impure air ; and it is caused also by taking frequent chills and colds. When a miner gets to work his work is very laborious, and he gets very hot, and he then, of course, cannot continue at it; he gets into a very high state of perspiration, and goes back to rest himself, and then there is a cold chilliness in all that is about him, and he takes cold. Miners are seldom free from colds, and that brings on an affection of the chest ; and there is a complaint which is peculiarly known as the miner's consumption; it brings on an asthmatical complaint, and an affection of the heart, and two or three things altogether, which seem to cause a peculiar miner's complaint.

3526. You say that they catch cold from waiting ; do they ever stand upon the ladders before they come up ?—They are obliged to do that, for no man can climb 100 fathoms right away.

3527. Do they wait above the adit level on the

ladder ?—Yes, some do ; but that is their own fault. They are not allowed to come up generally. There must be discipline where there are 400 or 500 men.

3528. But they do come up and wait there, do they not ?—Yes ; I have done it myself.

3529. That is because they would be fined if they came to the surface ?—Yes.

3530. By what means does a miner ascertain what the time is ?—He can tell by his candles.

3531. Is no signal sent down to him ?—No.

3532. When a miner has completely blasted his holes, which I suppose he does generally near the end of his time, where can he go ?—It is a great folly to detain him. If a man is working in a close place he blasts his holes, and then the place is not fit to go into for hours, for it would be very injurious to breathe the hot powder smoke. It is, therefore, great folly to force a man to do it when he can help it. I could overcome that by giving men a fair price for their work, and let them get as much as they can get.

3533. Might not a miner be allowed to come above ground, and go to some place and wait ?—He would not want to wait ; he might come up and put on his clothes, and go home ; there is no object in keeping him waiting.

3534. But what security would you have that a miner did the full extent of the work he had undertaken to do ?—You do not want any security if a man is not paid for more than he gets. We have what is called stent ; and the meaning of that is, that a certain portion of work is set to a man, and he has a certain amount paid to him for doing it ; so whether he does it in six hours or eight hours it matters not to the miner.

3535. Then why do you suppose that the rule is so very general that the miners are not allowed to come to grass ?—I have no supposition upon the point ; I know it.

3536. But why should it be so general ?—I can hardly tell. I never could conceive the reason for it. I know that there is no good in it.

3537. Is it not injurious to the men ?—Yes.

3538. (*Mr. St. Aubyn.*) The men are not paid by the time, but by the piece ?—Yes.

3539. Then what is the object of fining them for not keeping time ?—I suppose it is just this, that if you have a very expensive mine with three or four steam engines going, and there are agents and a whole staff of people to be supported, that amounts to a certain amount of dead weight upon the mine, and you want to get out of the men as much labour as you can ; and it is always the case that men differ from one another ; some men are not very industrious. Suppose, for example, we had four engines working, and burning 1,200 tons of coal in a month, then there would be agents to the extent of 50*l.* a month, and all the other expenses to meet, and machinery to keep alive. You would want some labour to be done ; and suppose the men did not labour at all, but made it an object always to do this, sometimes they might come to a change in the ground, and they would wait ; they would not want to go through that piece of ground, as it would want an increase of the price.

3540. Because it was more difficult to work than they expected ?—Yes.

3541. While the men are paid by the piece is it not more profitable for the adventurer that the men should do their work quickly rather than slowly ?—Yes.

3542. Then what security would you have that the men while underground were working, and that they were not sitting down idle ?—None whatever ; but a practical miner can tell whether the proper amount of labour has been done.

3543. For example, you could tell nearly what a man ought to do ?—Yes.

3544. (*Chairman.*) That is the business of the underground captain, is it not ?—Yes.

3545. (*Mr. St. Aubyn.*) But if he is not present how is he to prevent a man sitting down for the last half hour that he is down ?—The common rule is, when the agent comes in, for the men to sit down ; they never work while he is there ; he would want to look at the lode, and see what the work was worth ; and the common practice is, that the miners, who are a very civil class of men, as soon as the agent comes in, stop their working, and they go back for him to examine the work.

3546. (*Chairman.*) Suppose there was half an hour or a quarter of an hour's law given before they were allowed to come up, do you think that would be abused ?—It would amount to the same thing precisely. I see no good whatever in keeping a man from the adit between the adit and the surface till the bell rings ; there is little good in it ; it is not carried to the same extent as it used to be.

3547. But it is carried out to some extent ?—In some mines I dare say it is.

3548. (*Mr. St. Aubyn.*) Self-interest will generally induce a man to work as long as he can, will it not ?—Yes ; and the great point is to give a man as much work as he can do in a month, and a fair price for his labour ; that is all that is necessary.

3549. You stated that a rule was adopted to restrain as far as possible any idling in the bottom of the mine ?—In the best regulated mines, where the agent is not cramped by the adventurer, and where the agent is an intelligent man, he gives a fair price for the work that he has to let, and gives a man as much work to do as he can during the month. Then a man, if the system of what is called the monthly allowance is not adopted, thinks that he may get 4*l.* or 5*l.*, and there is no restraint upon it ; he is allowed, by dint of his own skill and manual strength and industry, to do what he can, and then he pursues his labour with a greater degree of interest. But the other system, where the monthly allowance is made, entirely destroys that.

3550. Will you be good enough to explain what you mean by the monthly allowance with reference to tut-work ?—The monthly allowance is of this kind. When a man comes into a mine and asks for work, he also says, "What do you allow ?" "We allow 3*l.* or 3*l.* 5*s.*" Then if the adventurers are close upon the agent, the agent is not expected to allow a man to get more. And I mean that that system destroys the energies of the men, because the miners are a calculating body of men, and a miner says, "I must not get more than 3*l.* or 3*l.* 5*s.* I may as well get it easy as hard." But if the captain or the manager is unshackled, and he is allowed the full exercise of his own judgment in conducting the whole of the operations of the mine, he would do as I have said. I will just give the Commissioners my own history upon this matter. When I have been asked this question, "What do you allow ?" I have said, "Nothing ; I make no allowance. I fix the price upon the work, and you may get as much out of it as you can. You may get 3*l.*, 4*l.*, or 5*l.* ; there is no stint to your getting." Then a man goes to work, and uses his best skill and his best energies.

3551. What is the price per fathom that is paid to the pairs ?—I have known it vary from 7*s.* 6*d.* to 30*l.* a fathom, according to the hardness of the ground.

3552. And nothing else ?—Yes ; there are other circumstances. For instance, poor air would come into consideration ; but the hardness is mostly the cause.

3553. (*Chairman.*) If the miners are working in poor air is that taken into consideration, and is a larger allowance made to them ?—You must give them more, or they could get nothing. They could not do half the work that they otherwise could do.

3554. Then it would be clearly for the interest of the adventurers that a mine should be well ventilated in order that the men might do more work ?—Yes ; but take what care you can, the men must of necessity be exposed to foul air.

3555. (*Mr. Fulke Egerton.*) I think you stated that you thought it would be advisable in all old established mines that there should be man-engines ?—Yes.

3556. Is not the expense of the kind of man-engines to which you have referred very considerable ?—I am not aware that it is.

3557. Do you happen to know what the expense of a man-engine is in a mine, such as there are in the West, 300 fathoms down ?—No ; I do not know the expense of a man-engine to that extent. It does not require great power, I think.

3558. (*Chairman.*) You are probably not aware that the cost has been stated to the Commissioners to be 2,000*l* ?—I should not think it was so.

3559. (*Mr. Austin Bruce.*) Do you consider that the wire rope of the usual engine employed in collieries could be adopted in this district ?—The wire rope is used in this country already.

3560. But it is not used, is it, for drawing men out of a mine ?—No.

3561. (*Chairman.*) Do you know of any mine in this district where skips and wire ropes are used to carry the men up and down ?—No ; I know of no such thing in this county.

3562. Do you know the South Francis Mine ?—I do know it.

3563. Do they not use them there ?—If so, it has been a very recent introduction, and the men may ride up in it ; but I inspected the mine a short time ago—at all events some two or three years since—and they had not got it then.

3564. (*Mr. Fulke Egerton.*) Do you know any reason why those engines and the wire ropes should not be adopted in most of the mines in Cornwall ?—I do not think that our shafts are adapted for them.

3565. Is that because they are not wide enough ?—No ; I do not know that. Our perpendicular shafts would be wide enough, but they have never been constructed for that purpose.

3566. (*Chairman.*) Have you ever visited any collieries to see the way in which the men go up and down in skips ?—No ; I have been mostly after lead and copper.

3567. A man-engine, I presume, is only applicable where the shaft is perpendicular ?—Yes ; but it might be used diagonally.

3568. But not where there is a curve in a shaft ?—No ; it must be straight.

3569. Are there mines in which they have followed the lode ?—Most of our shafts are like where they follow the lodes, and the lodes are crooked.

3570. In those cases a man-engine could not be very well used ?—No.

3571. Some expense must be incurred in order to adapt the shaft for the use of a man-engine ?—Yes ; but I think that when a mine is opened, and there is a sufficient prospect of the mine becoming a lasting and productive mine, it would pay handsomely to sink a shaft for the purpose.

3572. Have not many of the large mines been opened for some time, and yet are not productive ?—Certainly; but there are very few men employed comparatively in the unproductive mines. A man-engine should be always put into the productive mines.

3573. In a young mine, after the shaft has been sunk and the men are driving a level, do you think it would be advisable to put up another shaft, or how would you provide air ?—By a machine for the purpose attached to the engine.

3574. When the late workmen are boring a hole, how many holes can a pair drive in hard ground ?—I have seen rock of such a kind that it would take two men the whole of eight hours to bore 12 inches.

3574*a*. In some kind of rock would it be possible for a man to drive as much as three holes ?—Yes, and six holes.

3575. But if the air was bad what number of holes could he then drive ?—If the air was very bad he might go in and bore two before he blasted, and when he had done that he might leave.

3576. In changing the cores at the hour of changing may the men leave their work below, before the other men go down ?—Yes, and they do. They generally calculate to blast on leaving, and then of course there would be an hour before it would be fit for any person to go in again, and then the pair manage to come up, and the other pair would be going down.

3577. Do you consider that the miners do suffer in their health generally ?—Yes, and they are badly paid too as a body.

3578. Are the miners badly paid ?—Yes, as a body they are.

3579. Do you think that they get sufficient food, considering the work they have to do ?—No, I do not, very often many of them.

3580. Many men are working in low levels in a hot temperature, but they do not get sufficient food to make up for the waste ?—Nor do they get the food that their appetite requires, because miners have very delicate appetites.

3581. What do you think that arises from ?—From the foul air.

3582. So that they are not able, even if their wages allowed it, to take sufficient nourishment to supply the loss ?—Yes, they would ; but it must be a better class of food than what the labouring people get generally. If a man has a family the wages allowed generally are not equal to the price of provisions.

3583. What do the tut men receive after all deductions are made ?—I suppose they get from 3*l.* 5*s.* to 3*l.* 10*s.* a month, which would be a fair average.

3584. What is the amount of the house rent which they have to pay out of that ?—That is daily ; the firing is daily ; and they are exposed to a great deal of imposition in many ways. They are only paid once in a month, and they go in debt to the little shopkeepers, and they pay the dearest for everything.

3585. Are they not one month in arrear ?—Yes.

3586. And a man just commencing to work must work for two months before he receives his pay ?—Yes.

3587. During the first month does he have credit ?—Yes.

3588. In some mines they allow subsist money, do they not ?—Yes, in some mines.

3589. If not, the miner must deal on trust at the shop ?—Yes.

3590. You have stated that the men catch cold ; do they take cold on account of the bad changing houses ?—I should think not ; they are generally pretty well provided.

3591. Are their changing houses good ?—I think so, generally. In large established mines we have drys, and men are put there to dry the clothes for the miners.

3592. Are those drys attached to the engine house?—Certainly not.

3293. Do you think that there are no instances of that kind ?—There may be isolated cases ; but generally there are drys built for the purpose.

3594. (*Mr. St. Aubyn.*) You stated at the beginning of your evidence that the climbing up of ladders was one of the principal causes of the bad health of the miners ?—That is the great cause. I have known men in West Cornwall who died on the ladders. They have come up to the top of the ladder, and then dropped down dead suddenly from disease of the heart brought on by climbing.

3595. In your opinion would the adoption of a man-engine, wherever it was practicable, entirely prevent that one cause of illness ?—From that particular source.

3596. The obstacle in the way of adopting the man-engine, I think you said, was the expense ?—No.

3597. Then what are the obstacles in the way of adopting a man-engine ?—I think it is for want of preparing for it in the outset of infant mining. It requires a given condition of shaft ; and if the adventurers were wise as they ought to be, they would prepare for that in the outlay of the mine.

3598. It being necessary that the shaft should be straight ?—Yes.

3599. Where the shaft follows the course of the lode, and there are curves, I suppose it would be impossible to have it ?—No.

LISKEARD.

Mr. R. Dunstan.

19 April 1268.

3600. Do you think it would pay if you were to sink a shaft straight down, and drove levels from it merely for the purpose of having a man-engine?—Yes; and I could give statistics that would show clearly that it would in any mine of any considerable extent, even now, pay for itself in 12 months, from the amount of labour that would be saved.

3601. You are acquainted of course with many mines in this county, and you know a great many mines where there are not at the present time man-engines?—Yes; there are very few in the county.

3602. Where you think there might be?—Yes; there ought to be man-engines in all this district.

3603. In the case of sinking a shaft in a new mine, at what depth from the surface should you think it necessary to adopt a man-engine?—I think that a miner ought not to be required to go further than 100 fathoms down without a man-engine.

3604. Why do you fix upon that particular limit?—I suppose it is mostly from this: I know from my experience, having begun mining so soon, that we did not call 100 fathoms very hard work to get up, but I know that I should find it so now.

3605. Would it not be less hurtful to a miner if he had a man-engine, even at a smaller depth than that; for instance, even at 60 fathoms?—Yes, quite so; or at 50 fathoms.

3606. You would think it a good thing, and that it would pay, to have a man-engine at so small a depth as 50 fathoms?—Yes.

3607. (*Mr. Fulke Egerton.*) You think that the best way of working a Cornish mine would be to do as they do in the coal districts; that is, to sink a shaft, and take the men up and down by some mechanical means instead of by ladders?—Yes, to bring them up; the going down does not hurt them.

3608. (*Mr. St. Aubyn.*) Do you know of any mines where the men are brought up by the means either of kibbles or of skips?—I do not. The men have a great objection to come up in kibbles.

3609. Might not some kind of basket or chair be made which they could be drawn up in comfortably?—I dare say it might be, but I should prefer a man-engine. I should not like to trust myself in a skip. I would rather come up by the ladders.

3610. Why should you mistrust the skip?—The chains break so very often.

3611. Are you aware that the chains are used in mines in other parts of England?—Yes.

3612. Do you think that they frequently break?—Yes.

3613. Do you know that as a fact?—Not from my experience; but the papers show me that there are many accidents; but we have fewer accidents in Cornwall than anywhere else.

3614. (*Chairman.*) Are you aware that in some instances, when man-engines were first introduced, the men were afraid of going up in them?—I think it is very likely they were.

3615. But when once they had tried them, their dislike ceased?—No doubt of it.

3616. (*Mr. St. Aubyn.*) If it were proved, after a certain time of trial, that the skips were not dangerous, do you think that the men would then object to going down in them?—They would get accustomed to it, no doubt; men get inured to danger. But the great point is to provide the means; not to cultivate the nerves to enable a man to face danger, but to protect him from danger.

3617. How long does it take to bring the men up in a man-engine?—Not many minutes. I should think that a man would come up in ten minutes in a man-engine; whereas it would take him two hours by manual labour to come up the ladders.

3618. Have you ever made a correct calculation of that?—No.

3619. What length of time does it take a man to come up by the ladders in any mine that you are acquainted with?—Par Consols is something about 240 fathoms deep, and it takes them an hour to come up; no man ought to come up 220 fathoms in an hour; it ought to take him an hour and a half.

3620. How long would it take him to come up by a man-engine?—Ten or fifteen minutes.

3621. And that would be done by no kind of risk or fatigue?—Yes.

3622. How far does he come up each lift?—Twelve feet.

3623. (*Mr. Fulke Egerton.*) Is there any danger of any kind connected with man-engines?—I think not; there would be danger if a man put his head back, and did not stand in his proper position. If he was caught under the chamber he must be crushed.

3624. (*Chairman.*) It would be necessary for a man to be very attentive to what he was doing at the time?—Yes.

3625. Do you think it desirable that any provision should be made when the women are working on the surface to enable them to work under cover?—They are generally under cover; but there is some work that they have to do when they cannot be under cover; but generally they are under cover.

3626. Have they any room to go to to eat their meals in, or should any provision be made for that purpose?—That might be done; but then they have generally a place to go to.

3627. Are they not obliged to go to the smith's shop, or to some place where the men are?—They are not obliged to go there.

3628. Generally speaking, in mines, you say that there are some places for them to go to?—Yes, in the mines that I have managed.

3629. And also in the mines that you have inspected?—Yes, in the mines that I have inspected as well.

3630. Is there anything objectionable that you see in the employment of women on the surface?—I think it is very desirable to get better employment for them; but they are very useful to us, and it is much better employment for them than they would get in the factories; they are very well taken care of, they are well paid, and generally are well behaved.

3631. Do you think that they are well-conducted?—Yes; I know that they are, as a body, well-conducted.

3632. I suppose it is only in youg mines that there is but one shaft?—Some mines are worked to a considerable depth without more than one outlet; but it is never safe to do so. In well-conducted mines we do not allow the men to travel through the shafts; there is a private footway on purpose for them.

3633. When there is only one shaft, it is divided between that and the ribbles, is it not?—Yes; and then there is an engine working up and down which makes it dangerous for the men to travel through. All mines should have a private footway apart from all the engines.

3634. So that if any obstruction happened in that one shaft the men would have a way to retreat?—Yes.

3635. Are the shafts lined with wood?—Yes; but some of the footways in them are very bad. The ribbles falling away knock away the casing, and make large holes, which render it very dangerous.

3636. That is, if any material were to fall down and break through the division, it might endanger life?—Yes; many men have been killed by it.

3637. Is there any security that the ladders are in good condition?—Sometimes the ladders are injured by the falling away of the kibbles.

3638. Is there any periodical inspection of the ladders?—Not that I know of.

3639. All the bars are made of iron, are they not?—No; they are made of wood.

3640. If made of wood, are they not liable to rot and to break?—Yes; they wear very thin, and then break.

3641. Then, of course, that is very dangerous for the men?—Yes, of course it is; and men fall off the ladders sometimes.

3642. How does that happen?—We can hardly tell that. Perhaps one or two of the staves are broken,

and a man coming down, and not holding on to the stave above, has a sudden jerk and goes away.

3643. Do you not think that there should be better security, and that the means by which the men go down or come up should be improved?—I think that the footways are very often neglected.

3644. (*Mr. St. Aubyn.*) Is it not the business of the underground captain to look after the ladders?—Yes, it is; but when you have only one shaft for the engine-cradle and the kibble, there is not sufficient room, very often, to make it a good and a safe footway.

3645. (*Chairman.*) You would recommend in any mine that there should be always a separate footway?—Yes; there should be a separate footway; a mine is not safe without it.

3646. Do you suppose that many of the shafts and footways in the mines of this county are in bad condition?—I know some that are.

3647. And those ought to be specially inspected?—Yes, they ought to be inspected.

3648–78. Do you think it is desirable that the Commissioners should enquire into that point?—I do not know the object of the Commission exactly, but it is for the safety of the men that it should be enquired into.

LISKEARD.
Mr. R. Dunstan.
19 April 1862.

The witness withdrew.

Adjourned to St. Austell, at Ten o'clock on Monday next.

REFORM CLUB

ST. AUSTELL.

Monday, 21st April 1862.

PRESENT:

The Right Hon. LORD KINNAIRD, K.T.
The Hon. A. FULKE EGERTON, M.P.
NICHOLAS KENDALL, Esq., M.P.
H. AUSTIN BRUCE, Esq., M.P.
JOHN ST. AUBYN, Esq., M.P.
P. H. HOLLAND, Esq.
RICHARD DAVEY, Esq., M.P.

THE RIGHT HON. LORD KINNAIRD, K.T., IN THE CHAIR.

Mr. WILLIAM WALE TAYLER examined.

3679. (*Chairman.*) You are a Fellow of the Royal College of Surgeons, and a Licentiate of the College of Physicians of Edinburgh?—I am.

3680. You have resided for a long time in this district?—Twenty-four years.

3681. And you have been in the habit of attending miners for how long during that period?—During the whole of that period.

3682. Will you state to the Commissioners your observations with regard to the health of the miners during that period?—In the early portion of that period there was a great deal of sickness among the miners; there was a great deal of heart disease and consumption.

3683. Of what mines are you now speaking?—The Fowey and Par Consols mines. But of late years sickness has very much decreased; in fact, I promised to bring two persons here to-day who are suffering from consumption, and those are the only two decidedly bad cases which I have found in the whole district. They are not able to attend; they are too ill; they are confined to their bed.

3684. Out of what number of miners is that?—I should consider that on the average my district comprises about 350.

3685. In the two mines?—Yes. There is another mine, the West Fowey Consols, which is a very small mine at present, I should call the number 350 altogether.

3686. Are these men working underground?—Yes, all underground.

3687. Are you the only medical practitioner who attends at those three mines?—No; Dr. Pace has a greater portion of them than I have. I attend about 350, and I suppose that he attends about 550, or something like that on a rough calculation.

3688. How are they divided?—Into separate districts; the surgeon of one district does not at all interfere with another.

3689. It is according to the district in which the miners reside?—Yes, a line is drawn between the two.

3690. Without regard to which mine they work in?—Yes; it is divided into the east and the west district.

3691. With regard to the state of disease in the first period to which you refer, was that consumption, or heart disease, or stomach disease?—Principally disease of the lungs. I should say that there were double the number of cases of disease of the lungs to heart disease.

ST. AUSTELL.
Mr. W. W. Tayler.
21 April 1862.

3692. In your opinion, by what was it occasioned?—A great deal of the disease, no doubt, was hereditary; a great deal of the disease was also from the nature of the employment from climbing ladders. The Fowey Consols mine was in some parts very deep indeed; I think nearly 300 fathoms deep, and very hot. Another thing is that the men were in the habit after climbing, frequently almost in a nude state, of running across the ground to the changing house, and then walking four or five miles to their homes. Since then they have for the most part resided in the immediate vicinity of the mines.

3693. You say "running across to the changing-"house," are the changing-houses of these two mines to which you have referred, at a considerable distance from the footways?—Not a considerable distance. I forget about the changing-house then, because there has been an alteration. I suppose that the changing-house then was very near the principal shaft; the new shaft for the man-engine, as it is termed, has altered that. I suppose that it is at a little distance from the changing-house.

3694. Have you been into the present changing-house?—I do not think that I have.

3695. Do you consider that the nature of the changing-house has at all to do with the health of the men?—No, I do not think that it has.

3696. You do not think that in changing where it is open and exposed to the weather, it would be liable to give them cold?—It would if it were open and exposed to the weather. I have seen the changing-house at Par Consols; I do not think that that is open to the weather.

3697. Supposing that there was a changing-house where the roof was very low, where instead of windows there was nothing but openings, where it was exposed to the draught, and where it was badly ventilated, would it, in your opinion, be likely to affect the health of the men?—I should think that it would certainly be likely to give them cold.

3698. Would they be affected at all in their health by the dust from their clothes?—No, I think not; but there is one point which I forgot to mention, and I think that it is a very important one, namely, that

the miners, in working, necessarily inhale a great deal of small particles of copper.

3699. That is to say, that when they are boring at a dry end you think that they inhale the dust from it?—Yes, and that is injurious. A miner was telling me that he suffered so much in that respect, that he used to avoid opening his mouth, and breathed entirely through his nostrils, and he found a quantity of dust accumulated in his nostrils through doing so, which would otherwise, as he imagined, have gone down his throat.

3700. Is that miner in the district now?—Yes, he suggested that it would be a very good thing if the miners were all to wear moustaches, that it might very much prevent the dust from entering the throat.

3701. Do none of them wear moustaches as a general rule?—I think that some of them do so, but not as a general rule.

3702. And you think that it would be the means of preventing dust from entering the throat?—Yes. It is very odd that the miner's breath should seem to be so strongly impregnated with copper; you can smell the copper as distinctly as possible; at times I have noticed it in the surgery, so that they must inhale a great deal of it.

3703. And it must be injurious?—Highly injurious, and it produces greatly bronchial affections.

3704. (*Mr. St. Aubin.*) That comes from the breath, and not from the clothes, I suppose?—Not from the clothes at all.

3705. You are sure that it comes from the breath?—I am sure of it.

3706. (*Chairman.*) You say that the heat at the bottom of the mine is very considerable; I suppose that you have no means of knowing the highest temperature at the bottom of those two mines?—I have no means.

3707. But would working in that heat in itself be injurious?—I do not think that it is, because I will show you two men, one of whom is 66, and the other is 57, and they can speak for their comrades; they have worked in the deepest part of the mine for many years, and they do not seem to consider that it is injurious.

3708. Working in that temperature, I suppose, must be attended with loss of weight?—Yes, a great loss of weight.

3709. Have you ever known or have you any information as to what has been lost in weight by a man working in that way?—No, I have no idea of the amount; I have never had an opportunity of ascertaining it.

3710. I suppose that they require an additional amount of good food to make up for the loss of that weight?—Yes.

3711. Do you think that what the miners working in that depth are able to earn is sufficient to provide them with an amount of animal food to make up for the loss sustained in working in those hot mines?—I think that, as a general rule, a miner's wages, that is to say, the wages of a tributer, are very uncertain; it must be so from the nature of his employment; it is a speculation.

3712. Therefore when he is not earning he must have less food?—He must have less food.

3713. With regard to the tut-work men, do they work in that hot temperature?—I suppose that they are not exposed to so much heat as those who are working in the deep passages, or whatever they may be termed; but I do not know much of the interior of a mine.

3714. In examining any of your patients, have you ever put the question to them as to the amount of food which they have; whether it is sufficient to keep up their strength; and can you tell us the amount of food which they obtain?—The miner unfortunately does not eat much animal food,—not the quantity which he ought to eat,—because the diet of the country is principally pasties; they make almost everything into what is termed a pasty, and they prefer that.

3715. Will you describe what the pasties are composed of?—Pasties are composed of a crust of flour and various kinds of vegetables, potatoes, and onions, and apples, and a very little meat, all combined together very frequently.

3716. In your opinion has that description of food sufficient nutritive qualities in it to make up for any great loss of weight by the exertion incident to working in a hot mine?—I think that they ought to eat more animal food, but I do not think that you could prevail on them to do so. I think that they prefer the food which they have been in the habit from their childhood of partaking of; whatever their wages might be, I do not think that they would alter their diet. I have often remonstrated with them upon the small quantity of animal food that they consume.

3717. In your opinion, they do not consume a great amount of animal food?—No; I should say not one-half so much, taking the average, excepting in some very bad labouring districts, as the agricultural labourers, not, for instance, the Dorsetshire labourers, or some others, who have been prominently brought forward; but taking the average, I do not think that they consume so much animal food, and in fact they do not wish to do so.

3718. When they return home after working at the mine, from your own knowledge, can you say what they have then?—That is their principal meal; they are very fond of fried bacon and eggs, then they have what is called a supper, and they generally do not eat pasties at that time; it is more miscellaneous, broth and vegetables and bacon, and of course some meat.

3719. That is their principal meal?—That, I should say, was their principal meal decidedly on a week day.

3720. And it does not comprise much meat?—The meat is very small in proportion, it is not so much as it ought to be.

3721. Can you give the Commissioners any information as to how we could ascertain the amount of meat which ordinary miners, as a general rule, consume?—I think that it could be ascertained by taking the butchers in either of the towns, and by making a calculation of the number of butchers, and the quantity of meat which they sell, and the number of men; I made a rough calculation once, and I was quite astonished at the small quantity of animal food, considering the population.

3722. But your opinion is that, considering the work which miners do, it would be very desirable that they should have more animal food?—Yes.

3723. With respect to the air, do you think that working in a bad end with poor air is a cause of the illness of the miners?—Undoubtedly, that is one cause.

3724. What effect does that produce?—It lays the foundation of disease; it affects the lungs, and no doubt produces consumption.

3725. Has a miner ever described to you the effect on his feelings of working in poor air?—No, I cannot say that I recollect any instance of it.

3726. Another cause which has been stated to the Commissioners as being injurious to the miners, is the climbing of ladders; what is your opinion upon that point?—That is highly injurious, and that, I think, is the principal cause.

3727. Is a man climbing a ladder differently affected if he has been working where there is plenty of air, than if he has been working in a poor end; does he feel a different effect?—I can hardly answer that question.

3728. None of your patients have made any statement to you upon that point?—No; I think that there are two men who will be able to answer that question much better than I can.

3729. What is the general effect of climbing a ladder?—It is calculated to produce enlargement of the heart.

3730. Does it produce any other effect—does it affect

the lungs, for instance ?—Yes, it also lays the groundwork for consumption in many instances.

3731. Have you ever had an opportunity of making a post-mortem examination ?—I never have. I have been very unfortunate in that respect; it is very rarely that it is to be obtained.

3732. Will you state to the Commissioners how you judge that the effect of this climbing is on the heart—does it produce disease of the heart ?—It gradually produces it. Of course, if you tax any muscle beyond its proper strength it must produce disease, and the muscles of the heart being exercised beyond their proper power, become diseased.

3733. How does that extend to the lungs ?—Sometimes it does not extend to the lungs ; sometimes it causes disease of the lungs separately.

3734. Sometimes they are suffering merely from heart disease ?—Yes ; and we have had a great deal of it ; but since the introduction of the man-engine it is greatly on the decrease.

3735. Have you had cases of sudden death occasioned by heart disease ?—Very few.

3736. Do you know of any case where, after you have had a patient brought to your notice affected in the way you state, by heart disease, it has been perfectly cured by leaving the mine ?—Yes, they have been perfectly cured, and have resumed their occupation at the mine.

3737. And was their return to work attended with any recurrence of the same symptoms ?—There is a man coming here who had extensive heart disease. He ceased from working for several years and resumed his labour at the mine, but he found that he was getting worse—that his old disease was recurring, and he gave it up.

3738. Is he now perfectly cured ?—I should say that there are still the remains of the disease; but he does little light jobs at the mine, and works as a gardener.

3739. But he has difficulty in breathing ?—Some slight difficulty is still experienced, but very slight.

3740. You say that, compared with the amount of suffering experienced by the miners some time ago, there has been a considerable alteration for the better? —Considerable. I recollect that there used to be from 15 to 20 persons receiving permanent pay from the mine on account of heart disease and consumption, and now I do not think that there are above five or six, if so many, in consequence of the substitution of the man-engine.

3741. Then you attribute that change entirely to the substitution of the man-engine for the ladder ?—Yes, entirely. I ascribe that diminution of heart and lung disease to that cause.

3742. Have you any cases of consumption, not heart disease, at the present time ?—Yes, there are two cases, and then there is a case of miners' consumption; that man could attend to-morrow.

3743. Will you explain what miners' consumption is ?—Some people are of opinion that a line ought to be drawn between miners' consumption or between bronchitis and the consumption arising from tubercles in the lungs.

3744. What is your opinion upon that point ?—The majority of my cases are decidedly arising from tubercles of the lungs, but I term my other cases bronchitis, so that it is really nearly the same thing after all.

3745. Do you think that there was any cause where the man was working to create the bronchial affection? —Yes ; I think that the various things which I have mentioned are quite as likely to cause the one as the other.

3746. The poor air ?—The poor air.

3747. The dust ? — The dust and the climbing. Miners are also very incautious about drinking water, and washing in cold water. They are very fond of doing that, and can hardly be restrained when they are in a state of heat.

3748. Where do they wash ? Is it above or below ground ?—There is sometimes water turned off in a level for some purpose. A miner in a violent perspiration, when quite in a nude state, will plunge himself almost into this water.

3749. Is there any provision when they come to the surface for washing with warm water ?—There is at Par Consols.

3750. And you think that is very desirable ?—I do.

3751. Do you think that the bronchial affections arise, not only from these other three causes, but also from catching cold ?—Yes.

3752. Either on coming to the surface or from standing in draughts below ?—Yes. Last year we had in one portion of St. Blazey parish nearly 200 cases of typhoid fever; or as it is now, I think, called, intestinal fever ; and it is very desirable that some means should be adopted for having houses of accommodation. The cottages are built without any water-closets, or any accommodation whatever, and the consequence is that all the secretions are thrown about, and there is no doubt that they propagate fever to a most serious extent. Whether there could be anything done in that respect is a question. A miner is very fond of building a house, but he never builds the necessary accommodations with it.

3753. In front of the houses and about the houses there is not sufficient cleanliness observed ?—There is not.

3754. Does this produce fever or does it in your opinion have any tendency to produce the miner's disease ?—It has no tendency to produce the miner's disease, but I mean to say that when fever does arise in a district it is propagated by reason of the want of this proper accommodation.

3755. By the want of proper sanitary measures ? —Yes.

3756. That affects the general health ?—Yes.

3757. Does not it become the duty of the parochial authorities, or other parties, to see that the ground about the dwelling is properly clean ?—I do not know, very little has ever been done, we have had boards of health, but they have all died away, and at the present moment I do not think that we have one either in St. Blazey or in Tywardreath.

3758–9. Would it affect the health of a miner going down if his residence is in an unhealthy state ? would it render him more liable to take the miner's disease ?—No, I should say not.

3760. Then the state of his dwelling would not make any difference in that respect ?—Supposing a man is in the early stage of consumption, it would be very desirable that he should be in a well-aired room, instead of that the probability is that it is quite otherwise, they always stuff up the chimneys, and perhaps several persons are sleeping in the room.

3761. Then in the case of a person in the incipient stage of consumption it would aggravate his disease ? —Yes, in fact in the incipient stage of consumption everything is against the miner, very frequently he cannot obtain proper food. The parishes are very willing to listen to any recommendation, but they have so many claims upon them that if a miner has not been economical and he has to come to the parish, of course he must fare badly.

3762. Have you ever recommended miners who were your patients to get better food ?—Yes.

3763. Supposing a miner not to be able to provide for himself, would it be your duty to give notice of that to the parish ?—I am a parish officer as well, and I have the power of recommending food.

3764. Do you find that your recommendations are complied with ?—Yes, they are complied with, but still it would be very desirable if any means could be adopted by which a miner in the early stage of consumption could be removed somewhere where he could really have the proper quantity of food ; because, supposing that we order three pounds of meat a-week, the probability is that some of that food will go to the support of the family, and that the miner would not reap the entire benefit of it.

3765. We have had it in evidence, that though

St. Austell.

Mr. W. W. Tayler.

21 April 1862.

often given gratuitously, yet, in some mines, a warm basin of soup was provided on the men coming up; would that be conducive to health, and do you think that the miners would take advantage of it?—Some miners might, but I think that the great object would be to get home.

3766. (*Mr. Kendall.*) You have stated that you have about 350 men under your care?—Yes.

3767. And that out of those 350 men you have now two cases of consumption. Have you traced those two cases at all?—One case is hereditary disease, the brother died of consumption a very few months ago, and the mother died of consumption a few years ago.

3768. Have you seen the young man from his youth up?—Yes.

3769. Was he always delicate?—No, I could not say that he was.

3770. Did he attribute his illness at all to the working in bad air?—No, he came to me with the usual symptoms of consumption, and I advised him to give up working; but, as is the case in 99 cases out of 100, he got a little better and he resumed his labour, and he has not been ill, I suppose, above eight months altogether; I do not think that he will live another month, his brother died in precisely the same way. That is what I call acute consumption.

3771. But you do not attribute that to bad ventilation?—I do not.

3772. Have you traced the other case of the two?—I cannot say much about the other case, because the man has been at Cuba, and his constitution was severely injured there.

3773. Then he was a weak man before he came to work at a mine?—Before he came back to work.

3774. Did he work in the deep levels, or not?—He worked at Par Consols.

3775. But you are not aware whether he worked in deep levels or not?—No.

3776. With regard to the dust, you spoke very positively; you said that you had not only seen it but had smelt it?—Yes; that is my decided impression.

3777. From the breath?—Yes.

3778. More than once?—More than once.

3779. Have you ever had more than one complaint about the injury which a man has received from the dust?—They do not consider that they receive so much injury, but they consider that they do inhale dust.

3780. But do you consider that injury arises from their inhaling that dust?—I think so, partly.

3781. With respect to the miner's food—you know what their wages are—are the average gainings of the tut-work men and the tribute men such as to enable them to buy the food necessary for their hard work?—Yes; they have the means to buy sufficient food for their hard work.

3782. But you fancy, from your experience, that they do not eat animal food enough?—They do not.

3783. They have too much liking for the pasty?—Yes.

3784. Do you know much of the agricultural labourers as well as of the mining population?—I do not.

3785. You have not medical intercourse with them?—No; but I know that the men engaged in the railway consumed about three times as much animal food as the miners.

3786. I suppose that a navvy eats about six times as much as you could eat?—I do not know; I consume a good deal.

3787. Are you aware that a navvy will eat as much as three pounds of meat a day?—Yes; I am aware that they eat a good deal.

3788. Are you, or not, much mixed up with agricultural labourers?—No.

3789. Then you can hardly enter into the comparative diet between the agricultural labourer and the miner?—No; I do not know that I am competent to give an opinion upon that point; but I consider that the miner does not eat so much animal food as he ought to do.

3790. He takes his pasty underground, and it is not a healthy food in your opinion?—It is not a healthy food, and the quantity of meat in it is very small.

3791. But when he comes home in the evening he has his grand meal?—That is his principal meal.

3792. And then he indulges in fried potatoes and bacon?—Yes.

3793. Does he consume much fried potatoes and bacon?—Yes, an immense quantity; he is very fond of fried potatoes.

3794. The potatoes are boiled first of all, are they not?—Yes.

3795. And are then fried in fat?—Yes.

3796. And they eat them with bacon?—Yes.

3797. Is that a wholesome food or not?—I think it is wholesome and nutritious; it seems to agree with them very well. Potatoes are considered very nutritious.

3798. I understand from you that in your experience you think that much more disease arises from climbing than from badly ventilated ends?—Yes, I think so.

3799. In the Par Consols and the Fowey Consols, and in very deep mines, have you heard the men complain much of working in bad air?—No, I cannot say that I have.

3800. Are you led to suppose that without complaining they do work in bad air?—I have never been down.

3801. But do you suppose that they do work in bad air?—I cannot say that they do; the majority of the miners that I have spoken to upon the subject say that it is much better than in other mines.

3802. Do you think that if a miner worked in bad air he would be afraid to say so to you?—Certainly not; he would tell me so if he did work in bad air.

3803. Is the miner an independent man or not?—He is an independent man.

3804. He would not be afraid to tell you that he worked in bad air if he did so?—Certainly not.

3805. He would enter fully into the whole matter with you?—Yes.

3806. And as a general thing you have not heard the miners complain of working in bad air?—No; I have heard miners say that the Fowey Consols are better ventilated than other mines to which they have alluded in the west.

3807. You have referred to the cottages, and you say that there is not drainage enough?—I mean that there is not a proper house of accommodation.

3808. There is no privy?—There is no privy, that is all. I do not mean to say that every house is without one, but I think that the majority are.

3809. There is a great lack?—Yes.

3810. And a great lack of pure air in consequence?—No, I did not mean it in that light; I meant that when a fever arises in a district it is propagated by the filth which is accumulated. Supposing that a case of fever happened next door to the heap of filth, the probability is that that heap of filth would cause the fever to spread.

3811. Take the ventilation of the mines *per se* on one side, and take on the other side the act of climbing, the want of privies at home, the fact of the men sometimes having bad changing houses, and being exposed to cold and other want of accommodation, and perhaps in some cases not having quite food enough, which do you think is the most injurious to the miners, the ventilation or the other matters?—The climbing, I think, is the most injurious.

3812. Do you think that the illness which arises from imperfect ventilation is a small item as compared with the others, as far as you know and have heard?—Yes, as far as my experience goes, because there have not been great complaints made about ventilation. There may have been complaints, but not great complaints.

3813. I want to draw two lines: I take ventilation

as one, and I take as the other the climbing, the want of proper changing houses when the men come above, the want of care on their own part, and the want of privies and free air at home—which do you think does most damage to the miners?—The climbing and the other things which you have connected with it, decidedly.

3814. (*Mr. Davey.*) You say that there is an improvement in the miners' condition to your knowledge since you have been in practice?—Yes.

3815. Do you attribute that entirely to the man-engine, or to the improvement in ventilation?—Very great changes often take place in mines which I am not capable of explaining, but which a miner could explain very well. The mine itself, from various causes, various openings, and so on, may have greatly improved. None but a miner could exactly explain that.

3816. Did you formerly get any complaints of ventilation?—I think that years ago there have been complaints made respecting ventilation, but there are very few now.

3817. Do you consider that if a man climbed a ladder cautiously as any person might do, without racing, he would feel any effects from it?—They all complain if they have many ladders to climb.

3818. We have heard some witnesses say that the men race from the bottom to see which can get up first?—Yes, they are very fond of doing so.

3819. Do you not think that by that act of indiscretion they injure themselves more than they would otherwise do?—Undoubtedly, but even supposing that they did not race, and climbed the ladder very cautiously, if any man had the slightest indications of heart disease or lung disease, there is no doubt that the climbing would be very apt to bring that disease forward.

3820. Does the dust which you speak of go under any kind of decomposition in the stomach, so that you can smell it?—I do not know.

3821. Is it a rare instance that you smell it?—I have noticed it, I do not think it so very rare. I think that the breath of a miner has a very copperish smell very frequently.

3822. Those people who complain of the dust are only isolated cases?—Yes, it is not a general case.

3823. Do you not consider that the miners generally when they get home eat more broth than they do the other food which you speak of?—There is a great variety, there are the potatoes, and there is broth, and there is some meat; it is a miscellaneous meal.

3824. Potatoes having been comparatively dear, they have substituted other things?—Yes, but the miners grow a great many of their own potatoes; the miners employ their time after their hours of work in growing potatoes.

3825. Those people who grow potatoes generally have a pig also, have they not?—Yes, the great majority keep pigs.

3826. Therefore they would have a larger proportion of animal food?—It greatly depends upon whether the miner is provident or improvident; the provident miner keeps a pig and does tolerably well, but the improvident man who expends a great deal of money in drink and so on, cannot do so.

3827. (*Mr. St. Aubyn.*) You say that you have had very few complaints of the ventilation?—I have had very few.

3828. How many mines have you been engaged in?—Only these three mines, except when I was surgeon to an iron mine. I allude to the Par Consols, the Fowey Consols, and the West Fowey Consols; my experience is quite limited to those mines.

3829. You do not speak of the state of ventilation in other mines except those three?—No.

3830. The whole of your information, I presume, refers to the mines with which you are connected?—Entirely, I have had no experience in any other mines.

3831. We have had very conflicting evidence with regard to the dust; I think that you mentioned that as one of the causes of complaints among the miners?—I think so.

3832. A medical gentleman on Saturday told us that he had never in his life heard of anybody being affected in any way by dust. Are you aware whether the injurious character of the dust is in consequence of the nature of the lode?—Yes, no doubt it is.

3833. Is a mundicy lode likely to be more injurious than when they are driving through the simple stratum?—Yes, it is from some fine particles of mundic or copper; mundic, I believe, contains arsenic to a certain extent.

3834. When you spoke of the smelling of copper from a miner's breath, did you mean that it arose entirely from the dust, in your opinion?—Yes.

3835. And therefore, to produce that smell, the miner must have inhaled a quantity of dust which must afterwards have decomposed in the stomach?—I suppose so.

3836. You say that you do not consider that the state of the miners' dwellings has any influence on the disease which they are likely to contract in the mines?—No.

3837. But will not a bad state of drainage lower a man's condition?—As a general rule it would be considered so, but I do not think that that is so, as regards the miners, because some have been very healthy although residing in most dirty localities.

3838. Generally speaking, not only speaking of miners but of other people, the living in a bad atmosphere will lower a man's condition, will it not?—Yes, undoubtedly.

3839. Will not it predispose him and render him more liable to contract other diseases?—As a general rule it will.

3840. And therefore, as a consequence, he would be more likely to be affected by any bad influences with which he might meet underground by the bad state of the dwellings above?—I wish to correct an impression, which I see you have, with regard to the dwellings of the miners; I only allude to very few which are in this bad state. I suppose that you would find no cottages neater or cleaner than a miner's cottage, as a general rule, but I speak of some which are badly drained.

3841. I ask you with reference to those?—I should say that it is injurious; it is considered to be so; but to what extent I cannot say. I do not think that those men who live in dirty localities appear to be worse than those who live in very airy and clean houses.

3842. Your experience does not tell you that those who live in badly drained houses suffer more from disease than those who do not?—No; except an epidemic, like a fever, breaks out, and then the consequences of living in those dirty houses are seen.

3843. Have you been much underground?—Never.

3844. (*Mr. F. Egerton.*) I understood you to say, that you thought that the health of the miners had much improved during the last few years?—Very greatly.

3845. You attribute that, I think, to the use of the man-engine?—Principally to the use of the man-engine.

3846. Do you know at all whether the condition of the mines generally, in regard to ventilation, has improved in the last few years?—From conversations which I have had with miners, I am informed that from some change underground, which I am not capable exactly of explaining, purer air has in some way or other entered the mine itself; a change has taken place underground, I presume; it is not so cold and damp in places.

3847. What is the length of your experience in this district amongst the miners?—Twenty-four years.

3848. Have there been a considerable number of man-engines erected in this district?—Only two that I am aware of.

3849. Then your observation, I suppose, only applies to the condition of the miners who have used those engines?—Entirely.

3850. (*Mr. A. Bruce.*) You have stated that

ST. AUSTELL.

Mr. W. W. Tayler.

21 April 1862.

among 350 miners whom you attend, there are only two decided cases of consumption?—Yes.

3851. I presume, after the definition which you have given, you mean tubercular consumption?—Tubercular consumption.

3852. But taking it in the wider meaning ordinarily attached to the miner's disease, will you state how many patients you have suffering from the symptoms of the miners' disease?—Not any at Par or Fowey Consols mines; but there is one case of a miner which I am attending, on the parish account—only one—he did not work at the Par or at the Fowey Consols mine.

3853. How many patients are you attending at this moment at the mines?—You mean adults?

3854. Yes?—I do not think that there are above four or five.

3855. Is that an unusual state of health, or the ordinary state of health?—I think that they are very healthy, except when some endemic or epidemic is raging.

3856. Do you believe that the average of their lives is as long as that of agricultural labourers?—Certainly not.

3857. Then how is it that you consider that they are healthy?—There is a great deal of hereditary disease.

3858. Do you consider that a general average of health is consistent with short life?—It would not appear so. Hereditary disease exists to a very great extent in Cornwall, and consequently they die younger; and they are not ill very long. Most cases of consumption which I have are what I term acute, where the patient goes off in a few months.

3859. There are very few cases of acute consumption, and one out of the two which you have appeared to have been incurred at a distance from Cornwall. I am now speaking of the average state of health, and what I ask you is, to explain to us what you mean by the admission on one side, that the average of the life of miners is short, and by the statement on the other, that their general health is good?—Their general health is good, certainly.

3860. And their average of life is short?—And their average of life is short. It is an apparent contradiction, but it is so.

3861. These men are slow to complain, are they not, before disease is very decidedly developed?—I think that they are.

3862. Do you think that that possibly may be one explanation of the apparent contradiction?—It probably is.

3863. You have stated that in your belief not only the larger, but by far the largest portion, as I understood you, of cases of ill-health arises from causes other than bad ventilation?—Yes.

3864. You judge of the sufficiency of the ventilation not from your own experience, but from the general statement of the workmen?—Yes.

3865. Have you ever been underground?—Never.

3866. Have you ever inquired whether, in talking of good and bad ventilation, the workmen were using positive terms or merely relative terms?—I think positive terms.

3867. You believe that very few of the workmen in these mines are working in air where the circulation is languid?—I believe very few; but I have not had an opportunity of obtaining much decided information.

3868. When you attend a patient I presume that you usually inquire as to the causes of his ill-health?—One of the first questions which we ask is as to the air, whether there has been much gunpowder smoke. The purity of the air is one of the first questions which naturally arises.

3869. What has been the nature of the answers of your patients with respect to the air?—Generally satisfactory, as far as my memory goes, of late years.

3870. Have you of late years had any cases arising in your opinion from a defective state of ventilation?—I cannot call to my mind any decided case.

3871. You have spoken of gunpowder, and I presume that to gunpowder I may add the smoke of candles?—I do not think that the smoke of candles is injurious.

3872. Would not the smoke of candles be injurious in an air otherwise somewhat close?—They do not use many candles, I believe, underground; of course it would exhaust the air.

3873. You are aware, I presume, that even in the best managed mines it is impossible that the ventilation should be equally good everywhere?—I am aware of that.

3874. You are aware that where a man is driving a close end it is rare that the air there is as good as it is in the main levels?—Yes, I am aware of that.

3875. Do you not think that the smoke of candles in the close ends is an aggravation of the want of air?—I suppose that it might be in a slight degree; but I have never been underground, and do not know how many candles they do burn, but very few, I believe.

3876. They work by the light of candles?—They work by the light of candles, but, I believe, very few.

3877. In a mine otherwise dark?—They only use candles just in the part where they are working. I do not think that many candles are used underground In one small level which you describe I do not think that there would be above two candles.

3878. Have you ever inquired into the ill effects arising from hastening into close ends before the effects of the explosion of powder have passed away?—No, I cannot say that I have.

3879. You have stated that in your opinion working in places unusually hot does not affect the health?—I think that it does not affect the health to the extent that is imagined, it may affect the health in some delicate constitutions.

3880. Will you be good enough to assume entire ignorance on the part of the Commission, as to the question whether it does or does not affect the health of the miners, and to state positively in your opinion how far it does affect their health?—The miners who have worked underground the longest, and have worked in deep places and in hot places, do not complain; they do not think that they suffer. There is a man who is coming here to-day who has had very great experience; he has not only worked himself, but his sons have worked; he is 57, and he does not consider that working in a hot place is at all injurious.

3881. A miner of 57 is rather an exceptional person?—Undoubtedly.

3882. Therefore that man must have had a wonderful constitution?—He has been a cautious man, he has lived well.

3883. But if the age is unusual his good health must arise from other causes than mere caution on his part?—I think that a great deal depends upon caution. There is another man coming who is 66, who has also worked in hot places.

3884. As a class the Cornish miners are a temperate race of men, are they not?—The majority are undoubtedly, but then a great many are very intemperate, and those are the men who suffer most from working in hot levels and otherwise.

3885. Do you think that a man can work in a great temperature with all the consequent perspiration, and then move into far colder air without certain risks?—There is a risk.

3886. Do you not think that work carried on in a place of great heat must exhaust the frame?—It is calculated to do so.

3887. And in a state of exhaustion is not the frame much more susceptible of illness from other causes?—Yes.

3888. You have stated that although you have from time to time, as I understood you, many cases of heart disease, they rarely terminate in a fatal manner suddenly?—Rarely suddenly.

3889. What usually is the immediate cause of the death of a person who is suffering from heart disease? They frequently become dropsical, there is dropsy of

the whole system ; one of the first symptoms is that the legs begin to swell.

3890. Then they would be stated to have died of dropsy ?—No, I should return the case as having died of heart disease, and in the death certificate it would be stated as "dropsical" as well. Supposing that a man died of heart disease and had disease as well, both would be stated, one as the immediate cause, and the other as the proximate cause.

3891. When does the health of miners begin to fail obviously ?—I think after 40.

3892. Not sooner ?—Not sooner, as far as my experience goes.

3893. Do you think that the majority of miners work long after 40 ?—No, I should think not the majority certainly ; not long after 40.

3894. Taking 200 miners as the number working in a mine, how many of them should you think would be working after the age of 40 ?—I am not capable of answering that question without referring.

3895. I gather that you have stated that in your opinion miners might lay out their money more wisely than they do in providing themselves with food ?—Yes.

3896. You say that they would not eat so much as a railway labourer ?—No.

3897. Do you think that they work as hard ?—No; that has been proved ; they are not capable of doing the same amount of work in so many hours as the railway labourer.

3898. Why should they not be able to work as hard as a railway labourer ?—Because I think that a railway labourer consumes more animal food.

3899. The labour of the miner is very exhausting, is it not ?—No, not so very severe. In some respects I understand that it is not such very hard work.

3900. As a class, do they not perspire a great deal ? —That is in the hot levels.

3901. Is not the act of climbing itself one which leads to a great deal of perspiration ?—Of course, if they climb fast, which they will do.

3902. And may not the same be said of driving the borer ?—I suppose that that is laborious.

3903. And sinking shafts ?—I do not think that their work is so very laborious.

3904. Did you ever stand at the mouth of a shaft and see the workmen return from their work ?—No.

3905. You are unable to say whether or not they usually return from their work streaming with perspiration ?—I am unable.

3906. If you have satisfied yourself that the miners' work does lead to great perspiration, should you not think that they require a good deal of food to supply the exhaustion ?—Undoubtedly.

3907. Do you think that one reason why they consume less than a railway labourer may not be that their appetite is affected by the nature of the work which they perform ?—I think that there is something in that ; I think that it may be partly ascribed to that cause.

3908. Do you think that there may be a good deal in that ?—Not a good deal, but I think that that is one cause of it ; they complain that their appetite is not good ; they cannot eat underground.

3909. Have you ever heard a man complain that his appetite was not good before he came into your hands as a patient ?—Yes.

3910. To what do you attribute that want of appetite ?—There are a great many causes ; but one cause, perhaps, would be that certainly working underground to some constitutions is injurious, particularly to the agricultural labourer who has abandoned agriculture for mining.

3911. But it is not so injurious in your opinion as to bring many into the doctor's hands ?—That is my opinion.

3912. (*Mr. Holland.*) Is your knowledge of miners confined to those working at the Fowey and Par Consols ?—Almost entirely now. Some years ago I was surgeon to an iron mine.

3913. You cannot tell us whether your miners are much different from other miners in health ?—No, I should imagine that on the average they are pretty much the same. I believe that it is understood that granite mines are more injurious to the constitution than what are termed killas mines.

3914. Why ?—I only go by what the miners say, that the air is more cold and damp in the granite mines than in the killas mines.

3915. Do you mean by "cold and damp" that they have a great deal of cold damp in the mine ; that they cannot keep themselves warm, or that the air simply is cold ?—I suppose it is the air, but that is a question which I am not capable of answering positively.

3916. You have said that you have two cases of consumption out of about 350 men working underground ?—Yes.

3917. What cases of miners' consumption would there be altogether ; bronchitis, emphysema, and so on ; I mean what is popularly called consumption ? —It so happens that at the present time there is only one other case, but that is very unusual.

3918. You said that five or six men are now receiving pay for lung and heart disease ?—Yes, but they are not all attended by me.

3919. Those are not out of the 350 ?—No, that is out of the whole mass.

3920. Do you mean that there is only one per cent. of the whole number now ill from heart disease ? —It so happens at the present time.

3921. Is that usual ?—No, it is not usual.

3922. What is the usual proportion ? did you ever know 20 or 30 ?—No, never.

3923. Is there no such thing as one-third of the men, or anything like it, being ill of lung disease and heart disease ?—Never in these mines.

3924. Nothing like it ?—Nothing like it.

3925. I think you told us that a miner when above 40 was considered an old man ?—He is not considered exactly an old man, but it is soon after that period that the health of many begins to fail.

3926. We were told on Saturday that a miner at 40 was as old in constitution as another man at 50 ? —I should think that he was undoubtedly so, taking the average.

3927. How do you account for the fact ? what disease is there which shortens a man's life so much as to make the difference of ten years ?—There is no other disease but consumption in all its varied forms.

3928. Is it not possible that there are a considerable number of cases of illness among these men which do not come under your care ?—No, not among the miners in my district.

3929. Is it not common for men to be ill a long time before they come under your care ?—No, I do not think so. It is a very curious fact that just at this time there is very little sickness.

3930. I speak of generally ?—Generally ; of course, we have more cases of consumption and heart disease than there are now. What there were twelve months ago I cannot tell without referring.

3931. They do not die suddenly, do they ?—No.

3932. And they do die ?—They do die. There are two cases of heart disease at the present time, and those three cases of consumption, making five.

3933. But that is very much less than the average of the population ?—It is so at the present time ; but it may be very different twelve months hence, or it might have been very different twelve months ago.

3934. In your pamphlet published nearly 12 years ago, it is stated that out of a population of 6,400, 230 died in two years ; that is at the rate of 19 per 1,000 per annum ?—Yes.

3935. And of those deaths 39 were from small-pox ? —Yes.

3936. Omitting those, there would be only 15 per 1,000 per annum ?—Yes.

3937. That indicates a very healthy district for St. Blazey, does it not ; 15 in a thousand is a low death rate ?—Yes.

3938. You also state that at that time 64 of these deaths were from consumption ?—Yes.

ST. AUSTELL.

Mr. W. W. Tayler.

21 April 1862.

3939. Is that anything like the case at present, that a quarter of the deaths are from consumption ?—No; but some of those deaths from consumption were infants, and many infants die now. I think that two or three died in the last month or two.

3940. A while ago you said that the miners' consumption was to a large extent hereditary ?—I think so.

3941. Do the women suffer from consumption as much as the men ?—No.

3942. Not nearly ?—Not nearly.

3943. Do they suffer half as much ?—Not half as much.

3944. But, supposing that it is hereditary, would they not suffer as much ?—No; because supposing that the disease is lurking in the system, it is developed much more quickly in a miner than it would be in a woman who is leading a quiet life.

3945. But do you not know that in the general population of England women suffer much more from consumption than men?—Yes; but it is not so in Cornwall.

3946. But in the mining population the women suffer much less ?—Yes. I do not say that it is entirely from hereditary disease.

3947. Is it not likely that the difference between the liability of males and females to consumption in a mining district is not from the disease being hereditary ?—Yes. Supposing that a person had the seeds of consumption in the system, it would, of course, be more likely to be developed by working underground than by working as an agricultural labourer, or at any other employment.

3948. The difference of employment of miners and other males of England makes the difference between the respective death rates from consumption ?—Yes.

3949. (*Mr. Kendall.*) You have stated, as I understood you, that the average life of miners is short, and that their average health is good ?—Yes; that is a contradiction.

3950. But, as I understand, you state this with the exception that there are many cases of hereditary disease ?—Yes.

3951. How do you account for that hereditary disease ?—Very frequently it is in this way: that a miner, when in the last stage of consumption, may beget three or four children, and the probability is that the majority of those children (in fact, I think, that by a good deal of research you could prove it) would be consumptive.

3952. In olden time was much less care taken than is taken now, and did men in consequence become consumptive much more frequently than they do now ? Was there much care as to the dries and the mode of ascent, and so on, in your experience ?—I cannot say much one way or the other.

3953. Were there more cases of consumption in olden time than now ?—Undoubtedly; I think that the men are more careful of themselves.

3954. And that the mode of ascent is better ?—Of course the mode of ascent is better. I lay great stress upon the man-engine; I think that that is the salvation of the men.

3955. As regards the work of a navvy and of a miner, do you think that the agricultural labourer, who is in the open air, could at all compete with the navvy in work ?—I do not know; I am not capable of giving an opinion upon that point. I know from conversing with miners, that they were astonished at the great amount which the navvy did, and that they could not do so much work in the same amount of time.

3956. Do you think that if you put the navvies underground they could do as much work as miners ?—No, perhaps not; it is a different sort of work.

3957. Does the agriculturist eat at all like the navvy ?—I cannot say; I have never seen; I know very little of the agricultural labourer. I imagine that the navvy was enabled to perform so much more work because he consumed a great deal more animal food, and was enabled to digest it.

3958. (*Mr. Holland.*) And he was also able to use up that animal food by breathing well ?—Yes.

3959. Is it not understood in physiology that a man's force depends a great deal upon his breathing power ?—Yes.

3960. The amount of food which he can breath up ?—Yes.

3961. Therefore if a man were to eat more food than he could breathe he would get no strength by it; you have not considered that point, probably ?—I have not.

3962. (*Chairman.*) At what age do you consider that the miner's disease generally developes itself ?—I think soon after 40, except in cases of hereditary disease.

3963. You have stated that many of the miners beget children with the hereditary disease; does not the disease of a miner's son develop itself till he is nearly 40 ?—In those cases I think that it is developed very early. In those cases, of what we term acute consumption, where the patient dies very rapidly, it is hereditary disease.

3964. But it does not develop itself until the man works in the mine ?—No; very frequently not until after the age of puberty.

3965. Do you see that in the children dying off ?—Yes, frequently.

3966. Then a miner working, whose father died of consumption, is likely to go off sooner with the same disease than one whose father has been healthy ?—Yes, undoubtedly.

3967. Have both the mines of which you have spoken man-engines ?—Yes.

3968. Have you had any accident arising from the man-engine ?—Never.

3969. Have you had any cases during the last few years from accidents of any sort ?—Yes, we have had several; we are always having accidents.

3970. What do they arise from ?—From blasting underground.

3971. From any other cause ?—Sometimes by ground giving way and crushing a man at once.

3972. (*Mr. Kendall.*) Though you only attend these two mines, yet these two mines within your recollection have proved the largest mines in the county of Cornwall, have they not ?—Yes.

3973. They employ more men than the others ?—I think so; I do not know of any mine which has employed a greater number.

3974. (*Chairman.*) But you only attend about 350 ?—Yes, and Dr. Pace attends about 500 or 600; but the average number employed for many years has been about 1,000 or 1,100, and sometimes as many as 1,200.

3975. Unless they come to you as patients I suppose you never examine them ?—I do not.

3976. Do you think that any of those 350 men are now suffering from incipient miners' disease ?—There is one man whom I consider so, and I have advised him to give up working, but he will not do so. He is now taking cod liver oil.

3977. Have you any other cases under treatment of men who are still working in the mine ?—That is the only case, I think, of any consequence. Of course there are some who have little coughs and colds; I do not suppose that out of these 350 every one is well, there may be some trivial cases, but what I have mentioned are the only cases of any consequence.

3978. And you think that those trivial cases are not likely to lead to serious results ?—I do not think that they are.

3979. (*Mr. A. Bruce.*) What is the entire number of men engaged in these two mines who have a right to medical attendance ?—I should think on a rough calculation from 1,100 to 1,200; about 1,100 now.

3980. How many of those are under your medical supervision ?—I suppose nearly 400.

3981. That includes miners and non-miners ?—Yes, everybody.

3982. Do you suppose that all those men come to

you as their regular medical adviser?—I have no doubt that they do.

3983. Do Cornish miners show what I have observed in other mines, namely, a tendency to avail themselves sometimes of the advice of what may be called irregular practitioners?—Yes, they are very fond of taking quack medicines.

3984. Do you suppose that any considerable portion of your miners may be taking quack medicines, or having recourse to other persons for whom they may have a fancy?—I am not aware. From inquiries there are no acute cases of disease at the present moment, I am pretty certain; there may be some chronic or stomach complaints, or various things. I wish to mention that what I have stated might convey an erroneous impression; it is not to be supposed that all the 350 or 500 are adults, because a great many of them are not aboye 13 or 14, or perhaps 12 years old, but they are all put down as miners; they go underground and are entered as such in the club.

3985. (*Mr. St. Aubyn.*) You stated that hereditary disease prevailed among the miners and their families to such an extent that their children were carried off in great numbers by it?—Yes, a good many are.

3986. Do you mean to convey to the Commissioners the impression that when a miner dies of consumption it is rather owing to hereditary causes than to the nature of his employment?—I think that in the majority of cases if the matter was sifted out it would be found to be the case.

3987. In other words, that if they had not been employed in the mines they would equally have died of hereditary consumption?—Yes, the majority; but then everything must have a beginning; the first case of consumption of course was not hereditary.

3988. (*Mr. A. Bruce.*) Then how do you explain the fact that women do not die of consumption?—I do not say that none do, but not in such numbers; there are some who die of consumption. Cornwall is a county where consumption prevails amongst all classes.

3989. Surely not to a great extent?—Yes; I suppose that there are few counties where there is more consumption than in Cornwall.

3990. (*Mr. St. Aubyn.*) In other words, your opinion is, that where a miner dies of consumption, it is not owing in the majority of cases to the nature of his employment so much as to hereditary causes?—Just so; I think that there is more consumption in Cornwall than in any other part of England. I am at this moment attending two cases of consumption in private practice.

3991. You say that in the majority of cases it would be rather owing to hereditary causes than to the nature of the employment?—That would, I should say, be a very slight majority.

3992. Would it be half?—The probability is that it would be half.

The witness withdrew.

Mr. John Pearce examined.

3993. (*Chairman.*) You reside at St. Austell?—Yes.

3994. I believe you have the medical charge of some of the mines in this neighbourhood?—Yes.

3995. What mines are you engaged in?—I have Polgooth, part of East Crivvis, part of Par Consols, West Fowey, Cornubia, Cuddra, Great Crivvis, East Polwear, West Polwear, West Par, Dougas, and Crow Hill. I have the entirety of these except East Crevvis, Par, West Fowey, and East Polwear.

3996. You have heard the evidence given by Dr. Tayler?—Yes.

3997. Will you have the goodness to state to the Commissioners the points upon which you do not concur with him?—I concur in most of Dr. Tayler's general statements, but there are some points as to which my experience varies from his.

3998. In the first place, do you agree with Dr. Tayler as to the general health of the miners, and their average longevity being low?—I do not think that the miners, taking them as a class, are so healthy as agricultural labourers.

3999. What do you say as to their average longevity?—That is low, but there are other causes besides disease that will, in some degree, account for that.

4000. Will you now be good enough to state the points upon which you do not agree with Dr. Tayler?—His examination has extended to so many questions that I cannot very well recall every point, but with reference to one part of his evidence, I may state that I never noticed any smell from the breath of miners working in copper mines, nor can I conceive how any smell could be produced, even if they inhaled the dust, because a chemical change would have first to be undergone, and the sulphur would have to be liberated from the copper. Even granting that they did swallow much dust, and I believe that they do swallow some, I think that before any smell could be produced by it, there would be a decomposition of the mineral take place, and if that were the case it would equally apply to the Fowey mines where free arsenic would be liberated, and we might have poison from arsenic, and that we never see. Therefore any injury that might be derived from dust would be rather from a mechanical cause, than from any chemical alteration being produced.

4001. What is the next point as to which you differ from Dr. Tayler?—Dr. Tayler was asked whether he had heard the miners complain of any symptons that were produced by working in bad air. I believe that our mines are, generally speaking, as well ventilated now as they can be, perhaps some more precautions might be taken; but it often happens that where the air is bad it is in an and where the men are driving to come to a shaft coming down to give them air, or they are putting up a rise, and very often I have heard the men say that their heads have become light and giddy, and that they have had a ringing in the ears which is produced by a bad supply of oxygenated blood to the head. Then again with regard to diseases of the heart, as far as my experience has gone, I have observed a great deal of enlargement of the heart, and that enlargement would necessarily be permanent, and there is hypertrophy of the heart induced by the extra action which the heart is called upon to perform when the men have been climbing from great depths, an increased pulsation of the heart is then caused and increased respiration, and hypertrophy, which is a thickening of the heart. Sometimes there is more functional derangement from which the miners may recover, as is the case with others. Another thing that has struck me forcibly is that miners have not suffered, if at all, more than an equal number of the population in any other class, from phthisis or tubercular consumption, of which there may be perhaps a slight average against the miners; but, as a general rule, I should say it was not so. The disease of the miners which is called consumption, in my opinion, is decidedly nothing more than bronchitis, having the general symptoms of tubercular disease, but those symptoms being very different in their stethoscopic character. I particularly agree with Dr. Tayler as to the state of the dwellings of the miners, that they have been the hot-bed of disease for any epidemic that may occur. I believe that the want of ventilation in their houses, and the want of cleanliness about their doors, have been a very fertile source of disease when any infectious epidemic has broken out. With regard to their being supplied with soup after they come from underground, my opinion is that giving persons food when the nervous system has been ex-

St. Austell.
Mr. J. Pearce.
21 April 1862.

hausted by climbing or from hard work, is not advisable, and I think it would be better for them to go home, and have their meals quietly. As to the difference in the health of agricultural labourers as compared with miners, I think that a great deal depends not only on their employment, but also on the management of their wives in their houses. I think that the wives of agricultural labourers are much more provident than the wives of miners, and I think as a rule, when I go into the different miners' dwellings, I can almost tell at once whether the wife has been a bal girl, or whether she has been taken from respectable service as a servant girl. With regard to the way in which miners are able to speak of the bad air in the mines, their practice is to notice their candle in burning, for where the air is very bad it will go out. As to their appetites, I believe that although the miners, as a class, smoke a great deal less now than they did formerly, yet I think that that may be one cause why their appetites are not so good as compared with an equal number of men who do not smoke. With regard to the navvies eating so much and doing so much more work, when they go to work, I do not believe that at first they could sustain the work so well as they can after a continuance of it. I think that the continuance of any kind of labour enures the system to that kind of labour which men may adopt. I also agree that although a miner would not be able to do the hard work that a navvie does, on the other hand the navvie could not work in the cramped places that the miner can, and that each is peculiar to his class. I do not think that you can draw a fair comparison between them. With reference to what is termed the miners' disease, and which I consider to be bronchitis, I think that the climbing up of ladders often carrying tools, and the increased action of the heart and respiration on coming to the surface in an exhausted state, and their sudden exposure to the cold, are also another source of their disease. They come up from different kinds of atmospheres, and the atmosphere varies in different kinds of mines, some being better ventilated than others ; and also the air in some close granite mines is much more damp and heavy than it is in killas mines. I might refer to Beam mine, where, some years since, nearly all the miners suffered from miners' consumption ; it is now abandoned.

4002. Where was that mine ?—It was in this neighbourhood. They suffered very badly, and I would account for that by the ventilation not being so well attended to there, as they had not so much necessity to drive out the smoke from the powder, there was very little blasting, and the ground being easy retained the damp to such an extent that the timber would often become loaded with fungous growths, and all the atmosphere would be dead and heavy. The men in those days were in the habit of drinking more in that district, and they would often go down half drunk, and sleep underground ; but the Beam mine was observed to be one fertile source of the peculiar disease called the miners' disease.

4003. (*Mr. Austin Bruce.*) How long ago was that ?—About 20 years since ; but many of the men lived there, and I suppose some even live now who have this miners' consumption ; we can see it for years before it takes such a hold of a man as to incapacitate him for working. A man may continue to work, although the disease has already begun to form in him. I notice that they were all old men in Beam mine at the age of 40 ; but I should not call all our miners old at 40. In Beam mine it was the case, they looked like old men ; in fact, in riding through the district, if you saw them, you would say, "that is a Beam man." I have also made this memorandum that the men very often rush into hot-air ends after blasting a hole with powder, they rush in too soon. I have been told that they are anxious to see the result of the blasting, and that hot air has immediately produced coughing ; and this disease, which is called miners' consumption, although it is not tubercular consumption, is just as certain in its results ; it has all the general symptoms of phthisis, and is as certainly fatal in its termination as is consumption I can compare Bucklers Charleston mine with Beam. It is an unusual thing to find miners' consumption formed in Bucklers Charleston mines ; it is not very deep, and it is very well ventilated. I speak of the former working. I do not attend there now, and all the mortality among the Charleston miners I consider is produced in the first place by accidents which are unavoidable in many instances, and one of the greatest sources of injury to the miners is their blasting with open powder, putting it into the holes in that state instead of in cases ; that is a frequent source of accident.

4004. (*Chairman.*) What do you mean by the word "open" ?—The miners will bore a hole and put the powder into that hole, without putting it into a case, and I think that no case of an accident from blasting has occurred where a proper tube has been used, and the powder has been put into the tube to be put into the hole ; it is for this reason that the men in putting in their powder very often leave grains of the powder adhering round the hole and round the mouth of it ; whereas, if it were put in in a case the powder would not be loose, and there would not be the same chance of fire getting to it as there is when it is put in in a naked state. I think also that it is not so liable to explode in the tamping, and another cause of accidental explosions is this, as I have often said to a miner, "You have been using the mallet again," instead of holding the bar in one hand and beating it with the hammer himself, when he would feel what resisting power there was ; one of the miners will hold the bar, and another miner take the hammer, and beat it with two hands as if they were boring. That is prohibited by the agents, but the miners frequently do it.

4005. (*Mr. Austin Bruce.*) That might lead to the ignition of the powder ?—Yes, by concussion, by more violently striking the tamping rod. Another cause of the low mortality is that the young men who go underground for some time come up very fast, racing one after the other to see who can come up the fastest ; and another thing that should be attended to is as to closing an old shaft. I have known men fall down into an old shaft which had been left open after it had been abandoned, and when they have been reworked again those old shafts have not been known, and they have been allowed to remain open. I, therefore, think that every shaft when it is abandoned should be hedged in so as to protect the public. It often happens, I believe, that the constitution of miners is impaired by a number of persons sleeping in the same room, because there is not sufficient air for them to breathe in their sleeping apartments. I think also that the changing of their clothes on the boilers is bad, and that the substitution of dries which are now properly constructed would be a very great benefit to them if carried as far as possible, and that their illnesses would be considerably lessened compared with what they are at present. Then with regard to the hot ends, after the miners have been working in them, I have heard them complain ; at the mines I have been engaged in I have not had many of them, but I have heard them complain of them, they became very pale ; but the hot air ends I do not believe always depend so much upon ventilation as on the chemical change that is going on in the contents of the lode, for the one there might be a remedy provided, but not for the other. Another cause of the low mortality among miners is the loss of life which results from the men going in too soon after a hole has misfired ; it sometimes happens that it misses, and they go in to see the cause why, and the powder in the hole then explodes, and they are injured in that way. I also think that it is a matter of importance that upon mines being abandoned the parties concerned should be compelled to give plans of them, so that if the adjacent ground is worked there should be no danger of holing into an abandoned mine, which was the case in this neigh-

bourhood some time ago when two or three lives were lost in consequence.

4006. Do you mean that there should be a registry kept of mines?—I mean some means by which, if, for example, half of this room had been worked, and I was in the other half which was about to be worked, we should be able to see how far the ends had gone on here.

4007. You mean that there should be a registry of mines?—Yes; another cause of the miners' disease, I think, is their coming out after the firing of a hole, and sitting down for some time before they go in again in the cold, and perhaps they touch a pipe, or eat a bit of cold pasty which they take with them underground, and during their work I do not think that cold pasty is an advisable thing, or that digestion and the exercise of the nervous power in working should both be going on at the same time. I think that if the miners, after blasting, were to go and turn a fan instead of sitting down and doing nothing, and if all those close ends were supplied with the means of sending in air, which they might easily work, they would probably clear away the smoke much more quickly, and obtain a better atmosphere from it. In my opinion the man-engines are the best things that have ever been introduced for the benefit of the miners, and for the reasons that I have already given, from the exhausted state in which I have seen the miners come up off the ladders, and the quiet way in which they appear to come up by the man-engine. I remember standing at a shaft at Fowey Consols, and I saw some men come up by the man-engine apparently as little fatigued as possible, whereas before, after coming up the ladders, I have seen the sides of their chest heaving, and the men were breathing as quickly as possible, but now you do not see that when the miners come up by the man-engine. At the same time I think if they could be induced to climb up more slowly it would be less injurious, or as an old doctor once said, if the miners spent half an hour more in coming up, and half an hour less in bed, they would have a benefit both ways. I think it would be desirable if some statistics were collected, which we cannot give you, showing the difference between the longevity of the tutwork men and the tribute men; I believe that one is longer lived than the other.

4008. (*Mr. Kendall.*) The men employed at tribute work being longer lived?—No; the tutwork men being longer lived, and my reason for saying so is that the tributor is down underground more hours than the tutwork man. I do not believe that the tutwork man works so hard as the tribute man, nor do I believe that the tributor's living is so certain and regular as the tutwork man's.

4009. The tribute man has more air to breathe, has he not?—As a rule I should say that he has.

4010. (*Chairman.*) Should you think that good living has something to do with the state of health of the miners?—Yes; but I should say that it is not so much that, as that what they have, I think, is better managed. The miners are a different class altogether from agricultural labourers. I have made a note that something might be done as to the wood which is used in some places, and which gets covered with fungous growths. I think that if the wood was prepared in some way it would not be so deleterious to the atmosphere.

4011. (*Mr. Kendall.*) Do you mean kyanized?—Yes; only in particular places where we should see that there was a tendency to fungous growths. I think that wooden air pipes are very bad for use in a damp state, for the wood absorbs a great deal of the air that has been driven into the mines. Then with regard to the miners' clubs I have often observed when mines have been abandoned that the men who have been permanently injured there have had no means of getting their club money after the mines have been abandoned; notwithstanding that the mines may have produced a large sum of money which has been placed in these clubs, it has been taken by the purser or the secretary, or otherwise disposed of, and I would suggest that the money when old mines are abandoned should go into some general fund, and be disposed of for the benefit of those who have been permanently injured.

4012. (*Mr. Austin Bruce.*) Are the clubs usually registered under Mr. Tidd Pratt's Act?—No, none of them, and when a man is injured his means of support are cut off in that way, and they have to find other resources, and very often I believe they want, whereas if there was a general fund for mines, when suspended or abandoned, for the men to pay into, I think that the miners would be very much benefited.

4013. (*Chairman.*) Have you ever been underground?—Yes.

4014. Have you been underground at any of the mines in which you superintend the health of the miners?—Yes, I have been down to a great depth.

4015. When a miner who suffers comes to you in a state of ill-health, do you ask him where he has been working, or at what description of work he has been employed?—Yes, very generally.

4016. If he says that he is suffering from working in poor air, do you inquire as to the nature of that poor air?—Yes. I say to him, "How long have you "been in poor air?" He answers and says, perhaps, "We are driving in an end with the object of getting "down a rise or putting one up." I do not think, as a rule, that they do work in bad air long together. As soon as they have finished any work in this bad air they come, and they seem to have the notion that they might have such a thing as an emetic to throw off the foul air; they say, "We have been working in "bad air, and we want some medicine to throw it "off."

4017. Have they ever complained to you of swallowing the dust in the mine?—Yes.

4018. Have you ever seen them spit?—Yes. I have seen them spitting up the powder smoke.

4019. Any other dust?—I do not remember that I ever saw them spit up any other. When they are laid up with illness we do not see it. I do not believe that any mechanical body remains in the mouth or throat.

4020. You have stated that wood is deleterious, do you know of any case where decayed wood has been deleterious to any patient of yours?—Yes. I speak now particularly of Beam mine; we found that the wood there was very commonly covered with wet fungus after being in there a short time from the damp heavy atmosphere.

4021. And not from the want of proper ventilation?—That mine was not so well ventilated as others, for this reason, that they did not feel the necessity for it as they had not so much powder used in blasting, and therefore not so much smoke.

4022. Is the principal object in trying to ventilate mines to get rid of the powder smoke?—That is one object, but it is not the principal one. All mines must be ventilated, and there must be a means of throwing in air, either mechanically or by arrangements. I believe that the ventilation of our mines is very much better now than it was formerly.

4023. Do you know of any other mine where wood has been deleterious?—Certainly not as a rule. I remember one case of a young man who suffered from ague, and he attributed it to holing into an old shaft where the wood was very much decayed, and he said that he noticed a smell from the old wood, and he attributed his attack of ague to that. I, of course, cannot say that such was the case, but that instance just occurs to me at the moment.

4024. When any patients come to you, saying that they have been suffering from working in poor air, do you report that to any person?—If I were to see a case the miner would not hesitate to tell me anything that he thought was not right, it is very unusual to hear any such statement made; but if any such statement was made to me, and I thought there was any truth in it, I should take the first opportunity of saying to one of the captains, "Such and such a place is found to be,"

so and so, "and if it could be altered it is very desir-
" able." There would be no difficulty in my making any such statement, nor should I hesitate to make any such statement.

4025. But are there cases where, in your opinion, poor air cannot be avoided ?—Yes, in cases where the men are putting up a rise to get air ; I think that in those cases there may be a difficulty.

4026. You have stated that you think that a miner working in poor air for some weeks would be likely to suffer in his health ?—Yes, he necessarily would suffer.

4027. How long do you think a miner could work in that kind of air without suffering ?—That depends upon the degree of impurity that there is. In some cases such rises are nearer to another rise than in other cases ; it depends upon circumstances, they judge of it by the way in which the candle burns ; if the candle will not burn unless it be turned down, or even then that it would go out, I should say that the air was very bad. If the candle burned steadily on its side, then it is considered that where a candle will burn a man can live.

4028. Is it your opinion that where a candle will go out when it is held upright, but will burn on its side, the air would be very bad ?—Yes.

4029. The air would be bad if the candle would only burn on its side ?—Yes.

4030. Therefore you would recommend any patient of yours not to return to that same kind of work ?—The work must be done, or they could not get the ventilation for further working. I think the agents do not keep the men at it ; if the men have been put up on a rise and they have got on with it, probably the men would not have to do that for months again, and they could not get the natural ventilation without.

4031. You would recommend a patient of yours not to go back to the same kind of work ?—Yes ; but they do not complain immediately of this ; they may come and complain of lightness in the head, but they do not complain of the miners' disease immediately.

4032. If a man came and complained of lightness in the head, should you then advise him not to go to the same description of work again ?—That would depend upon the extent of it ; he might be laid up for a day or two, or more, and then he would go to work again at the end of the week, and in a week or two the natural ventilation would take place.

4033. But suppose it did not take place for more than a month, would you in that case recommend your patient not to go back again ?—Under such circumstances, if he was so bad as not to be able to work he would be laid up, but if he could go to work he would probably go back to the same place. If I saw him suffering from tightness at the chest, I should say, "You must tell the captain," so and so. "I do not consider you fit to work there," that I have often done.

4034. Still you say that the work must be done, and if that man did not do it somebody else would do it ?—Yes.

4035. That is to say, if one man's health will not stand it another man must try ?—Yes ; but it is for so short a space of time.

4036. Are you able to speak from experience upon that ?—Yes ; I know something about these matters. I have been an adventurer as well as a medical man in the mines.

4037. How long has it taken to get through the work in your experience ?—That depends upon whether they sink from below, and that they would do if the air was very bad ; it depends also upon the character of the ground, whether it is very hard or not.

4038. May there not be occasions when it would take some time before they could complete the work and obtain the ventilation ?—Yes, it might be two or three weeks.

4039. During that time if one man suffered from the poor air, and was laid up, another man would have to take his place ?—Certainly.

4040. You stated, I think, that the disease from which miners most suffer is enlargement of the heart ? —Yes, hypertrophy, we do not generally find the heart so much dilated as thickened.

4041. How are you able to judge of that ?—By the stethoscope.

4042. Have you ever had any opportunity of judging from post-mortem examinations of one of these cases ?—Yes, I have seen them, but not particularly to trace hypertrophy of the heart ; it is so marked a case that we do not require to do it.

4043. Are you of opinion that that, generally speaking, is the commencement of the miners' disease ? —No ; I should not say so.

4044. What is the commencement of that which is called the miners' disease ; how does it show itself ? —I think it is caused by the foul air.

4045. How does it show itself ?—The first thing is that for many years before it has the effect of incapacitating a miner there is a shortness of breath, and a catching and hesitation. I have noticed that particularly in their speaking, they talk for some minutes, and then they breathe apparently with difficulty, that is the first thing that I notice in them, and I have often said, "I think it would be an advantage to you " if you could work on the surface for some time."

4046. At that time have you observed any cough ? —There is very little in the beginning.

4047. When you do observe it in a patient, do you advise him if possible to leave the work he is at ?—Yes. I advise him to do so. I should say, "You " must get on to some of the upper levels. You must " not climb so far, and you must get into good air."

4048. Although you appear to think that the air below is not poor, yet is it so good as, in your opinion, to be conducive to the miner's health ?—No ; and besides that, there are so many changes in those places to which they are exposed ; there are great draughts in some places, and in others the air is more confined, in some places it is cold, and in other places, it is much warmer, and then there is always a change on coming to the surface.

4049. That change of air and going into draughts in the mines at the commencement would be injurious, would it not ?—Yes, decidedly.

4050. If a man feels ill, does he, on all occasions, apply to the doctor ?—These men are very susceptible to cold, and if they get cold they get more cough, and then they come and complain of tightness in the chest.

4051. But many of the men may work on for some time without complaining ?—Yes, for many years. There was one poor fellow who has just died, and I knew him to have symptoms of the disease from which he died, 15 years ago.

4052. Was he then told that there was a chance of its terminating in the way it did ?—I had often said to him, "I will give you something to relieve you, " but yours is the miners' disease, and we cannot " alter that state of the chest."

4053. What was his reason for going on working after that ?—I suppose it would have been difficult for him to get anything else to do.

4054. He was compelled to work on for his livelihood ?—Yes.

4055. Does not it end in the formation of tubercles on the lungs ?—Decidedly not. I am positive upon that point.

4056. This peculiar disease does not end in tubercles ?—It is not tubercular disease, but it has all the general symptoms of phthisis, but it is a different thing from tuberculosis.

4057. Therefore it is more like bronchitis than tubercular disease ?—Yes, the stethoscopic symptoms are quite different.

4058. Will you be good enough to state to the Commissioners the difference between common consumption and the other disease, called miners' consumption ?—In a case of phthisis we have deposits

of solid bodies in the structure of the lungs, not in the air tubes, but between them. That is its first condition, and it goes on to produce ulceration in the cavity, that is phthisis, but this disease of the miners is, in my opinion, a low kind of inflammation which is set up at first in the air tubes, and which occasions a thickening of the parts from congestion, and then the vessels relieve themselves by copious expectoration, like all other diseases from impurity of the blood; all the other symptoms of phthisis go on just the same as if it was tabercular disease.

4059. You have stated that it was the opinion of an old medical man here that if a man took half an hour's less sleep and half an hour longer to come up it would be better for him?—Yes.

4060. But does not the time that the men take to go up and down depend upon themselves?—Yes, they may take what time they please to come up, and I never heard any fault found because they were not in their place of work at a certain time.

4061. But they would be complained of if they came up before a certain time, would they not?—Yes.

4062. Is it not natural that a man, after he has done a hard day's work, should like to get up to the surface as quick as he can, and go home?—I do not think that the men are anxious to get home. I have very often seen them chatting about the boiler house.

4063. Would not a man, after he has fired a shot, have to wait somewhere?—Yes.

4064. Might he not catch cold by waiting in a draught down below on the ladders?—Yes; and I have suggested that if he had a little wheel to turn in order to drive in air to his own end, instead of standing still, it would improve his atmosphere and do him good.

4065. Do they not generally contrive to fire a shot a short time before the time arrives to come up to the surface?—I understand that it is so.

4066. Therefore, when once a man has fired his shot he might leave the place, and, if so, he would only be ventilating that working for the man who succeeded him?—That is true, but they do not shoot their holes in the middle of their cores perhaps more than once.

4067. And on those occasions you would suggest that the man should work a fan in order to drive in air?—Yes.

4068. You have stated that the effect of the bad air is to make the men look old?—Yes; the blood is not renewed, and the parts are not so well supplied as when there is the necessary quantity of oxygen, they have to consume a greater amount of air to obtain the same results.

4069. Should you say that the miners do generally look old?—They have a pallor, and there is a peculiar appearance about them as a class, but they are very wiry men, and capable of enduring a great deal of fatigue, and they also appear to have a great deal of muscular power. I have seen them working under ground, and I have seen them hard at work boring, and I have been surprised to see the way in which they will go on for ten minutes beating the borer, without ceasing, calling not only the chest into play, but the muscles of the abdomen.

4070. That kind of labour must take a good deal out of them which ought to be replaced by good food?—Yes; but I do not think that the good food they want is food that would fatten them.

4071. But they want something to replace the loss they have sustained?—Yes.

4072. Did you not state that you considered a pasty a bad thing for them?—Yes, it is indigestible, and not only that, but I think that the men eating such indigestible food as cold pasty, and at the same time requiring their nervous power for muscular action in their work, they want that nervous power for digestion at the same time, and, therefore, instead of doing them good, I think it does them harm.

4073. It has been stated to the Commissioners in evidence that in former times it was not the habit to take the cold pasty down with them, but that since it has become the habit to take food down with them the miners have become more healthy?—Some time since I made this a leading point with the men. I believe that they used to smoke a great deal too much, and I said that if instead of smoking so much tobacco they were to take crib with them, which means a piece of bread, if they could not afford meat, it would do them more good, that they would be better if they did that instead of smoking so much.

4074. You think that if they took down with them some good wholesome food, and ate it in their intervals of rest, it would be advantageous to their health?—Perhaps to a limited degree, for I cannot consider that a man who is working hard should load his stomach with food.

4075. Light food would be more advantageous than heavy food?—Yes, to a limited degree.

4076. You have also stated that the men suffer from catching cold when they come up to the surface?—Yes; I think that when they came up before there were any man-engines they did so. I refer only to mines up which they climb on ladders when they come up heated, and have nothing about them but a loose flannel covering, and that only just on the shoulders; the sudden exposure to the atmosphere would render them more liable to bronchial disease.

4077. Then it would be very desirable, would it not, to have a changing house as near to the footway as possible?—Yes; but I think that the great thing that would obviate that state of perspiration would be some means to enable them to come up more easily. I believe that that is the great thing the miner wants; it is not necessary in very shallow mines.

4078. You have heard it stated that miners are apt to wash in cold water, and that they suffer from that?—I think that they very often get warm water to wash in, when they come to the surface.

4079. Do you not think that that is very desirable?—Yes, and they may have it if they like; there is plenty of hot water always running away from the hot air cistern. It is at the mouth of the shaft, and they may take it if they please, and my impression is that they very often do take water from there.

4080. But is it conveniently placed for them when they come up?—There is no difficulty in their taking their pan, and taking some water out of the hot air cistern.

4081. But would they not have to go in the cold air to fetch it?—No, they most frequently come up inside the shaft.

4082. Is the changing house generally near the engine shaft?—Yes, but it is not at all mines that they have a changing house. It is more generally adopted now than it was formerly; they used to change on the boilers.

4083. Do you think that is a good system?—No; there is plenty of dust there, and the steam is blowing out, and there is the danger too, although it very rarely occurs, of an explosion.

4084. Therefore it is desirable to have a changing house?—Yes.

4085. Do you think that the changing house should be the same as the drying house where there is a good deal of dust?—It would be the better course, but we must look in some degree to the building of these places. There is no question that it is far better for a man to breathe the clear atmosphere than where there is plenty of dust.

4086. Therefore it is essential to the man's health in some degree that there should be warm and convenient changing-houses?—Yes, I think that they are very likely to be a great benefit to the miners.

4087. Are there any men who have met with accidents now under your care?—Yes, several.

4088. What number of cases have you on your hands now?—I am now attending four men who have been injured by blasting.

4089. How were they injured?—By the sudden explosion of the powder in the hole.

4090. What is the nature of the injuries they have sustained?—They are generally about the face.

4091. Do the men sometimes lose their eyesight?—Very frequently.

4092. Will you be good enough to state how the accidents to which you have just referred have occurred?—They occurred in tamping. There was one case in which a man was looking into a hole on the naked powder. I do not know for what cause, but they often come to the hole before they put in their tamping and look down, and I have a notion that if there is a fraction of powder present, or, in fact, any powder containing sulphur, that free sulphur is thrown out, and that may be the means of carrying fire down to the naked powder. Hence, I have strongly suggested that the powder should be put in cases, and put into the holes in that way. In two of the other cases the accidents resulted from putting in what they call their first laying of tamping, and there they were using mallets, that is, one man was holding the bar, and another was beating it in. In the third case the accident also arose from putting in the tamping on the powder.

4093. In the latter cases the accidents arose from the men's own fault?—Two of them did, but in the other two cases it did not appear to be so, as the men were tamping in the ordinary way.

4094. Were these the first and only cases that have been brought under your notice?—No; I have had, I dare say, 40 or more cases; and I remember some time back, where the Charleston mines were being worked the last time, that they used to shut the cracks, and put in a very large quantity of powder, and most fearful accidents resulted from that practice. It could not be from tamping, but the men would look over their cracks with a candle and the powder would go off, I cannot say how, but I have there seen it; I recollect one case in which a man was brought up in a bag, he had been blown literally to pieces, his arms in one place, and his legs in another. But such fearful accidents do not occur where there is simple shooting in the ordinary way.

4095. Are there not strict rules and regulations laid down for the observance of the men?—The men are forbidden to go in after a hole has missed fire; they are forbidden to go in again during that spell, and they are told that if any accident occurs from their using a mallet, as I have just spoken of, they shall have no benefit from the club; but still they do it.

4096. Have any accidents come under your notice of late years?—We frequently have accidents when the ground falls away upon them.

4097. Do any accidents occur from falling away from the ladders?—Yes; I have known many cases of that kind.

4098. How have those accidents occurred?—Sometimes from a man thinking of one thing and doing another; perhaps he is speaking to another person, or there may be a defective bar.

4099. Are the bars of iron or of wood?—They are of both; some ladders are made entirely of iron staves, some have wood and iron; I have seen them made all of wood, but that is rare.

4100. When the miners fall from the ladders are they generally killed?—As a rule I should say no.

4101. What precautions are taken to see that the wood of which the staves are made does not get into a decayed state?—They are passing up and down every day, and the agents can observe it if it is

4102. Still they may break away?—Yes.

4103. Is it not desirable to have all iron staves?—I should say so myself.

4104. Do you know whether any accidents have occurred from a shaft being imperfectly protected, and from the footway being in one part of the shaft, and the woodwork between the two being broken away by any material that has fallen down?—I have never known an accident occur from that.

4105. (*Mr. Kendall.*) With regard to any injuries arising from the copper dust, do you think that any injury does arise?—I do not believe it in any other way than mechanically. I do not believe that copper dust would be worse than any other kind of dust.

4106. You have laid great stress upon the men climbing up the ladders, and you seem to think that a great deal of danger arises from their climbing so much as they do?—Yes, decidedly.

4107. Since the introduction of man-engines, do you think that the danger has been diminished?—Yes; and I have no doubt that it will be observed in the neighbourhood of St. Blazey that diseases of the chest will be much less in the next 20 years than they have been in the past 20 years.

4108. For how many years have man-engines been employed at Fowey Consols?—I cannot tell; but I should think for 15 or 16 years.

4109. Are the Commissioners to understand that you attribute the miners' disease more to their climbing and their exposure to the cold after they come up to the surface than to their working in what is called bad air underground?—I think that the climbing and the alterations in the temperature are two of the predisposing causes of the miners' disease, but to show that bad air is another cause of the the miners' disease, I may instance the Beam mine, where the ventilation was so badly attended to; but in the mines where I have been so much employed there are not so many cases of miners' disease as there were in the mines that are now abandoned.

4110. Do you think that the cases you have seen have arisen principally from the climbing and catching cold, or from working in bad air?—I think that all of them may tend to produce the disease.

4111. One cause seems to be bad ventilation; but I will set against that their rushing in to see the effects of the blasting; their moving rapidly up from below, their having to go frequently to the changing room, and being exposed to the cold, and their not over good diet. Now do you think that the miners' disease is more owing to the latter causes combined than to the want of ventilation underground?—I do not see how you can separate them; in the one case you predispose the miners to disease by bringing on inordinate action, and then you disturb the balance of the system, then again the men having to breathe impure air, that would tend to produce the disease.

4112. In those mines in which you are now extensively employed, is there much bad air?—No, I think that the ventilation, generally speaking, is very good.

4113. Are there many bad ends?—No; now that our agents have paid great attention to ventilation, I do not think that there is nearly so much bad air as there was formerly, and I do not hear it so frequently complained of.

4114. You have stated that the men being eager to effect a communication rise sometimes, and sink in others, in order to make a communication as rapidly as possible, but that notwithstanding that, some time will elapse before they can effect the communication. In that case do they resort to artificial means for the purpose of supplying air?—Invariably.

4115. They force in air?—Yes.

4116. Until natural ventilation is effected?—Yes, that is the case.

4117. Then does not great danger sometimes arise from the men having a long way to go to the changing houses, for example, in an extensive working where the labour is being carried on at a distant part, the old changing houses are allowed to remain in order to save expense, no fresh ones being erected near to the men as they ought to be?—That is the case sometimes; they could not be always building changing houses for every shaft that is put down.

4118. When the men quit their ends do you think that in well-regulated mines the men congregate in the open shafts near to the surface, and there remain until the bell rings, not mounting upwards for fear of being fined?—I do not think that that is the case,

not to accumulate in large numbers. I believe that they sometimes come up, and if they find they are a little before the time they might wait, but not in great numbers together.

4119. In large mines is there a debtor and creditor account kept as far as the miners' club goes?—Yes.

4120. Generally speaking how does the account stand, in favour of the miners or in favour of the mine?—There is always a surplus, in every case with which I have been acquainted, in the fund.

4121. You have drawn a very clear distinction between bronchitis or miners' consumption and true consumption; but I suppose that if a medical man came from a distance unacquainted with the miners' disease, he would be very apt to mistake the miners' consumption for real consumption, judging by the appearance of the men?—Yes, I had a long correspondence with a very celebrated consulting man in the West of England with regard to a case of the kind. He came and saw the case with me, and he said, "Surely this is a case of phthisis—the symptoms are" so and so. I said, "No, this is a case of what we call miners' consumption." He examined the case, and he could find nothing but the general symptoms of bronchitis, judging by the ear; but the next morning he was so satisfied that it was a case of real consumption that during my absence down stairs he actually discovered in his own imagination a cavity. He came down stairs, and he said, "I knew that there was a cavity in that man's lung," referring to the expectoration. I said, "I beg your pardon, there "is no cavity there, I have examined the man from "day to day, and whatever you may have heard "there is no cavity, come back with me and let me "hear it myself," but he could not it find afterwards. He was so convinced that it was a case of phthisis that he brought his stethoscope to hear what did not exist, which he admitted. I think that that shows strongly the view that a medical man might take who was not accustomed to these diseases, or accustomed to the stethoscope.

4122. (*Mr. Holland.*) Is it of common occurrence to mistake one disease for the other?—I think that these cases are very commonly called cases of phthisis.

4123. (*Mr. Austin Bruce.*) You have stated that you have often heard complaints made by men engaged in working upon a rise of ringing in the ears?—Yes.

4124. Are those workings in portions of the mines which are reached for the purpose of ventilation by artificial means?—Yes.

4125. If sufficient ventilation were supplied there would be none of those painful sensations felt?—No; but as I have stated before they very often use wooden pipes to carry in air, and those wooden pipes become damp, and there is a difficulty then in throwing in pure air, as it takes in too large a quantity of moisture, and in a close place where there are men breathing and candles burning there is such a consumption of the atmosphere that you cannot have it so pure with regard to the oxygen as by natural ventilation.

4126. Have you had any experience in mining in addition to your medical experience?—Yes.

4127. But only as a shareholder?—No.

4128. Do you often go underground?—No; I have not been underground for years past.

4129. Do you believe that in all cases the close ends are ventilated artificially?—I speak from my own experience here in the mines, and I know that that is the case, that means are always adopted where they can be to do that, perhaps a little more attention might be necessary, for they know the means, and they have it in their power to adopt them if they please, and if the men complain much I think the agents would be sure to do it.

4130. You have described very graphically the exhausting labour of boring, and the great muscular strength it requires?—Yes.

4131. Do you believe that where that kind of work is pursued the supply of air is always as much as it ought to be for the men so engaged?—In many places the air, I believe, is as good as it is here where that operation is going on.

4132. You say "in many places?"—Yes.

4133. But when you say "in many places" you exclude other places?—I cannot speak of mines in other parts, but I have no doubt that the same means are carried out in other parts as are carried out here; but I meant in many places in the same mine. In the rises I do not believe it is possible with our present knowledge of ventilation to get the air there, as it is possible in other places where a current of air is carried in from the end of the shaft.

4134. You have stated that a man may work on for some years while the miners' disease is establishing itself?—Yes.

4135. To the best of your belief are there any men under your charge at this moment in whom the miners' disease is forming?—I have no doubt there are; but in answering the question off-hand I cannot at once recall cases to my mind. I have two men who are now home suffering from it, but they are advanced cases. I have no doubt that I could find many incipient cases of the miners' disease.

4136. Men whom you would gladly treat if they had the prudence to come to you and describe their symptoms?—Yes; but they are not sufficiently ill to lay up from work; they do not like taking medicine unless they get a little cold, and then we give them some medicine.

4137. They are not sufficiently ill to be induced to come to you, but are they sufficiently ill to induce you to advise them to come to you if you were fully acquainted with their condition?—If they did perhaps I should order hygienic treatment which they would not adopt.

4138. But still some treatment would be necessary?—I should advise them not to work in poor air, or not to go down too deep, and not to climb.

4139. You stated that you believed that some of the bad effects arising from working in the close ends were due to the chemical action of the gases?—No; I beg your pardon, I stated that the air was heated in the ends from the chemical action going on in the lodes as well as from a want of ventilation.

4140. You stated that there was, in your opinion, no remedy for that chemical action?—None; of course if you carried in more air you would take away the excess of heat.

4141. A larger supply of air would neutralize the ill effects arising from the chemical action?—Yes; it would make the hot atmosphere colder by its obtaining an equilibrium.

4142. Supposing the thing were feasible, it is the duty, is it not, of those who conduct the ventilation to apportion the amount of it to the state of the mine, and the danger incurred by the workmen?—That I believe is pretty well attended to, I do not think that there is much to complain of as to that in our mines at present.

4143. If the effect of these chemical changes could be neutralized by a larger supply of air, and they were so neutralized, would not the danger then disappear?—What I say is this, that there is a chemical action going on in the lodes where there is an end driven into them, and the chemical changes that take place in it will go on whether there is ventilation or not, and those chemical changes are one of the sources of the hot end; it is not merely from bad ventilation.

4144. You will, I presume, admit that the evil effects of such chemical changes may be neutralized by a liberal supply of fresh air?—As far as the cooling of the end goes.

4145. Only so far as that?—Yes, there are no gases thrown out which are injurious by decomposition in the lodes.

4146. Do you believe that the cooling of the air in those places is necessary to health?—Certainly; the men would rather work where the air was moderately warm than where it was excessively hot.

I should say decidedly that it would be better for the men if they were working in a more equal temperature.

4147. Upon the whole, do you think that the tributors suffer more in their health than the tutworkmen ?—I have suggested that there should be statistics prepared upon that subject. I think that one would be found to be shorter lived than the other, but I cannot say that such is the case.

4148. Your reason for thinking so probably is, that the tributors usually work for a greater number of hours ?—Yes.

4149. I suppose it may be assumed that, as a general rule, they work in better air ?—I should say so, decidedly.

4150. You have made an excellent suggestion which was that after the men have fired a shot and retired, they should occupy themselves by turning a fan, instead of standing still and catching cold ?—Yes.

4151. Have you ever known that done ?—No, but I cannot say that it is not done. I believe that they very often have a boy who drives those fans to send in the air, and then they come out, and they take the opportunity to sit down on a little bench for a time to eat what they have, or to smoke.

4152. In those cases you would suggest that they should employ themselves by turning the fan in order to keep themselves warm, rather than for the sake of supplying air, which is already done by the boys ?—Yes, but I think that a man would turn it better than a boy.

4153. You have stated that the labour of a miner is one which requires a generous supply of food ?—Yes.

4154. And you have further stated that the sort of food the miners require is not of a fatty kind ?—I mean not to generate fat. I should say that they do not want a quantity of exuberant fat about them.

4155. What kind of food would you especially recommend for them, within the limit of their means ?—I think a limited quantity of animal food, but the great defect with regard to the miners, I think, is not in the character of their food so much as in the careless way in which it is cooked for them.

4156. Have any efforts been made to bring to the knowledge of the miners the kind of food that is best adapted for them, considering the nature of the employment ?—I am not aware that there have been.

4157. Do the miners attend lectures ?—No ; in fact it is only recently that they have had an opportuntity of doing so.

4158. But they have opportunities now, have they not ?—Yes, to a limited degree, but they do not attend to any great extent.

4159. Are they, generally speaking, sufficiently well educated to follow a lecture that is delivered in simple language ?—Not the kind of lectures that are usually given, which are generally more adapted for men who have been previously educated.

4160. I understood you to say that the habit of climbing made the men much more sensitive to the effects of any bad air ?—I should say that anything that breaks the circulation, and affects the lungs, which it must necessarily do, where there is increased respiration and circulation at one time, and then they fall down to the ordinary level afterwards ; from the sudden alterations in the structure, a man would be more predisposed to any disease arising from the breathing of bad air or deleterious gas.

4161. I presume that the bad air would render the climbing more injurious ?—Yes, as the bad air acts and re-acts the man's lungs would become contracted in a degree, and he could not take in so much air at a time, and he would have greater trouble in breathing.

4162. Upon the subject of clubs, do you think that generally speaking the money that is deducted from the wages of the men is either funded or that an accurate account is kept of it ?—Yes ; in all the mines. I would not say that in every small mine, where perhaps there are only a few men, there is such an account kept as there might be, but as a rule I think that all the books in the mines with which I have been connected as to the club account are very justly kept.

4163. Have you thought of any plan for preventing the consequences which you have mentioned, upon a mine being abandoned, and funds being still due to the miners ?—My own notion is that yearly all mines should send in a statement to a central board—say to the Vice-Warden's Court in Truro, or to any other place that might be determined upon—and that a debtor and creditor account should be given of all the mine clubs, and that upon the work in a mine coming to an end any monies that might be left in hand should be redeposited or vested in a committee, and that upon the certificates of the medical men and agents saying that so-and-so has been injured, they should receive a certain amount of money, that is to say, the men who were not provided with the means then of working.

4164. That is to say, that the men who had been working in a mine that had stopped should have a claim upon the fund that remained at the time the mine was closed ?—Yes, and that all mines that closed should contribute to a central fund, and for this reason, that the men who have been working in a mine that is abandoned to-day have worked perhaps in a dozen mines before they have contributed to their clubs.

4165. (*Mr. Holland.*) You have given us rather a long list of mines with which you are connected ?—Yes.

4166. Are they all in this neighbourhood ?—Yes.

4167. Are the dwellings which are occupied by the miners on the whole a tolerably good class of habitation ?—Yes ; the fact is that our miners are very well housed here—we have several mines that have ceased working.

4168. You have made a very good suggestion, viz., that inquiries should be made into the health of the tutmen and of the tributors—do you think that that could possibly be done ?—Yes.

4169. Do the same men continue as tutmen or tributors for any lengthened period of time ?—Yes ; but the tribute man does not like to work at tutwork, and the tutwork man is not competent, although sometimes the tutwork man is obliged to work as a tributor, but not from choice.

4170. Do you think that the two classes could be separated ?—Yes.

4171. You have stated that in your opinion the miners' complaint is not the same as tubercular consumption ?—Yes.

4172. But I suppose there is some tubercular consumption among them ?—Yes, but I do not think that the miners, as a class, are much more subject to tubercular disease than other classes of people.

4173. Do you not think that they are less subject to tubercular disease than other men ?—In giving an answer without having made any previous calculation, I should say that they were about the average.

4174. Do you happen to know that the age at which common consumption is most frequently fatal is under 35, and that there is less consumption among miners than among other males in England of the same age ?—Since I came into this district I have heard questions put as to the miners dying from consumption. I have been reflecting upon the subject, and my present notion is that I do not observe phthisis at all more, if so much, as amongst other classes.

4175. It is a statistical fact that a smaller number of miners die of consumption below the age of 35 than of other males of the same age. May it not therefore be presumed that the miners suffer less from tubercular consumption than other males ?—Yes, decidedly. I have not a doubt about that in my own mind, nor as to the nature of the miners' disease.

4176. You have stated that miners' consumption is generally bronchitis ?—Yes.

4177. Do you not think that it is often emphysema? —Yes; we do sometimes find emphysema, but not generally; we do not look for sound and percussion as in emphysema.

4178. Is there not rather an excess of resonance in the chest?—It is not marked. In emphysema we should have more resonance, a clear sound of percussion.

4179. Is there not often tubercular deposit?—Not only that, but we find the stethoscopic symptoms to be in the lower part of the chest.

4180. The fact that miners' consumption is situate mostly in the lower part of the chest, whereas common consumption is almost always at the top of the chest, makes a clear distinction between the two diseases, does it not?—It is not only that, but all the respiration and all the sounds are different.

4181. The formation of cavities in the upper part of the chest, I believe, is rare?—Yes; I should call it phthisis if we had cavities, but as to the emphysemous state in miners' consumption, I can distinctly state that in the last stages you may have the whole of the chest involved, so that at the last you may find some degree of emphysema, but it is certainly not so in the earlier symptoms.

4182. If the disease was produced by climbing, would not emphysema be a likely consequence?—Yes, you might get a forced extension of the air cells, that is by fast climbing.

4183. You are probably aware that the proportion of cases in which there is spitting of blood in true phthisis is very large, about two out of three?—That may be so in some part of its course.

4184. Is there anything like that proportion, that is two-thirds of the cases of miners' consumption in which there is spitting of blood?—No.

4185. Is there one-tenth of them?—It is a very rare thing; we sometimes see small streaks, but nothing more; we do not get hæmoptysis.

4186. Is hæmoptysis a rare occurrence?—Yes; very rare.

4187. Is not that another strong distinguishing mark between miners' consumption and tubercular consumption?—Yes; but the cases are not at all parallel.

4188. Does miners' consumption generally begin with spitting as well as cough?—No; not in the beginning, there is very little, if any, expectoration.

4189. That is not common bronchitis?—The first symptom that we see is a tightness in breathing, before there is cough to any extent; the person is not laid up in the beginning with bronchitis.

4190. Would you not rather call it bronchial irritation, or bronchial inflammation?—It is a low kind of inflammation that is set up which is not accompanied with the general symptoms.

4191. Is there at first much pain with it?—No; they do not complain of pain.

4192. No pain behind the sternum?—No; they complain of a tightness as if there was a band round them.

4193. But no pain?—No; they may sometimes have a little pain.

4194. Does miners' consumption very frequently begin with cold?—It begins in a slow way, with difficulty of breathing and tightness at the chest without abundant expectoration, but it becomes purulent in the end.

4195. After the disease has apparently become severe, if the miner changes his employment, does he generally recover?—I do not think they ever lose it after the disease has set in. I think they are always subject to it more or less, and always liable to have colds set up.

4196. The miner seldom recovers when the disease is once established?—No.

4197. If he changes his work may he not live many years afterwards?—Yes, and so they do as miners.

4198. When a person is suffering from tubercular consumption does he ever live many years afterwards?—Not frequently.

4199. Do you not know as a fact that considerably more than half the persons who suffer from tubercular consumption die in the first year after the attack, whereas miners' consumption often lasts for many years?—Yes.

4200. Does not that also show the strongly marked difference which exists between the two diseases?—Yes, of course.

4201. Have many of your patients complained of breathing in cold damp, as they call it?—I have heard some of the men who have worked in the granite mines in Beam, for instance, say that they have been breathing cold air.

4202. Mr. Lanyon divides the cold damps under two heads; he says, "Under the first we may place "all those in which carbonic acid is found to exist in "excess, forming a variety technically called cold damp "by the miner, found generally in shallow levels in "which granite or soft killas abounds. The effects "on the system are those in a certain degree which "are well known to be occasioned by carbonic acid, "first a sensation of coldness, quickly succeeded by a "giddiness and pain of the head, sickness, prostration "of strength, particularly of the knees, tremors, and a "most unconquerable disposition to sleep; to over-"come which and the coldness, the men are obliged "to work most actively and perseveringly." In your judgment is that a fair description?—I never heard our men complain so much as that, if they did I should suppose that they had been in bad air; into an old shaft that had not been worked; they are such symptoms as they describe when they go into a place of that kind, but I never knew our men working ordinarily complain of those symptoms; a man could not work with such air, and I can understand impure air producing all those symptoms, but not where any of our men work in this district.

4203. Such symptoms are very rarely produced, they are not common?—No; certainly not.

4204. Mr. Lanyon again says, "The general cha-"racter of the compounds to be classed under the "second head differs very considerably from these. "So far from being cold, these produce a disagree-"able feeling of heat, are found in deeper situations "and in harder ground than the preceding, and owe "their statistics in great measure to the more fre-"quent employment of gunpowder; it is here gene-"rally that we are nauseated by the sulphuretted "hydrogen evolved by the empyreumatic fumes "already noticed, and by the animal effluvia which "must be exhaled in great quantities from bodies "undergoing the most violent exercise in a tempe-"rature equal to that of a vapour bath. This atmo-"sphere is loaded also with powder smoke, which "renders it so dense as sometimes to be absolutely "irrespirable." Is that, in your opinion, a correct description of a hot end?—We have none in any mine that I have been engaged in.

4205. Mr. Lanyon goes on to say that out of 312 miners, 100 have cough, dyspnœa, palpitation, or all. It that anything like the proportion now?—I should say there was not so great a proportion, not nearly so.

4206. He also states that out of that same number (312) 87 suffer from dyspepsia, or some other diseases of the digestive apparatus. Is that in your opinion true?—It depends to what extent it goes. The miners very often complain of slight symptoms of indigestion. I should not say that there was so large a proportion.

4207. He further states that very nearly a tenth of them suffer from chronical rheumatism?—That certainly would not apply to this district.

4208. And 35 have had spitting of blood from the lungs at different periods of their lives?—There is no such proportion here. That is my opinion; but I am really answering without having kept tables. I certainly should say it was not so.

4209. (*Chairman*). You have stated that there are several who have upon them incipient miners' disease

St. Austell.

Mr. J. Pearce.

21 April 1862.

to whom you would recommend hygienic treatment?—Yes.

4210. How many have you under your charge at present?—I should think perhaps 400.

4211. Can you detect incipient miners' disease without making a minute examination?—The fact is, that I can detect it very easily in the breathing without examining them, when they have the first symptoms of this bronchial disease there is a hesitation in their breathing during the time they are talking.

4212. You have stated that in the mines with which you are connected there are some ends where the air is poor, and that means are taken to supply ventilation. Can you say what means are taken to supply ventilation?—It is generally with pipes or a fan, and sometimes with doors. I think at other times they use a falling stream of water.

4213. Is there an air engine attached to the steam engine?—I am not aware of that.

4214. Then it is merely where water is not used, to improve the circulation of the air below?—Yes, by using a fan.

4215. The means are below and not above?—Yes, it is not air brought from the surface.

4216. You have stated that although the men do not in large numbers wait upon the ladders in the shaft for fear of being spaled, yet still when they do wait, they would be likely to take cold?—Yes, especially if they had been climbing; if they come up by the man-engine they are not so likely to catch cold.

4217. Are you of opinion that the infants of miners are more weakly at birth than others?—Yes, I think that there is a great mortality among the children of miners; more so than among the children of the agricultural population.

4218. Do you think that there is a greater difficulty in rearing them?—Yes.

4219. (*Mr. Holland.*) Does that occur before or after the weaning?—After the weaning.

4220. What do you think that arises from?—I think partly from their food and from there being very little care taken of them.

4221. A surgeon of great experience informed me that he thought it arose from the bad cooking of the mothers?—I think that they do not keep their houses very neatly, as I have already stated, and I think I can generally tell a domestic servant from a mine girl who has become a wife.

4222. Have you noticed a difference in the comparative health of the children born of miners' wives who have been bal girls, and those who have been domestic servants?—You can tell the difference in the children. The latter are better clothed; there is more cleanliness visible in a house, and more care is taken of their children. I do not mean to say that there are no bal girls who do not make good wives, but I am taking it as a general rule.

4223. Are there many miners who have gardens in which they work?—Yes; and there are many of them who will go out and work between their times. I have a man who comes sometimes and he gets 7*s.* or 8*s.* a week from me for coming and working in my garden, he has done that lately.

4224. Is that a common practice?—It is not common to go out to work, but they cultivate gardens for themselves.

4225. Are those men who work in gardens more healthy than those miners who do not?—No; I should not say so, in fact this man is an example of an early stage of miners' consumption, you can see it by the catching in his breathing.

The witness withdrew.

Mr. John Berryman examined.

Mr. J. Berryman.

4226. (*Chairman.*) You are a medical man residing in St. Austell?—Yes. I have practised here about 12 years. I have not been surgeon to any mines of importance, but I have been parish surgeon during the greater part of that time, and from that circumstance I have derived what little knowledge of the miners' disease I possess.

4227. You refer to cases which have been brought under your notice in the parish?—Yes; and generally speaking they are in an advanced stage of the disease; occasionally I meet with them in an earlier stage, but not often.

4228. You say in an advanced stage of the disease, what is the disease?—I entirely agree with what Mr. Pearce has stated, that there is quite a distinction between tubercular phthisis and the miners' disease, and that they are two distinct disorders. I believe that the foundation of the miners' disease is at first bronchitis, and that repeated attacks of that bronchitis leads to a disorganized state of the different tissues of the lungs, the bronchial tubes, and the air vesicles themselves. It is from repeated attacks of bronchitis, not one only, but repeated attacks of bronchitis, and a continuance of cough.

4229. If the miners left the work in which they are engaged with bronchitis, would they equally, if they caught bronchitis in any other occupation, bring on the same state of disease?—Not unless it was repeated, and then it would have that effect.

4230. Are you of opinion that working in the mines is likely to cause a repetition of that disease?—Very likely. I think that it is the nature of the occupation which causes repeated attacks, and I think, also, that climbing is an additional cause.

4231. Have you examined any of these patients especially?—Yes, I have examined their chests; we have but few opportunities of examining, and particularly of making post-mortem examinations.

4232. Have you had any opportunities at all of making post-mortem examinations?—No, I cannot say that I have had any of which I could give a distinct and proper history.

4233. Do you find that amongst any other class of the population anything like the same kind of disease prevails?—We find the same kind of disease occasionally among the people who have been exposed to similar causes.

4234. In your parish are the cases which mostly come under your notice those of miners?—Yes, it is a mining district hereabout, and those who come under my care are frequently miners who suffer from this disease.

4235. Do you ever meet with them in an early stage?—Yes, occasionally.

4236. Have you known any cases in which they have recovered?—Yes, but that is not in an advanced stage of the disease. I think that if they were removed to some other calling the disease could be prevented from proceeding to an extreme.

4237. (*Mr. Kendall.*) Generally speaking you agree with the evidence given by Mr. Pearce?—Yes, with this exception, that I think emphysema is a very common accompaniment of the disorder.

4238. (*Mr. Holland.*) Do you mean early in the case?—I think that the bronchial tubes get dilated from frequent cough, and that the lungs become emphysemous. I think so from seeing them frequently in an advanced stage, and from the various symptoms which are shown. I believe, with Mr. Pearce, that the thickened state, from the inflammatory substances which are thrown out of the tubes gradually increasing, is the primary cause of it.

4239. (*Mr. Austin Bruce.*) Have you instituted any inquiry into the comparative length of life among miners and the other part of the population?—I have no statistics to go from; it is merely from memory, but we know that we very rarely see an old man a miner; they become disabled and unfit for work before they get to between 50 and 60. Some of them work on, but they are generally men of very

sound constitutions, who have been, perhaps, not subjected to such powerful exciting causes.

4240. The number of hours during which they work per day is very moderate, is it not?—They work for eight hours in the 24, sometimes by day and sometimes by night.

4241. Then their work must have something to do with the causes affecting their health, arising either from its severity or the conditions under which it is carried on?—I think it is from the nature of their occupation.

4242. What should you specially point out as that part of their occupation which produces the most injury?—I should say, first, it is from working in bad air, and from their coming up in an exhausted state from their work; coming out of a hot atmosphere and being subjected, under those unfavourable circumstances, to external cold, which is very likely to produce bronchitis and lung disease.

4243. I suppose that a large portion of them suffer from a combination of those causes?—Yes. I think that the irritating effect of the powder smoke is another cause by irritating the mucous membrane of the chest.

4244. (*Mr. Holland.*) Are you of opinion that the disease generally is at the base of the lungs, and not at the top of them?—I do not think that the lung tissue is affected. I think it is principally confined to the tubes; first, the tubes and cells. I think that a mistake frequently exists upon that point. Sometimes there is inflammation of the lung tissue, and there are cavities, although there are no tubercles existing that may be the cause of tubercular phthisis, but you get stethoscopic symptoms; a cavity without tubercles being present.

4245. A dilated tube may be so much enlarged as to give forth the resonance of a cavity?—Yes, but that is rare.

4246. Do you think it is an ulcer of the substance of the lung?—Yes.

4247. Is hæmoptysis a rare occurrence?—I think that pure hæmoptysis or spitting of blood is rare, but frequently they have hæmorrhage. If I had a case where there was distinct hæmoptysis, I should come to the conclusion that they had tubercular phthisis.

4248. Is distinct hæmoptysis a rare occurrence?—Yes.

4249. Much more rare than in the ordinary run of consumptive cases?—Yes, decidedly.

4250. (*Mr. Kendall.*) Have you ever been underground?—Never.

The witness withdrew

Mr. William Pace examined.

4251. (*Chairman.*) You have charge of the district adjoining that of Dr. Tayler's?—Yes, I have.

4252. Will you state to the Commissioners the number of miners in your district?—I should say about 2,000.

4253. And those are more or less under your charge?—Yes, together with Dr. Tayler.

4254. How many are under your own particular charge?—I should say 1,500.

4255. Have you at this moment many patients?—Not many.

4256. Can you state about how many are under your charge?—Very few indeed; I do not think I have now half a dozen.

4257. What is the disease under which those miners are suffering?—One man has been home with miners' disease, and for the last 12 or 13 years he has been receiving miners' pay from the club; sometimes the poor fellow is better, and sometimes he is worse. Then there is another man who is suffering from miners' disease, but not so badly; he occasionally works.

4258. Do you think that there are many men amongst those you have mentioned who, if examined would be found to have upon them incipient symptoms of miners' consumption?—No.

4259. You probably heard Mr. Pearce state that he could tell when a man had upon him the miners' disease in an incipient form, although not without minute examination?—I could very soon detect it if they came to me.

4260. Do they come to you in that state?—Sometimes; not in an incipient state. They have become so much improved in health in the last few years that they are quite a different race of men to what they were when I first came to the district 25 years ago, and that has taken place since we have had the mines better ventilated, and have had the man-engine at the mines.

4261. How long has the man-engine been employed?—About eight or nine years.

4262. At which mine is that?—At Fowey Consols.

4263. Is there a man-engine at the other mines?—Yes, there is at Par Consols.

4264. How long has it been there?—Only a short period.

4265. Do you know how long it has been there?—Within the last year and a half.

4266. Have you observed any difference in the health of the men as between Fowey Consols and Par Consols, or before and after the man-engine was put up at Par Consols?—Not any.

4267. At Par Consols the men had to climb to the surface by the ladder?—Yes.

4268. Until within about a year ago?—Yes.

4269. What height had they to climb up at Par Consols?—I think about 200 fathoms, and I think that the adit is about 30 or 35.

4270. The men at Par Consols having to climb by ladders to the surface were not in a more unhealthy state than those at Fowey Consols?—No.

4271. Have any new means been employed for the purpose of ventilation in the mines since you came to the district?—Yes, a great many.

4272. What is it that, in your opinion, has occasioned the improvement in the health of the miners, is it ventilation?—Yes, better ventilation and the man engine; the miners altogether are better in health, and there is more morality amongst them, they are better conducted than they were.

4273. Are they less addicted to intemperance?—Yes; that has been left off very much indeed.

4274. What induced the miners to leave that off?—I cannot say that; they are not decidedly teetotallers but they do not drink so much as they did.

4275. Are there many teetotallers among them?—A few.

4276. The man-engine could only have had an effect in one mine in improving the health of the miners?—Yes, but they are more careful in climbing; they do not climb so hard as they used to do many years ago.

4277. How is it that if the man-engine has had the effect of improving their health that any of the men have climbed for those two years during which the man-engine has been in operation, and that in Par Consols an improvement has also taken place?—It is from that cause that they do not climb so hard; I have advised them not to do so, and they have attended to it.

4278. You think that if they did not climb so rapidly, it would not be injurious to their health?—Not if they took their time in coming up.

4279. Would there be any difference in the effect of the climbing whether they had been working in poor air or in good air?—Yes, in poor air it would produce a great deal of exhaustion with them.

4280. With regard to the miners' disease, what do you consider that proceeds from?—I think that it comes on from cold, but they are more careful than

St. Austell.
Mr. W. Pace.
21 April 1862.

they were. Formerly they would come up from the hot levels, and wash their breasts in cold water, and sluice themselves over with it, and put their feet and legs in cold water, and wash their arms in it; but now they do not do that, they now use warm water.

4281. Is the warm water provided for them?—Yes, they may get it.

4282. But is it provided for them?—They can get it when they like from the engine.

4283. The men can fetch it in from the engine?—Yes.

4284. Would it not be better to have a regular washing place provided for the men?—It might be; but perhaps some of them would not have recourse to it.

4285. Do you consider the miners' disease a form of bronchitis?—Yes. I believe that it commences with bronchitis.

4286. Did you hear the evidence given by the last witness?—Yes.

4287. Do you concur with him?—Yes. I believe that it may terminate in true consumption where there is an hereditary disposition to it.

4288. But if there is not an hereditary disposition, then what should you say?—I do not think it would so terminate with care.

4289. Would the symptoms be similar?—Yes, they would.

4290. So that you could distinguish between the two?—Yes, decidedly.

4291. (*Mr. Austin Bruce.*) You have given a most gratifying account of the state of the health of those who are under your charge. Do you believe that the miners are as healthy and as long-lived as the population who are not employed in mining?—I think so about this district. I saw a man yesterday, who was 72 years of age, a miner, and who went underground at the age of 11, a hearty, hale-looking man.

4292. He must have worked for a great number of years during the time when the mine was less well ventilated, and when there was no man-engine?—Yes.

4293. So that his constitution must have been a remarkably sound one?—Yes.

4294. Taking the average, have you at all compared from the materials which must exist in the neighbourhood, the length of the miners' life as compared with that of the agricultural population, and those engaged on the surface of the ground?—I think that they are about equal now. We have many miners in our neighbourhood now who are working, and taking their duty, and performing it as well as young men; they are between 50 and 60.

4295. Do you speak now from having observed more numerous instances than formerly of long-lived miners, or do you speak from any analysis you have made of the burial register?—I speak from my own observations of men residing in the neighbourhood

4296. Where are the greater portion of the miners, who are under your charge when they die, buried?—In St. Blasey.

4297. In the parish churchyard?—Yes.

4298. Are others buried elsewhere?—Yes; sometimes they are taken to Tywardreath.

4299. But the greater part are buried in St. Blasey?—Yes.

4300. Would it be too much trouble for you, occupying as you do so important a position among the medical men in the district, to analyse the burial register in order to ascertain whether your impression as to the longevity of the miners is correct?—It would be no trouble at all to do that.

4301. If you would be so kind as to do so the Commissioners would all feel much obliged to you?—I will do it. A great boon to the miners employed in our mines in Par Consols, West Fowey, and Fowey Consols, is that the surgeons have unlimited power to order them wine, porter, or ale or anything that they may think necessary for them; the adventurers allow that.

4302. In fact it may be assumed that the miners at West Fowey, Fowey Consols, and Par Consols, are working at least under as favourable conditions as any miners in Cornwall?—Yes.

4303. (*Mr. Holland.*) Do you agree with the other witnesses as to the difference between miners' consumption and common consumption?—To a certain degree I do.

4304. Do you agree as to its being more in the lower part than in the higher part of the lungs?—Yes, in its commencement it is so.

4305. Is hæmoptysis comparatively rare in miners' consumption?—It is very rare now, or within the few years, since we have had the man-engine at Fowey Consols. Before that we had many cases of hæmoptysis.

4306. (*Chairman.*) Did you observe that the same change took place at Par Consols where there was no man-engine until last year?—There were very few cases indeed, it was the depth of the mine, at Fowey Consols it was so deep and hot.

4307. Then the miners at Par Consols never suffered so much as those at Fowey Consols?—No.

4308. (*Mr. Holland.*) Are you acquainted with any of the miners in the rest of the country?—No; they occasionally come to me for advice from distant parts, but very few.

4309. Have you any means of knowing whether the miners at Fowey Consols are much more healthy than those of the rest of the country?—No.

The witness withdrew.

Mr. Richard H. Williams examined.

Mr. R. H. Williams.

4310. (*Chairman.*) Will you state to the Commissioners the name of the mine of which you have charge as captain?—The Charlestown united tin mines, and the St. Austell Consols mines; those are the largest mines.

4311. Have you charge of any others?—There are two smaller mines; we are only working above the adit now with some few men.

4312. Have you worked underground yourself?—Only for a very short time, a month or two. I have not worked much underground as a miner.

4313. How did you obtain your experience with regard to mines so as to be appointed manager?—I had been at the mines studying for a number of years before I became manager.

4314. How many years have you had charge of the two principal mines which you have named?—Of one mine about 12 years, and the other since its commencement, of the Charlestown mines about three years.

4315. How many men are there employed in the large mines with which you are connected?—We have 243 men underground in the Charlestown mines.

4316. And in the other large mine how many?—In the other mine we have 126 men employed underground.

4317. What is the depth of the Charlestown mine?—The bottom of the mine is now 140 fathoms deep under the adit, making about 160 fathoms.

4318. And what is the depth of the other?—That is comparatively shallow; it is only 80 fathoms from the surface.

4319. In the first mine is there more than one shaft, or how many are there?—We have six shafts in the Charlestown mine, and we have two communicating with the bottom of the mine, or the next bottom level at the St. Austell Consols mine.

4320. Are you now driving any levels where the air is what is termed poor?—We are driving on to the 50-fathom level, and also the level at the 124 fathoms, at the bottom of the mine. Those are what

we term the closest ends, and most requiring ventilation.

4321. Is there poor air there?—It requires a moving atmosphere in all those places.

4322. What means do you adopt to supply air?—I have adopted for some years in the mines a water jet with very great success, that is driving in water by means of high pressure, and the water is discharged through a small rose, similar to the end of a watering-pot, and that is thrown in through a larger wooden pipe, which forms a kind of natural vacuum, and so the supply is kept up to the end by continuous tubes.

4323. Made of wood?—Yes, all made of wood; or we could use cast iron, or galvanized iron; we find that the wood absorbs the oxygen to a certain extent, and consequently deprives the air of it.

4324. As you go on, do you extend your tubes?—Yes.

4325. Is it by ladders that the men ascend from below?—Yes.

4326. Have you ever thought of any means by which they could be conveyed to the surface without climbing up the ladders?—Yes, I have; I was created an associate of the Royal Institution of Cornwall for a paper that I wrote, and a model that I exhibited for lifting miners out of the mines. It was by drawing them up in a skip with a safety catch to it.

4327. Has that mode been adopted?—Yes, it has been. I threw the plan entirely open to the mining population, and it was taken up by some persons, and some little improvements have been made in it, and it has been adopted in one or two mines, for example, in the South Francis mine the men come up in a skip, and I have inspected it.

4328. Is that mine worked according to your own notion?—Yes.

4329. Has this plan been applied to your own mine yet?—No.

4330. Have you recommended that it should be used there?—I think that in putting up a machine in our own mines I should put up one of the ordinary man-engines like that which is used at Fowey Consols, for I think that it is more permanent, and more to be trusted to; I have been over them both. I have been to the bottom of Fowey Consols, and I learnt most of my mining there.

4331. Which is the most expensive of the two plans?—The man-engine would be considerably more expensive to the mine.

4332. Have you ever calculated what the expense of a man-engine would be if applied to your mine?—Yes; I should think it would be perhaps about from 1,000*l.* to 1,200*l.*

4333. Have you recommended that it should be adopted?—It has been suggested; I have not recommended it. We are only just opening the mine, we have not drained it very long. Had we constructed the whole of the works most likely we should have adopted some means before this.

4334. Has any accident happened from the use of the skip at South Francis mine?—I think that one man has been killed. I condemn the practice of using the skip as it is now done. I think that if the skips are to be used for drawing up the miners there should be duplicate ropes, not the same that they are drawing up with, because those catches might slip at any time.

4335. Are you acquainted with the man-engine sufficiently to say whether any accidents have happened?—No accident has happened at Par Consols or at Fowey Consols, I think, to either of them; but on its first introduction it was rather dangerous; they had two rods working side by side, so that a man stepped from one moving rod to the other; but at Fowey Consols you step off on to a platform which is fixed, and your attention is called only to one object instead of to two. I have come up by that with very great ease.

4336. Do you think that the man-engine can be applied to all mines?—I think that to all deep mines it should be applied, but in shallow mines it would be a question of very great expense. The operations of mineral mining are peculiar; it sometimes occurs at the first onset of a mine that all the establishment, the plant, &c., is erected on one spot, and after some time the most productive ground is found to be perhaps three-quarters of a mile away, and the works would have to be reconstructed. I think therefore that a mine should be established before a man-engine is resorted to.

4337. What would be the cost, by your plan, of a skip?—The cost of the attachment—merely catching the skip is very little—of course the same guide and skip rope that is in use in the mine would be applicable for drawing up the men.

4338. But that is supposing that you adopted the same means of draught as that by which the ore is brought up?—Yes; I do not condemn the plan exactly, I only think that where these skips are used for drawing up the men, duplicate ropes should be kept purposely for that; the same machinery would be safer if there were good duplicate ropes for drawing up the men.

4339. You would propose that they should come up the same shaft?—Yes.

4340. But of course the machinery for bringing up the ore would be stopped at the time the skip for the men was coming up?—Yes.

4341. Therefore the expense of it would be only the extra ropes?—Yes.

4342. Might not it be, at all events in the first instance, too expensive perhaps to adopt the man engine?—I think for shallow mines I should wholly condemn, but not for deep mines.

4343. How could you put a man-engine into a shaft that was not straight?—There would be a certain amount of difficulty, but I think that could be overcome by the handle being at an angle, and taking a shorter lift, the platform being at the same angle, so that the rod would take the line of the shaft; but the holding part must be made to fall like an inverted cone, and the platform across the shaft must be put in as before.

4344. So that the man-engine could be adopted although there were angles in the shaft?—Yes.

4345. (*Mr. Kendall.*) You do not speak as a working miner?—No.

4346. You have been, as I understand, connected with mining from your boyhood?—Yes.

4347. And you were first at Fowey Consols?—Yes.

4348. What is your special occupation now?—I am only a mine agent.

4349. Have you the command of the whole?—Yes.

4350. Have you given your attention a good deal to machinery for the purpose of ventilation?—Yes, I have, and to mining operations as well.

4351. Do you go underground frequently now?—I go underground three days a week, sometimes four, and I have gone underground six days a week.

4352. Do you set the ground yourself now?—Yes.

4353. You say that you have given your attention to the subject of ventilation?—Yes, I have.

4354. Has the ventilation of mines been improved since the time you can recollect?—I think that the plan I am now adopting, and have adopted for some years, has been approved by Captain Charles Thomas; he inspected the mine, and he said that he believed a level could be driven any distance with that, that is by a water jet.

4355. Is that different from the old water jet?—Perhaps it is not. I do not claim exactly the merit of inventing the thing, but I claim the introduction of it in the Cornwall mines.

4356. To what distance does the water jet enable you to carry air in?—The furthest distance has been 100 fathoms.

4357. Where is that?—At St. Austell Consols.

4358. Is the air very pure in the end?—Yes, that which comes in the pipe.

4359. You mean the air that is sent in ?—Yes.

4360. Does it enable you to burn a candle without any perceptible difference ?—Undoubtedly it does in the end.

4361. What do the men think of that ?—The men say that they never saw such a machine before.

4362. Are they pleased with it ?—Yes. I set a pair of men the other day to raise a shaft from the 85-fathom level to the 70 fathoms.

4363. Fifteen fathoms ?—Yes ; it is 15 fathoms perpendicular, but this rise has gone up in the under lie, so that the measure of the rise was nearly 20 fathoms.

4364. What is the distance from the rise to the draught ?—The last place where there was good air was at 80 fathoms, and I put in this machine, and the air in the top of that rise was as pure as it is in this room, except the heat from the candles.

4365. What was the expense per fathom of doing that ?—The iron pipes cost us about 2*s.* 6*d.* a fathom, and the zinc pipes about 5*s.* a fathom; they are easily put together, they are all of iron like gas tubing, and they screw universally ; there is no trouble in fitting them, and two men in three days would put the thing in.

4366. What was the cost of keeping the action up ?—A powerful machine put in with an inch pipe and about a two inch rose with 16 holes, would cost us about half a stroke per minute to a 12-inch lift, or equal to about 400 cwt. of coals a day. The water is taken from a high level and conveyed down into the mine through a small pipe, the height gives the pressure, the outlet is much less in proportion, owing to the small hole, and that creates a jet. That jet is blown in through a large wooden pipe, and after being passed in some three fathoms the jet throws the water about three fathoms through this pipe, and consequently all the air is knocked out, so that it forms a sort of natural vacuum, and the air rushes in at the back, the draught is so great that it will put your candle out.

4367. You have stated that zinc pipes would cost you about 5*s.* a fathom ?—Yes.

4368. After your arrangements are complete what is the working cost ?—That depends upon circumstances.

4369. Do you employ a boy to watch it ?—No ; nothing but the men who go down to relieve look to it.

4370. Is it self-acting ?—Yes.

4371. What extra cost per month do you think accrues from the use of this machine in taking up the water that you throw through the jet ?—It requires a little explanation. I have a very powerful one now working at the 124 fathoms in the Charlestown mines, supplying seven men in the corps ; there are two men in the end, two in the cross cut, and three men cutting out the lode, and this is giving those men a full supply of air now. It cost us nothing as it is taken from a high level, and the water would fall from that level, and be conveyed down through wooden pipes to the 124-fathom level, for in case that machine was not working, the same water would have to be brought down to supply that lift. It occurs in the mines that we graduate our lifts in size as we go down a little smaller so as that each lift shall only be sufficiently large to take away the water, but it occurs at the under levels in the water time that the top water comes in and overflows the top lifts, and we have to work the engine much faster, consequently our bottom lifts go in fork ; that is, they have not a sufficient supply, and that injures the work, it forces the air, and causes a great concussion of the valves, we obviate that by having a wooden pipe from the top to the bottom ; it goes down, and it conveys a sufficient quantity of water.

4372. So that this machine costs you nothing when it is once in operation ?—Nothing at all, but in some mines it would, in some mines where they are driven up on account of pumping, every lift is sometimes full of a quantity of water, and to take away that would be an additional cost. When the engine is brought to its full maximum load the speed of it would entail a considerable amount of cost, and perhaps cost 20*l.* or 30*l.* a month, and that might endanger the machinery by forcing the engine faster than it would go.

4373. Under ordinary circumstances you are of opinion that when once you have incurred the expense of erecting this machinery, the sum of money required to keep it in working order would be merely nominal ?—Yes.

4374. (*Mr. Davey.*) In ventilating a level, which is the best principle to act upon, to extract the foul air, or to force in pure air ?—To drive in pure air, I think.

4375. Have you seen your plan tried in any other mine than your own ?—No.

4376. (*Mr. Kendall.*) Did the miners under you suffer much from foul air before you adopted this machine ?—We could not have done the work without it ; we must have had either that machine or some other, and I have found this most effectual.

4377. Did you use any other artificial means before you adopted this principle ?—Yes, I have used the fan machine ; I have had six boys driving the fan, two boys in each corps, each eight hours, and I find that those little boys flag at their work, the fan stops, they drive too slowly, and they do not throw in the air.

4378. Did those fans throw in fresh air ?—Yes ; I applied a little water wheel underground with very great success, and I think that has been done in Polgooth as well. I am now putting it into the 124 fathoms at Charlestown to drive the fan there, it is a water wheel, a 10-feet wheel.

4379. (*Mr. Holland.*) Are you now working the 80 fathoms with no other mode of ventilation but the jet ?—Yes.

4380. (*Mr. Austin Bruce.*) How long has this plan been in operation ?—I have worked it for about seven or eight years.

4381. After the account you have given of it, I presume that there is no close end to which it would not be applicable ?—I could not say that, because sometimes we have got a driving shaft, and where we have not got a skip rope or some means of steadying the kibble, if we bring our iron pipes down that shaft this thing would knock them out. A level driven from the driving shaft would not be so easily ventilated by that means if the ordinary fan could be used.

4382. Are you now working close ends under two systems ?—Yes.

4383. Are the men in your opinion in the one case able to work more vigorously than they are in the other ?—I think that they work more hours.

4384. Do they work longer than the ordinary eight hours ?—No ; but in the one case there is so good a supply of air, the current is so great that the smoke of the powder, after a hole has been blasted, is instantly blown away, while in the other case the draught is so little that the smoke is merely floating.

4385. In letting work do you believe that you are able to let it more economically to your employers in well-ventilated mines ?—Yes.

4386. Have you had practical proof of that in your own mine ?—Yes, I set a pair of men on Friday last at St. Austell Consols to cut through a lode. I gave them 30*s.* a fathom more than I should have given them if they had had a full supply of fresh air.

4387. How much would you have given them then ?—About 45*s.* a fathom, and I gave them 3*l.* 12*s.*

4388. If that is at all a fair instance to give the difference must be out of all proportion to the expense of erecting and maintaining such a machine ?—Yes, no doubt it is.

4389. Is it as applicable to the rises as it is to the close ends ?—Yes.

4390. It can be applied vertically ?—Yes.

4391. Have you done so ?—Yes.

4392. And always with the same economical

effects as well as the same healthful effects?—Yes. I put in a rise through to the Charlestown mines 20 fathoms, and I do not think that any other machine would have done it; we should have gone to the level and sunk part of the way, but we had the machine there, and so have risen part of the way.

4393. Has this machine been examined by other engineers in the district?—It has been examined by Captain Charles Thomas and Captain Mitchell.

4394. Has Captain Charles Thomas approved of it?—Yes.

4395. Has he adopted it?—Yes.

4396. (*Mr. Davey.*) Which Captain Richards do you allude to?—Of the Devon Great Consols. I sent him a drawing of it, and I showed him the plan; I also got part of the apparatus made by Mr. West, and sent it to him.

4397. (*Chairman.*) How long ago was that?—It was some three years ago.

4398. (*Mr. Austin Bruce.*) I presume that the larger the portion of the eight hours which a man can devote to his work the better for himself and for his employer?—Yes.

4399. The man-engine, I suppose, leads to that desirable result?—It certainly does for deep mines.

4400. Can you give any instances of the difference it has made to the miner from your own experience, that is to say, what amount of time, in shafts of an equal depth, would be saved to the miner by the use of the man-engine?—I have come up from the bottom, at Fowey Consols, with the man-engine in 20 minutes, the depth being 240 fathoms, and the adit being 40 fathoms, making together 280 fathoms; and if I had had to climb up by the ladders I should have wanted an hour and a half to do it.

4401. The saving of time is over and above the advantage gained to the men's health and strength?—Yes.

4402. In blasting are any injurious effects produced upon the health of the men by the explosion of gunpowder?—The combustion of the powder produces carbonic acid, which of course produces a sort of coma, or lethargy, or stupor, as that must be inhaled by the miner.

4403. Is there anything that you think is injurious to the health of the miner from the smoke of the candles?—I think that the most injurious effect of the candle is that it takes up the oxygen and leaves the carbon, of which there is an excess. I believe that Professor Phillips has spoken of introducing an apparatus for generating oxygen, but I think he is quite mistaken as to mining; what we want is a moving atmosphere.

The witness withdrew.

Adjourned till To-morrow at 10 o'clock.

Tuesday, 22d April 1862.

PRESENT:

The Right Hon. Lord Kinnaird, K.T.	H. Austin Bruce, Esq., M.P.
The Hon. A. Fulke Egerton, M.P.	H. P. Holland, Esq.
Nicholas Kendall, Esq., M.P.	Richard Davey, Esq., M.P.

The Right Hon. Lord KINNAIRD, K.T., in the Chair.

Mr. Francis Barratt examined.

4404. (*Chairman.*) In what mine are you engaged?—In South Crinnis.

4405. Do you manage that mine?—Yes.

4406. I believe you are one of the principal proprietors of that mine?—Yes.

4407. Had you ever the management of any other mine?—Yes; East Crinnis, Pembroke, and the Charlestown mines.

4408. Did you ever work in a mine?—Not in this county, but I have in Devonshire.

4409. In what description of mine?—A copper mine.

4410. What is the mine that you are now managing?—A copper mine.

4411. What number of men are employed in South Crinnis?—Not many; there are 72 underground.

4412. How many boys are employed?—Of boys and girls there are 63.

4413. Are they all employed on the surface?—Yes.

4414. Are there no boys employed underground?—I think not.

4415. Have you any fan engine worked by a boy?—We have occasionally, but very seldom; we have 22 men employed at the surface to work at the engines and other things.

4416. What is the youngest age at which a boy works underground?—I should think about 16.

4417. I suppose it is no advantage to them to work underground below under that age?—I think it is no advantage for them to work very early.

4418. What is the greatest depth that has been reached in your mine?—At present we are shallow, only 35 fathoms below the adit.

4419. Do the men ascend by ladders?—Yes.

4420. Have you ever seen any other means of ascent or descent adopted?—Yes.

4421. Where?—In the north of England.

4422. What are the means adopted there?—The men go down in a bucket.

4423. Would that plan, in your opinion, be applicable to the mines here?—No, I do not think it would.

4424. Why not?—I think that the men would not prefer it; they would rather climb the ladders.

4425. Would it be practicable to adopt it, as far as your experience goes?—I do not see any use in it in our neighbourhood.

4426. Would it not be an advantage in a deep mine to have some means by which the climbing up the ladders might be avoided?—Yes.

4427. Do you think that the means which you have seen used in the north would be applicable here?—I should prefer a man engine.

4428. But do you think that what you have seen in the north, might be applied here?—It could be applied certainly, but I think a man engine would be preferable.

4429. Why?—In this neighbourhood the stuff is drawn up by buckets, and unless there was a separate shaft, a distinct shaft, there would be danger from one bucket going up and the other coming down.

4430. There are two means by which the stuff is drawn up, the kibble and the skip?—Yes; the skip is not generally used in this neighbourhood.

4431. Do you see any advantage in the use of the skip?—Yes.

4432. What is the advantage of it?—There are fewer accidents, and less breakages, and it is drawn cheaper.

4433. Do you think there is any less chance of the stones falling out?—Yes.

4434. Therefore you think that there would be an advantage in using the skip?—Yes.

4435. In places where the skip is used, could not

some means be devised by which, the skip being attached to the same rope, the men could ascend and descend at a different time from the material ?—Yes ; I suppose it could be done.

4436. What is the objection to its being so used ?—The steam whim would be occupied in sending the men up and down, and there are so many various levels that they must stop at. By the man engine they could step out.

4437. But the men only go down at certain hours of the day, do they not ?—It is at six o'clock in the morning, two o'clock inthe after noon, and ten o'clock at night.

4438. It would only be necessary to stop the conveyance of the stuff upwards at certain times ?—Yes ; but it is not always that the whim is working.

4439. In a very deep mine, if there were means to enable the men to mount from the level at which the ore is put into the skip or kibble, would it not be a great relief to the men, considering the great height that they have now to ascend by ladders ?—Yes ; of course, in deep mines, but not in shallow ones.

4440. You have spoken of the man engine, are you aware that the men objected to that at first ?—I am not aware that they did.

4441. Do you know what the expense of erecting a man engine is ?—No, I do not ; we have never erected one, it would depend upon the depth.

4442. Is it applicable to any large shaft as at present sunk ?—The perpendicular shafts are the best, but I do not know enough of the subject, I have never had anything to do with it, I have only seen them.

4443. In the mine you have spoken of, I suppose there are no hot levels ?—No.

4444. Are there any ends in which the air is poor ?—No.

4445. Do you ever drive ends at any great distance from a shaft ?—Yes.

4446. At what distance from the shaft have you ever driven an end ?—200 fathoms.

4447. What means of ventilation did you adopt when you were driving away from the shaft ?—A brattice.

4448. From the shaft ?—Yes.

4449. Is that carried along the level ?—Yes.

4450. Is that made of wood ?—It is a soller, as we term it.

4451. Is it necessary when you have a soller to raise the height of the level ?—Yes.

4452. With a soller to what height do you drive the levels ?—Eight feet, six, or nine feet.

4453. Leaving for the sollers about two feet ?—Fully that.

4454. And that is carried on to the full extent to which the men are working ?—Yes ; within about two fathoms.

4455. Do not those sollers wear out very quickly ?—There is a rail laid on them.

4456. You do not use any barrows on them ?—Very rarely.

4457. With a rail upon them those sollers will last ?—Yes.

4458. Is the air passing through them at all affected by passing through the wood ?—We do not observe that.

4459. Does the wood soon get rotted through ?—No.

4460. What kind of wood do you use ?—Deal.

4461. I suppose that where you are working now is not a wet mine ?—No ; it is dry.

4462. Do you consider that the ventilation by that means is complete to the extremity of the end ?—Yes ; the current is either under the soller or over, because we have doors in the levels and at the shafts so as to change as the draught changes.

4463. Do you mean that the draught is affected by the weather ?—Yes, by the wind.

4464. How many shafts have you ?—Six.

4465. If the ventilation is much affected by the wind you then shut the door down in order to force the air down the soller ?—Yes ; either to drive the current over the soller or under it.

4466. Is your object to introduce fresh air by the soller ?—Yes. That is constantly going in over the soller or under the soller.

4467. In that change of the current of air is it changed from under to over, or from over to under ?—It is according to the wind.

4468. That is from the communication that the soller has with the shaft ?—Yes.

4469. Do you provide any accommodation for the men on their coming up from the mines ?—We have galleries about the smiths' shop.

4470. Do the men get a change of clothes ?—Yes.

4471. Are their clothes well dried ?—Yes ; they are dried in consequence of the fires that are there.

4472. Is the smiths' shop far from the footway ?—It is about 40 yards from it.

4473. Is there much dust created when the men are changing their clothes ?—No.

4474. Is ventilation provided ?—Yes.

4475. How soon is the smoke cleared away from the end to which these sollers are conducted ?—That will depend upon the strength of current ; sometimes perhaps it may take three or four minutes, and at other times it may take three times that length of time.

4476. What should you say would be the longest time before it could be cleared away ?—I think that an end would be clear of smoke in about 15 or 20 minutes.

4477. Is the current also affected by the temperature ?—Yes.

4478. On a close heavy day I suppose there is not much circulation ?—No.

4479. Have you ever, in other mines, seen any other means adopted for ventilating close ends ?—Yes ; by a waterfall forcing in air.

4480. Is that in your opinion a good method ?—Yes ; no doubt of it.

4481. But that depends, does it not, upon your having the means of getting water ?—Yes.

4482. Will you describe to the Commissioners how that is done ?—It is by a perpendicular pipe, and the water falling through it, the air is admitted in with the water, or we take it perhaps 15 or 18 feet below the surface into the pipe ; in fact it is a vacuum created by the fall of the water.

4483. How is it discharged at the end ?—Into a cistern.

4484. How is the air conducted that is brought down by the water ?—It is drawn through a pipe into the level.

4485. Is the air discharged into a large wooden pipe or soller, or does it merely force its way into the end ?—This is the bottom of the pipe (*describing the same*), the pipe goes out in that direction (*describing the same*), and the water bubbles up over the cistern; the air cannot escape.

4486. Is the air sent along by an air pipe ?—Yes.

4487. To the end of the level ?—Yes.

4488. Then is the smoke from the powder and the candles soon dissipated ?—Yes ; it is soon driven off.

4489. So that the men suffer no inconvenience ?—I should say now that they suffer no inconvenience ; of course there is a little inconvenience felt for five or ten minutes.

4490. Do they resume their work until the smoke has dispersed ?—No ; they stop a little while.

4491. I suppose there are occasions when they rush in at once, or too soon ?—They are not required to do so.

4492. But they do it, do they not ?—Yes ; I am afraid they do.

4493. That is the fault of the men themselves ?—Yes.

4494. Then it is very important that the current of air should be sufficiently strong to drive out the smoke rapidly in order that the men may do more work ?—Yes.

4495. Have any accidents occurred in the last two or three years?—We have been working for 18 years, and we have only had two accidents, no deaths.

4496. From what cause did the accidents occur?—A piece of ground turned out and broke a man's thigh, and in the other case a man blasted a hole upon himself.

4497. In blasting is the powder put into the hole naked, or is it put in in a case?—Generally in a paper case.

4498. Are those cases supplied by you?—Yes.

4499. Are your instructions that it should always be so used?—No; we leave it to the men.

4500. Whether they will use a case or not?—Yes.

4501. Do you not think that a case is safer?—I see no advantage in it in perfectly dry ground.

4502. Then it is merely where the hole bored is in wet ground that you would think it more advisable?—Yes; in damp or wet ground.

4503. In a dry hole you see no advantage?—There is none that I can see.

4504. As far as danger is concerned, is there any danger when a hole is wet in putting in the powder?—No; it is to secure the powder.

4505. Do the men prefer tribute work or tut work?—We have very little tribute work; it is more tut work.

4506. Do you work your mine by means of tut work?—Yes, principally; we have only three or four pitches.

4507. Are the miners upon the whole healthy?—Yes.

4508. Do you know any of them who are now suffering from what is termed miner's disease?—They have colds; there is only one man who is suffering, but he is able to work.

4509. On the surface or underground?—Underground.

4510. Is he able to ascend the ladders?—Yes.

4511. Has he been long suffering to your knowledge?—He has been with us for about five years; he is about 48 years of age, and I suppose that he must have caught cold, or something of that sort in some other mine.

4512. In what way does he suffer?—He has a little tightness at the chest.

4513. And a cough?—Yes.

4514. And difficulty of breathing?—Yes.

4515. And yet he is able, your mine not being a deep one, to ascend the ladders?—Yes; he never complained.

4516. In the other mines which you have stated you have been connected with, were there any ends where there was poor air?—Yes; I think in the two first we must have had ends where there was poor air, but that is more than 30 years since.

4517. Were any other means than those which you have mentioned adopted in those instances?—We forced in air.

4518. By what means did you force in the air?—By working in a box in water.

4519. Can you describe it to the Commissioners?—One box worked in the other; the other box was filled with water with a valve on the top, and every time the box lifted, the valve would lift and shut again, and press in the air; but it is a very inferior way of doing it. A fan is best, worked by hand, or a little water-wheel.

4520. In that case it is merely making the air that is below circulate when it is done by hand?—Yes.

4521. (*Mr. Davey.*) In what mine did you drive a level for 200 fathoms?—At South Crinnis.

4522. Was it the adit level that you drove in?—No, the 35 fathom level below the sea level.

4523. You had, I suppose, communications from the other levels by winzes?—Yes.

4524. Then you did not at a distance of 200 fathoms from the shaft drive the air all the way in there?—Yes, we did; it was a cross cut south.

4525. And you carried out the whole of the 200 fathoms by the use of the soller?—Yes.

4526. Did you find that at all times sufficient to drive the air in?—Yes, quite sufficient, unless it was a very foggy day, and then the mine was generally affected.

4527. I think you stated that you had worked it in East Crinnis?—Yes.

4528. And you stated, I think, that there were other means by which the miners could ascend besides the ladder or the man engine; was that by an inclined plane?—No; I do not think that the miners went up; I think it was too hazardous. I think it was not used, generally speaking.

4529. What objection do you see to the men being drawn up in a skip?—The men do not like to risk themselves under a chain. We do not use chains.

4530. You think that coming up in a kibble would be dangerous?—Yes, there would be the danger of meeting.

4531. How long have you been working in the mines in Cornwall?—For 40 years.

4532. What improvement do you consider has taken place in the condition and health of the miners during that time?—I think that the miners, generally speaking, are supplied with much better air than they were formerly.

4533. Do you think their condition is altogether better?—Yes; I think that they are longer lived, and that they enjoy better health.

4534. Do you recollect in your younger days seeing the miners in their large frieze great coats in the towns sunning themselves when in a state of consumption, and coughing constantly?—I have seen them certainly.

4535. Do you ever see the same thing now?—No.

4536. (*Mr. Fulke Egerton.*) Have you had a great deal of experience in deep mines?—No.

4537. Have you had any experience in them?—I have had experience in mines about 150 fathoms deep.

4538. Are you of opinion that the man engine is an economical mode of working a mine?—Yes.

4539. Is it more economical than the ladders?—Yes, in a very deep mine, where there are a great number of men.

4540. At what depth do you think it advisable to put down a man engine, or can you speak with certainty upon that point?—When we go down below 100 fathoms.

4541. I suppose the principal saving is the saving of time?—Yes, and the men's health.

4542. You have stated that the men object to trusting their lives to a chain. Have you ever seen a pair of ropes in use in the collieries in the north?—Yes.

4543. Do you think the men would have the same objection to them?—Of course you mean that the skip should work in guides?

4544. Yes.—I think the prejudice might be overcome.

4545. In that case should you say that the use of a wire rope similar to those which are in use in the north, to enable the men to ascend, would be as satisfactory to them as the man engine?—I should prefer a man engine.

4546. On the average, what weight is now brought up in the skip?—15 cwt.

4547. Does that include the weight of the skip?—No, without the skip; that would be about a ton or 21 cwt.

4548. (*Mr. Holland.*) You say that you would prefer the man engine to the skip; is that because you think it safer?—Yes.

4549. Is that the only reason?—We do not use wire ropes in this neighbourhood.

4550. If your objection to them was removed then your objection to the skips would be removed?—I think I should prefer the man engine.

4551. For what reason?—I fancy that it is safer.

4552. But should you prefer it for that reason only?—Yes.

4553. If it were proved to you that the other was

ST. AUSTELL. Mr F.Barratt. 22 April 1862.

equally safe, would you then have any objection to it?—Yes.

4554. How long does it take to ascend 100 fathoms at a fair pace by the ladders?—About 20 minutes; that is tolerably easy work.

4555. Those twenty minutes are equal to an hour's labour, are they not?—Yes; about that, I suppose it is.

4556. Then in fact you make a man do nine hours work in eight hours; or, in other words, you impose an additional hour's work upon him by the use of the ladders?—Exactly so.

4557. Would it not therefore be much cheaper to have a skip to raise them up rather than make the men climb up, and by that means undergo an additional hour's labour, or, in other words, would not the value of the hour's work of all the men be very greatly in excess of the cost of working the skip?—I think that the men at present would not take to the skip.

4558. I am asking you to give your opinion; do you not think that it would save the men fatigue?—Yes, certainly.

4559. Is it not the fact that when the man engine was first introduced the men had a very strong objection to it?—I think it was not so in our neighbourhood, but I have heard of such a thing in the west.

4560. Have you not heard the men say, when the man engine was first talked about, they would not go upon it?—No; I have heard the men say at Fowey Consols, that they were very well pleased with it, and that it saved them a great deal of fatigue.

4561. You stated just now that you thought it probable the prejudice against the skip would be removed after a trial?—Yes.

4562. Then you consider it a prejudice?—Yes; I have no doubt of it, in many instances perhaps it may be so.

4563. The men entertain a prejudice without any knowledge?—I am sure that they would not risk their bodies were there was a chain working.

4564. You stated a short time back, that you preferred a fan to a duck engine?—Yes.

4565. Why?—Because it throws the air stronger.

4566. Why does it throw the air stronger?—I mean our duck engines, I do not know what others there are.

4567. A duck engine will throw the air as strongly as a small fan?—We find in practice that the fan is the best; a duck engine as large as this room may throw a great quantity of air.

4568. Is that the only reason why you prefer a fan to a duck engine, because it throws the air stronger?—I think that the fan engine is more easy to work.

4569. For the same quantity of air?—Yes.

4570. Have you calculated that?—Yes, I think we have.

4571. Have you measured it?—We have thrown aside all the duck engines, and have introduced fans, because we find that the fans are the best.

4572. You have not measured what amount of power each works at?—We find that a very small fan will throw in a greater current of air than the other engine of a moderate size.

4573. Have you measured them or compared them?—No.

4574. Those who have measured them have come to the opposite conclusion?—I do not know that.

4575. Is there a regular up-cast and down-cast current in the mine; does the air regularly go down one shaft and regularly come up the other?—No, not regularly.

4576. Is the air in the shaft good?—Yes.

4577. How can that be?—I do not know how it is, but so it is.

4578. Without a regular current up one shaft and down the other, you say that the air in the shaft is good?—I have found this, that the highest shaft is the down-cast.

4579. Regularly?—I have found at times the down-cast shaft 15 or 20 fathoms higher than any other shaft; the mine has a down-cast for about six months outright.

4580. And the longer shaft is a dow-ncast shaft generally, you say?—Yes.

4581. Is it not the contrary?—I will give you a proof of it. The adit there throughout the mine, or at least at that point, was 35 fathoms deep, and I have seen icicles at the adit level in the highest shaft, the shaft being nearly 20 fathoms higher than any other shaft in the mine.

4582. That is to say, it came up to a higher surface?—Yes.

4583. And it was regularly down-cast?—Yes.

4584. To what depth in the mine?—The mine was 100 fathoms deep; 100 fathoms below that level.

4585. About what was the temperature of the bottom level?—I should think about 50° or 60°.

4586. Is that the usual experience, or is it not a remarkable exception?—We find at South Crinnis that the highest shaft is frequently the down-cast shaft.

4587. How is it at the deep mines?—I cannot speak of any more than the Charlestown mines.

4588. When you ventilate an end you drive air into the shaft along the air-pipe, do you not?—We put in sollers now.

4589. When you ventilate artifically with the fan?—Then we put in pipes at the back of the level.

4590. And drive it from the shaft into the end of the level?—Yes.

4591. (*Mr. Austin Bruce.*) Have you ventilated other mines, besides the one which you manage at present, by means of the sollers you have described?—No; by a waterfall.

4592. Were the close ends as well ventilated by means of the waterfall as by means of the sollers?—No.

4593. The men, therefore, in the close ends work under more favourable conditions now than they did formerly in the mines?—Yes.

4594. Do you think that you get more work out of them in consequence?—Of course we do.

4595. Do you make any difference in the price of the labour in consequence?—I dare say that the price is a little less.

4596. And that is to the advantage of the adventurer?—Yes.

4597. While the good air is to the advantage of both?—Yes.

4598. Does this system of ventilating by means of sollers apply to rises as well as to close ends?—Yes.

4599. Do you so apply it?—Yes.

4600. Then the men working in low rises are just as well off as if they were working in any other part of the mine?—Yes; they are tolerably well off.

4601. Why are they not perfectly well off?—In the rises the stuff may fall down and may choke the passage, and therefore the air is obstructed for a short time.

4602. But only for a short time?—Yes; they go down and clear it out again.

4603. Have you not had instances of men working for months in bad air?—No.

4604. Nor for weeks?—No, nor even for days.

4605. Is there any real difficulty in so directing the current of air that there shall be, as there is in coal mines, a regular down-cast and a regular up-cast?—With us, we cannot make sure of the down-cast or up-cast; sometimes the down-cast may be the up-cast, and *vice versâ*.

4606. I know that the fact is so; but what I wish you to explain to the Commissioners is, why it is not possible to do in copper and tin mines what is done in coal mines?—I have seen a large mine that the men could not go down more than two or three fathoms below the surface of a morning in still foggy weather, and yet in the course of six hours that air would be driven away, and the men could resume their work; this, of course, was in a valley.

4607. If you had an up-cast shaft, with an air-pumping engine at its mouth, you would have secured a current of air which would enable the men to go down at any time, would it not?—I think it would be an advantage to have an engine to exhaust the air.

4608. But in that case it would be necessary so to conduct the ventilation that it should not return indiscriminately to every shaft, would it not?—Yes; I think that would be an advantage.

4609. Do you see any reason why that could not be done?—A column of pipes could be put down, and the air could be exhausted by an engine above; but I would rather force the air into the mine.

4610. If you forced the air into the mine you would not keep a distinct up-cast and down-cast in the manner I have suggested would you?—You could force the air into the down-cast and it would come up the up-cast.

4611. If you forced the air down the down-cast might not a portion of the return air return up the very same shaft?—It is possible.

4612. Is not that a thing to be avoided?—Why so, as long as you supply the bottom of the mine with good air?

4613. Is not the object to secure a sufficient quantity of good air to all the workings?—Yes.

4614. And to make the bad air, that is, the air already breathed, pass to the outer air without returning through the workings through which it has already passed?—You could drive the air to the extremity of the mine by an engine forcing in air only, and continue your pipes. I would have branches to the bottom to let out the air.

4615. If you had a regular down-cast shaft, and a regular up-cast shaft you would not require any pipes in the down-cast?—No, if you can make sure of your up-cast and down-cast.

4616. That can be done by proper management can it not?—I do not know; but I see accidents occur, or I hear of them in collieries, where there is no up-cast or down-cast, or no circulation.

4617. But those accidents occur from the accumulation of gases and from an insufficient supply of air do they not?—I should endeavour to drive out the accumulation of the gas, and drive it out to the surface, that is what I mean.

4618. Do you use water power for ventilation?—No.

4619. Have you ever seen it used?—Yes.

4620. Have you seen the system which is adopted by Mr. Williams?—I do not know what it is.

4621. You have had I believe but very few accidents in your mine from the use of powder?—Very few.

4622. But accidents are nevertheless very frequent in the neighbouring mines, are they not?—I think not.

4623. You have stated that, in your opinion, the health of the miners is better than it was, and that they are longer lived?—Yes.

4624. Do you state that from any careful examination of the register of deaths, or from your general observation?—I think that 30 years ago the health of the miners gave way sooner than it does now.

4625. Is that opinion based upon your own general observation or upon such registers as you have examined?—It is based upon my own general observation for 20 or 20 years back.

4626. Do you believe that at present the health of the miners is as good, and their lives as long as those of the non-mining population?—I think that a miner's life is of shorter duration than that of men engaged in other employments.

4627. Shorter than that of agricultural labourers?—Yes.

4628. Why should it be so?—It is from breathing powder smoke which is injurious, there is no doubt of it.

4629. But where the ventilation is as good as yours and the powder smoke soon dispersed, there is no necessity for them to breathe the powder smoke?—With us I think that the miners are just as healthy and live as long as other working people.

4630. But you do not think that they are so in general?—No; not in the deeper mines where they are not so well ventilated.

4631. Is there any reason why the very deep mines should not be as well ventilated as yours are?—I think that there is more difficulty in deep mines than in shallow ones.

4632. But why so?—The current is not so strong at the bottom.

4633. Ought not the current to be rather stronger in deep mines, where there is a greater difference between the temperature of the top and the bottom of the mine than in shallow mines?—We do not find it so in practice, the current is not so strong in deep mines as in shallow ones; I do not know why it is so, but so it is.

4634. In a question affecting the health and the lives of men, wherever difficulties in the natural ventilation occur, ought not artificial means to be resorted to to assist the natural ventilation?—Yes.

4635. And do you know of any case where, by the joint use of artificial and natural ventilation, sufficient air cannot be introduced?—No, I do not.

4636. Do you think that the question of cost would interfere with a sufficient supply of air?—Yes; it may be so.

4637. You have had the advantage of examining coal mines?—No; I have never been underground; but I have seen them at work,

4638. Do not you think that it would be an advantage to the Cornish captains if they were sometimes to see what is going on in the other mining districts of England?—In what way?

4639. In the way of ventilation.—I have never seen any advantage to be derived from that.

4640. Do you think that the Cornish miners have nothing to learn from any other people?—Yes; a great deal.

4641. Then considering the immense difficulties that exist in the ventilation of coal mines above those which exist in the ventilation of copper mines, is it not natural that the ingenuity of man should have introduced some better means of ventilation in coal mines than in copper mines?—I should say, as a whole, that the copper and the tin mines are better ventilated than the coal mines.

4642. What makes you say so?—I know that in some instances there is only one shaft in coal mines, and you cannot get a very good ventilation where there is only one shaft, and where the workings extend for a considerable distance.

4643. Why not?—I do not know why not; but so it is in practice.

4644. Do you suppose, where there is only one shaft, that that shaft is not so completely divided into two, as to separate the down-cast from the up-cast?—I think there would not be a continous current there.

4645. You do not think that anything is to be learnt from the collieries of Durham or Newcastle in the way of ventilation?—I am not exactly sure about that; but I think that copper mines, from what I have heard and read, and tin mines, are as well ventilated as coal mines if not better; that is my view of the case.

4646. Do any of your captains travel out of Cornwall?—Yes; some of them do.

4647. For the purpose of making inquiries?—No.

4648. (*Mr. Kendall.*) What is your opinion about the down-cast and up-cast; as I understand you there is no regular down-cast and up-cast in your own mines?—I have found it to be so in practice.

4649. Did you ever find the want of a draught in a mine where there were two shafts?—Yes; I have.

4650. Was the air dead?—Yes.

4651. For any length of time?—I have known it to be so for a day.

4652. For how many days in a year have you

Sr. Austell. Mr. F. Barratt. 22 April 1862.

known that state of things to exist in your mine ?—I have never known it in winter, but in summer, in very hot weather—dull, heavy weather.

4653. Your supply of air, when you use artificial means, is of course taken from the main draught, that is from shaft to shaft and from level to level ?—Yes.

4654. Are there times when you have no air there to pump in ?—Yes ; and the men cannot go down.

4655. On those occasions the men do not go down ?—They cannot, they have no light ; the candle would be quenched in a moment.

4656. Has that occurred several times within your knowledge ?—Yes, at East Crinnis, and at Pembroke in the valley.

4657. Have you ever heard of that being so in any other mines in the neighbourhood ?—No, I think not.

4658. Speaking generally, where you have a connection by a shaft, have you not generally a good through draught ?—Yes.

4659. Very good ?—Yes.

4660. Does not the candle show you sometimes that it is very strong ?—Yes ; you are scarcely able to keep the candle burning on account of the draught being so strong.

4661. In those exceptional cases the men do not go underground ?—They could not go down.

4662. Do you, or do you not, when you find there is bad ventilation at once resort to artificial means ?—No ; a few hours would remove it, a change of wind would do it.

4663. But I mean generally speaking in the ends ?—Yes, they always adopt means immediately to send in air, either by fans or by bratticing.

4664. Have you ever known instances where, when the men have complained, and the complaint has been well founded, they have remained for three days, or four days, or a week before they have ceased to work ?—No.

4665. You at once attend to it ?—Yes ; the men would be ill otherwise. I never ask the men to work in poor air, I tell them to stop.

4666. I suppose the men do stop before they give you notice ?—Yes ; the tributers would be in a back level, perhaps in poor air.

4667. Comparing the tributor with the tut-work man, which do you think is the longest lifed ?—I should think there is not much difference, I should say they are just the same.

4668. Have you found that the deprivation of light for eight hours has something to do with the health of the men ?—I do not know in what way.

4669. Generally speaking a miner is a paler looking man than an agricultural labourer ?—Yes, he is certainly.

4670. Much paler ?—Yes.

4671. Do not the tributers at times overwork themselves ?—Yes, they do.

4672. For instance, suppose a man takes a pitch at 10*s.* in the pound, does it not frequently happen before the pitch is out that he finds he could work it very well at 2*s.* in the pound ?—Yes.

4673. If his time is short, unless he can have any other help, does he not frequently work 16 hours instead of 8 ?—Yes.

4674. They work like slaves do they not during 16 hours ?—Yes.

4675. Did you ever know a case in which a man who had got a start did not work like a slave, or at all events work very hard ?—I think not.

4676. And in most cases much harder than he ought to work ?—Yes.

4677. And much to the detriment of his frame ?—Yes.

4678. Does not that, in your opinion, tell much against the average life of a miner as compared with an agricultural labourer ?—Yes, no doubt of it.

4679. Now take the converse of that. Suppose that a man has got a fair price and the pitch fails, according to your experience, does he then work harder to make up for it ?—No.

4680. He gets disheartened, does he not ?—Yes.

4681. And it is quite the reverse of the other case ?—Yes.

4682. He often does not work at all ?—It is the hope of reward that sweetens labour.

4683. Is not this the fact that if a pitch turns out better than a miner expects, and he earns more wages, that he labours much more than he ought to do ; and if it turns out worse than he expects he gets disheartened, and he works less than if it proves to be a good pitch ?—Yes, just so.

4684. A good deal has been said about the skip and the man engine ; you have been asked whether the skip is not a more rapid mode of descent, and you said yes ; did you take this into your calculation, that by the skip some five or six men alone can go down, whereas, if you have a man-engine reaching down 240 fathoms you may have 120 men on that same engine at the same time ?—Yes.

4685. Taking that into your consideration, is not a man-engine, as far as economy of time goes, as good as a skip ?—Yes.

4686. You were the first person, I think, who introduced the skip into this neighbourhood ?—Yes.

4687. Was your shaft a straight one ?—Yes.

4688. Suppose you were to go into a mine where the shafts were not straight, and you wanted to apply either the skip or the man-engine, which would be the easiest to introduce, if the shaft were irregular ?—I should say that the man-engine would be the easiest to introduce.

4689. As far as your experience goes, the skip must either have a direct inclined plane to work over or the shaft must be perpendicular ?—Yes.

4690. But with a man-engine you can vary it ?—Yes ; and it is done.

4691. With regard to the food of the miners, you are in the habit of visiting them, I believe, a good deal ?—I see them.

4692. Do they take their principal meals underground, or in the evening when they reach home ?—They bring a small quantity of food with them ; a little pastry ; and they sit down and eat that about 10 or 11 o'clock.

4693. But they take the chief meal, do they not, at home ?—Yes.

4694. Of what does that meal consist, and is it a wholesome one ?—I do not know ; but I should think it would be.

4695. Can you state whether the miners eat much animal food or not ?—Most of them I think get a tolerable quantity of animal food.

4696. You have been speaking of the fan engine and the duck engine. I suppose from what you said, that you have discontinued the use of the old duck engine, which was possibly an inferior one of its kind ?—Yes ; not large enough perhaps.

4697. And you have resorted to the fan ?—Yes.

4698. I suppose you judge of the value of the fan by the burning of the candles in the ends ?—Yes; by the quantity of air that is thrown into an end.

4699. You feel that, and are sensible of it ?—Yes.

4700. What is the comparative amount of labour required for the fan and the duck engine. Could you employ boys to both ?—Yes, to both ; the duck or the fan in the various levels. The duck engine has a cistern, one working in the other.

4701. Is there much difference in the cost of the two ?—The fan would cost about 2*l.* 10*s.*, and the duck, I should think, would cost just the same.

4702. Then what would the labour of working cost ?—There is not much difference.

4703. As far as you have seen, is the effect of the fan much greater than the effect of the other ?—Yes.

4704. What is your opinion as to the comparative utility of exhausting the air, or of forcing it into the shafts so as to have a regular up-cast and down-cast; do you think, taking the mines generally in Cornwall, from what you have heard, that there are five

mines in Cornwall that are at all in the condition that you have stated other mines were, that is to say, with no draught at all, no up-cast nor down-cast, and the air so dead that you could not burn candles ?—I know another mine; Tywardreath mine was in the same situation—that is just below Par Consols.

4705. That is upon a flat ?—Yes ; in a valley.

4706. Where mines are in valleys, it is not at all unlikely that the same thing would occur ?—No.

4707. During several days in a hot summer ?—Yes ; perhaps for two or three days.

4708. In the year ?—Yes.

4709. With the exception of those two or three days in mines situated in valleys, you say that, generally speaking, there is a strong draught throughout a mine ?—Yes ; the circulation would be free.

4710. Quite free, that is, not only for general use, but for giving a supply when you resort to artificial means ?—Yes.

4711. Save and except in the mines which have been mentioned, would it be worth the cost, or would it be any particular service to employ the exhausting engines which have been referred to would it pay ?—I prefer the forcing engines.

4712. Would it pay to employ them ?—I think it would pay for deep mines.

4713. Your view is that in a very deep mine it would better to employ a forcing engine ?—Yes ; it would lessen the temperature in the first place and increase the volume of the air.

4714. And it would also, I suppose, save time with regard to clearing away the powder smoke ?—Yes ; no doubt of it. I would not let that air remain at the very bottom of the shaft ; but have apertures in the pipe, so as to send it through and through and everywhere.

4715. It is a mere matter of opinion as to whether you should exhaust or force in ; your opinion is that it would be not only useful to the men, but also economical for the adventurers, if they were either by exhausting or by force pumps to supply a current of air, not only in the main shaft, but throughout all the levels ?—We tried the exhausting principle at East Crinnis for some years ; we were advised to do so by the principal manager, and we found that we could not drive our levels very far, and we then changed, and introduced the forcing principle, and we found that we could drive a considerable way further.

4716. As I understand you all you require is this : that by some means enough air shall find its way into every end, and you would then let nature take its own course and let the air find its way out ?—I do not care where it goes.

4717. (*Chairman.*) You would send the air down with one pipe, and with branches from that to the different ends ?—I would.

4718. Would that be a very expensive process ?—I think not.

4719. What pipes would you use ?—That would depend upon the extent of the mine, a foot diameter would carry a large volume of air ; it is no new idea of mine ; I have turned it over in my mind for years and years and the result is that I would throw air to the bottom of a mine ; I would not exhaust it. I would throw fresh air from the surface.

4720. (*Mr. Holland.*) And the different levels, connecting one shaft with another, would divide the current ?—Yes ; we put doors in to carry the air through, otherwise the current would be weakened.

4721. You say that the main levels are, as a rule well ventilated ?—Yes.

4722. How long does the powder smoke hang about in the main level ?—From 10 to 15 or 20 minutes, depending upon the strength of the current.

4723. In the main level ?—Yes ; it depends upon how far the main level may be beyond the winze.

4724. If the powder smoke hangs about for 15 minutes do you consider that that is a sign of good ventilation ?—Yes, I should think that tolerable ventilation ; sometimes it hangs about for five minutes only, and sometimes for not more than a minute.

4725. The same shaft seems sometimes to be an up-cast, and sometimes a down-cast ?—Yes.

4726. Are the variations rapid on a gusty day ?—Yes ; I have known them to change momentarily.

4727. Perhaps several times in an hour on a gusty day ?—Yes ; I think I have known that.

4728. When a change takes place and when an up-cast shaft becomes a down-cast shaft, does not the air that has just left a mine enter it again ?—I suppose it does.

4729. Is it not exceedingly important in order to keep a mine pure that the same shaft should be an up-cast shaft always ?—Yes ; but that is rarely the case.

4730. Is it not commonly the case that the draughts are fighting in the up-cast shaft ?—Not commonly.

4731. Are you sure of that ?—Yes, I think I am sure of it ; it may occur.

4732. In those mines which you consider are well ventilated do the candles always burn well ?—Yes.

4733. Are they never obliged to slope them ?—No ; not in good air mines.

4734. If it has been stated that the men are often obliged to slope their candles to keep them alight, is that a correct statement ?—No ; there are some mines in which they are obliged to do it where the air is so weak and so foul too.

4735. But that is not the case in your mines ?—No ; there is as good air in our mines as there is in this room, just as good for the men to work in.

4736. And yet in those places where the air is so good the powder smoke will hang about for 15 minutes ?—Not there, but in some of the ends.

4737. I am speaking of the levels ?—Yes ; and so am I ; but the end of a level may be 20 or 30 or 40 fathoms beyond the last winze, and it will take a little time for the smoke to come out and to go up.

4738. It would not take so long if there was a strong draught ?—No ; if there was a pumping machine to pump in air it would be out in a very short time.

4739. You have stated that the man-engine is better adapted than the skip for a shaft when it is partly vertical and partly on an incline ?—Yes ; I think so.

4740. If it should be found that a skip will work well in a shaft that is partly vertical and partly inclined, your objection to the skip would be removed, would it not ?—I think the men would prefer it, as far as I have seen them.

4741. But what would you prefer ?—I should prefer the man engine.

4742. Would not the last objection that you have mentioned to the skip be removed, if it were found that the skip would work well in a shaft that was partly vertical and partly inclined ?—The skip must travel on the underlie as well as upon the perpendicular, and I think it is more liable to get out of repair than a man engine.

4743. But suppose it worked for two years, and did not get out of repair ?—Then my objection would certainly be removed; but I have not seen that.

4744. (*Chairman.*) Although there may be a strong draught in your mines with many shafts, are there no ends in which the air is poor ?—Yes. I suppose in some deep mines that the heat is so unpleasant either from the weather or from the ground, perhaps from both, as that really the air is difficult to breathe.

4745. And yet notwithstanding in parts of the mine the current is so strong as to blow out a candle?—No, not the current there.

4746. But in other parts of the same mine ?—Yes.

4747. Have complaints often been made to you of the poor air ?—No.

4748. Do you know that the men do complain sometimes of poor air ?—Yes ; I have known them complain some 20 or 30 years ago.

St. Austell.

Mr. F. Barratt.

22 April 1862.

4749. Do they not now complain within your knowledge?—No; they say that the air is rather dead, and we take steps to improve it.

4750. But in driving an end in a new mine to reach a shaft, it is necessary is it not to work in that end where the air is poor?—Yes; but we either put in sollers at once, or a fan machine, or a water-fall.

4751. But if neither of those things is done what is the consequence?—Then the air would be bad.

4752. Are there air machines in every mine?—I cannot say that.

4753. Would not a tut-work man persevere in working in poor air, where he felt that his means of supporting his family depended upon his exertions?—I suppose he would.

4754. So that both the tribute man and the tut-work man may be induced to work beyond their strength, or else under unfavourable circumstances, because it is necessary to provide the means of supporting their families?—Yes, I dare say it would be so.

4755. You say that the health of the miners has improved during the last 30 years; has it improved during the last 20 years?—Yes.

4756. Has it improved in the last ten years?—Yes.

4757. Do you know at all the ages of any of the men who are working in your mine at the present time?—Yes; we have a few as old as 64 and 65.

4758. And have those men no apparent ailment?—They are, generally speaking, healthy men.

4759. How long have any of those men worked in your mine?—Perhaps the oldest for about four or five years; he might have got complaints in other mines before he came to ours.

4760. Has no man worked in your mines more than four or five years?—Yes, some have worked there for 10 years. I think a man of the name of John Stephens is 64 or 65 years of age.

4761. Could you, if necessary, give the names of a number of men who have worked in your mines for 10 years?—Yes; I think I could from the books.

4762. (*Mr. Kendall.*) You have been asked about the tut-work men working in poor air to maintain their families. Would the agents allow a man to work in poor air for any length of time if they were aware of it?—No, I should think not; it is not economy to let men work in poor air; the adventurers lose money by it, for the men cannot do so much work.

4763. But still there are cases, are there not, where the men do work on under such circumstances?—Yes; but that will depend upon the price.

4764. Do you think that a man would be afraid to complain of bad air for fear he might be thought to be a troublesome fellow, so that he would work on and suffer thereby?—So far as I am concerned I invite the men to do it.

4765. I have no doubt of that, but the object of this Commission is to get at the bottom of everything that takes place in mines; do you think that there are mine agents who might perhaps be rather careless upon these points?—It is possible.

4766. (*Mr. Holland.*) Do you think that that is common?—I do not know, but I should hope not; the men themselves can tell you best.

4767. (*Chairman.*) Do you think that the men would not be afraid to speak out if they were examined by the Commissioners?—I should hope not.

4768. Do you think that the men would come here willingly to be examined?—I should think so.

The witness withdrew.

Mr. Francis Puckie, examined.

Mr. F. Puckie.

4769. (*Mr. Kendall.*) You are chief agent under the Reverend Mr. Treffry and his co adventurers?—Yes.

4770. In what mines?—In Fowey Consols, Par Consols, West Fowey Consols, Prideaux, and East Crinnis.

4771. How many working miners have you under your charge?—In all the mines, I should say very nearly 2,000.

4772. How many of those work underground?—I should say more than 1,000 work underground.

4773. You experience has been very great?—Yes; all my days.

4774. When did you begin?—At nine years of age.

4775. At what wages did you begin?—At 5*s.* a month, hardly 2½*d.* a day.

4776. Then you have gone through all the gradations, and worked both at tribute, and at tut-work?—Yes.

4777. And as grassman?—Yes; I began from the owest grade of mining, that is the trunking boy.

4778. You are acquainted with all the operations?—Yes; I have gone through all of them.

4779. What age are you now?—51.

4780. Have you brought with you a plan of the Fowey Consols mine?—Yes.

4781. How long did you work at the Fowey Consols mine?—I went to work in the Fowey Consols in the year 1826. I was born in the year 1811.

4782. You worked there as a miner until what year?—Until the year 1836.

4783. And during all that time you worked there as a miner?—Yes.

4784. How deep was the Fowey Consols mine when you left, at the deepest level?—I am not prepared to say exactly.

4785. But about how deep was it?—I know that the richest part of the mine was about 120 fathoms deep, and I believe she was then at 140 or 150; I may remark that when I left Fowey Consols in 1836 I went down under Mr. Treffry, the little mine at St. Stephens; I was there till the year 1842 under him, and then I came from there to Par Consols.

4786. And have you been there ever since?—Yes.

4787. How deep is Fowey Consols now?—800 fathoms below the adit, which is 40 fathoms.

4788. Then that at present is the deepest?—Yes; that is the deepest part of the mine.

4789. Do you think, if there was not a man engine there the men could work in those deep levels?—No; I do not believe that we should have any one to work there, but for the man engine.

4790. Unless you had a man engine, no man would work there?—No.

4791. Do you consider the man engine to be useful to the men as far as their labour is concerned?—Yes.

4792. Have you observed that a great improvement has taken place in the men's health in consequence?—Yes; it has been one of the greatest reliefs that ever the miners had.

4793. You go down to the very bottom of the mine at Fowey Consols do you not?—Yes.

4794. You inspect every level there?—Yes; I inspect every level that is working; we are working at the 270, that is the deepest level that we are working at the present time.

4795. You mean under the adit?—Yes; we work at that now.

4796. That is 310 fathoms deep?—Yes.

4797. What number of men are working at the 270 fathoms?—There would be one pair of men there—six men.

4798. Would they work there 8 hours a day?—Yes.

4799. Is the 270 laid down upon the plan you have produced?—I believe so; but it is not our regular working plan; it is a mere copy of it.

4800. How far is the end of the 270 fathom level from any shaft?—Very near 200 fathoms.

4801. The air in the end at the 270 level is supplied from a shaft which is 200 fathoms distant ?—Yes.

4802. How is it supplied ?—By winzes, sinking from one level to the other.

4803. You have got levels at the 260 and the 270, driving on in the same direction ?—Yes.

4804. And at every 20 fathoms or so is there a winze ?—Yes, or 30 fathoms ; we sink a winze to ventilate the ends, and likewise to open the ground for the tributors.

4805. How far is the end of the 270 fathom level from your last winze ?—About 20 fathoms.

4806. How far is the end of the 260 fathom level behind the 270 ?—About 20 fathoms more.

4807. Behind ?—Yes ; and as soon as we can get through this cross course (*pointing to the plan*) we shall drain the lode of the 260, and then we shall commence sinking a winze to ventilate 270 again.

4808. Before you begin to sink your winzes I suppose the ventilation begins to fail a little ?—Yes ; of course the place gets close, and sometimes we are obliged to get a machine to blow air in.

4809. After you find the air begin to fail, if you are near holing, I suppose you proceed without any machine ?—Yes.

4810. Have you now got to the point where you have your ventilation ?—Yes ; that is the very thing we want.

4811. Is that what you call not a good end ?—No.

4812. It is not a bad end nor a good one ?—No ; it is warm, the air is very warm.

4813. How will the candles burn ?—They burn pretty well.

4814. But you want better air ?—Yes ; and as soon as we ventilate it will destroy the heat.

4815. At the depth of 270 fathoms, the moment you ventilate does the place become cold ?—Very moderately so indeed.

4816. Is there much difference between that and the air above ?—Very little ; it is almost as cold at the bottom.

4817. As soon as the natural ventilation begins to operate, there is very little difference between the temperature at the top and 300 fathoms below the surface ?—Very little.

4818. Do you judge of that merely by your own sensations, or have you tried it by any means ?—No ; I have never tried it since I have been at the mines.

4819. Has it ever been tried ?—No ; I cannot speak to that. I believe it was tried in the late chief agent's day.

4820. Have you used any artificial means to throw in air at the end of the 270 fathom level ?—No.

4821. Shall you delay doing that much longer ?—No ; we shall be obliged to do it by and bye ; we shall put a machine there.

4822. How do you judge when it is time to have recourse to artificial means ?—When we come to get the air bad the candles refuse to burn ; and at other times when we go in it is so hot, and the powder smoke lies there; that we use artificial means to bring in air to destroy the heat and destroy the powder smoke.

4823. At present you can work on ; but you see that it is time to be looking forward ?—Yes.

4824. Do the candles begin to burn dim ?—No ; they burn very freely.

4825. Can you give the Commissioners any idea as to how many miles of draught you have underground ?—I am sure I cannot say.

4826. Have you ever heard it stated ?—No ; I do not think I ever did hear it.

4827. Have you ever heard that there is as much as 40 miles of railway underground ?—Yes ; I think I did hear that there was as much as 40 miles of railway in Fowey Consols at one time ; we have not that underground now.

4828. The mine not being in such full operation at the present time as it was some time ago ?—No.

4829. Supposing that it was in full operation, taking into account all the levels, most of which you know, in how many ends in the whole of the mine do you fancy there would be what you call bad air, or not very good air ?—There are many places in which there is bad air.

4830. Supposing you were to put men to work in all the different ends, there would be many in which there would be bad air ?—Yes ; but it is more from the poverty of the vein than from the poverty of the air.

4831. If those veins should continue, should you adopt artificial means ?—Yes ; and no doubt there was artificial means to supply air there before the ends were stopped.

4832. How many ends have you got in Fowey Consols now where you ought to resort to artificial means of ventilation, or where you are about to use artificial means ?—We have three or four.

4833. In which the candles now do not burn freely ?—Yes ; where we use artificial means.

4834. How many ends are there now in Fowey Consols where the candles do not burn freely ?—I do not know but of two.

4835. Which are those ?—One is the 180 south, and then the new shaft ; there we are now going to to give orders as we did last year to get pipes to put in.

4836. How far is that from any ventilation ?—I should say 100 fathoms, or very nearly so.

4837. Is there no artificial ventilation there now ?—No.

4838. Do the candles burn dead there ?—No ; they burn very freely. The chief object in introducing ventilation there by artificial means is because we will not put another pair of men to work there ; we consider the air is hardly sufficient to supply two pairs of men

4839. Of how many men does a pair consist ?—Of six men ; we want to put 10 or 12.

4840. Is the heat very great there ?—No ; it is moderate.

4841. If you were to continue there the same number of men as there are now, do you think there would be air enough ?—We could go for a great many fathoms further.

4842. Would not that be a long distance to go ?—Yes ; but there is a great deal of difference, the level is very large.

4843. How high is it ?—I should suppose it is seven feet high.

4844. What is the usual height of a level ?—Six feet high is what we call our usual levels, and four feet wide.

4845. Do you know how many ends you are working in Fowey Consols ?—Not many ends at the present time ; we have not more, I suppose, than about 10.

4846. Working ?—Yes.

4847. For how many of those do you use artificial means to throw in air ?—I think we have not but two now.

4848. Do you think that any more are required ?—The only thing is where we are going to put artificial means on to the 180, and we shall very likely put it on to the 270 ; all the other ends are very well ventilated.

4849. Is that because you actually want air now, or because you think you shortly shall want it ?—Not immediately ; but we shall want air there.

4850. (*Chairman.*) Where do you say those two ends are ?—At the 180 south and the 270 east.

4851. (*Mr. Kendall.*) You can speak more confidently about the different ends at Par Consols than at Fowey Consols ?—Yes ; I have seen every inch of the ground that has been opened.

4852. How many ends have you at work in Par Consols ?—I suppose more than 20.

4853. How many ends in Par Consols are you working by means of artificial ventilation ?—I believe there are five that we work by artificial means ; but then those artificial means will be thrown away again

by and bye as soon as we can hole the winzes, and likewise there are some in driving cross cuts.

4854. (*Chairman.*) You mean by artificial means the boy and the fan ?—Yes.

4855. No other artificial means ?—We throw it in by the force of water.

4856. In any of those ends ?—Yes ; not in the Fowey Consols, in the Par Consols.

4857. (*Mr. Kendall.*) How many engines are you driving in Par Consols ?—I should say more than 10; but I am not prepared to say exactly.

4858. Without artificial means ?—Yes.

4859. You have about 15 ends without artificial means of ventilation ?—Yes, I think so.

4860. What is the deepest level at which you are working an end without artificial means ?—200 fathoms, at Par Consols.

4861. You are not working with artificial means there ?—No.

4862. How far off is that from any shaft ?—I suppose that the farthest end may be 100 fathoms from any shaft.

4863. How far down does the man engine go ?—The man engine shaft is sunk down below the 200.

4864. If the Commissioners visit the mine to-morrow will they be able to see that end ?—We go by the man engine below 165.

4865. Take the next deepest level upwards, the 180 ; how far is that from any shaft ?—I suppose that is 40 fathoms from any winze ; but there we have artificial means by a waterfall.

4866. Then come above that again ?—The 165 is the next.

4867. I mean where you have an end that is being driven without artificial means of ventilation being used ?—Yes ; that is at 165.

4868. How far in is it ?—I suppose 30 fathoms.

4869. From any winze ?—Yes.

4870. How is ventilation effected there ?—There we are sinking a winze to ventilate.

4871. What sort of air is there there ?—It is rather close.

4872. (*Mr. Austin Bruce.*) Is that the closest of all your ends ?—I believe it is almost as close as any we have got.

4873. (*Mr. Kendall.*) What other end is there that is nearly in the same condition ?—We have a cross cut at 120 ; and there we have a fan machine.

4874. How many ends have you like that ?—I believe that that is about the worst we have got, the 165.

4875. Are there any others nearly as bad ?—We may have one or two close places.

4876. Which are they ?—The 100 is rather a close place ; but there we have a machine put in.

4877. I mean where you do not use a machine ?—I do not know of any one that is close beside that.

4878. When the miners find these places close, do you put in a machine ?—Yes ; as soon as we find that the men cannot labour as they ought to do, we use other means to bring air to them.

4879. Do the men ever complain of bad ventilation in your mines without your at once endeavouring to remedy it ?—No, never ; sometimes of course they will complain before they have any need to complain.

4880. Is that when they have made a bad bargain ?—Yes ; or if they want to come up sooner they will plead an excuse, saying that the smoke is bad, or anything of that kind.

4881. (*Chairman.*) What kind of ore does the Fowey Consols mine produce ?—Copper ore.

4882. Is there much mundic in it ?—Yes, sometimes.

4883. Much ?—Not a large quantity.

4884. Is there as much as a fourth ?—No, I should think not, not so much as that ; but I cannot say.

4885. Is these much mundic in Par Consols ?—Not so much as in Fowey Consols. Some lodes do produce more mundic than others ; and some places produce more mundic than others ; there are bunches of ore with scarcely any mundic in them, and some with a very great deal.

4886. How many men are working underground in Fowey Consols ?—I think very nearly 400.

4887. How many in Par Consols ?—There are 250.

4888. How many boys are employed underground in Fowey Consols ?—I cannot say.

4889. How many boys are there in Par Consols working underground ?—I do not know that. I should say that we have 200 boys and girls working at the surface.

4890. Do you know the age of the youngest who is working underground ?—No ; I do not know ; but I should say about 12 years of age.

4891. Do they go down to work with their relations ?—Yes ; perhaps father and son.

4892. Do you think there are none working underground below the age of 12 ?—I cannot say that there is not; but I should calculate 12 years to be about the youngest.

4893. Are there none, to your knowledge, under the age of 12 working underground ?—No.

4894. What is the highest temperature in which the men are working in Fowey Consols ?—I do not know ; we have never tried it.

4895. Nor in Par Consols ?—No ; that is not so high as Fowey Consols ; in some places they are very warm ; perhaps some may be between 70° and 80° in Fowey Consols.

4896. Do you know how long the man can work in that hot level in Fowey Consols? —No ; they calculate that they work there eight hours ; but in those hot places they do not work, perhaps, more than about six.

4897. Are there other captains who act under you in the mines ?—Yes.

4898. Probably they could answer questions better than you can with regard to Fowey Consols ?—Yes, very much better, as they are constantly in the mine.

4899. You stated just now that in driving a level, if you are near to an end, where you put in a winze, you endeavour to proceed, and do not stop the work although the air is bad ?—No ; not if we possibly can keep them working ; and particularly if it is a place of importance ; but we use every means to supply air to enable the men to work.

4900. I suppose that in those instances the men are obliged sometimes to work where the candles burn dimly ?—Yes.

4901. For how long would the men probably work there; a month ?—They may sometimes work there a month.

4902. Or for two months ?—I do not know that exactly ; but there is a great deal of difference at times, and it will depend a good deal upon the atmosphere at the surface ; some days we may have in certain ends as good air as the men need work in, then upon a change of wind at the surface perhaps you may go down the next day, and you cannot carry a candle into the end.

4903. When that is so, do the men come up again ?—Yes.

4904. They must then stop work until the wind changes ?— We generally employ them somewhere else.

4905. But if you have no other work for them they must stop ?—Yes, certainly.

4906. And they do not, I believe, get paid all the same ?—No.

4907. How long have you known a man out of work under such circumstances ?—Perhaps not two days.

4908. And he does not get paid as if he were at work ?—No ; they are always on tut work or on tribute work.

4909. You have stated that as soon as you can ventilate a place the heat is diminished ?—Yes ; as soon as we can get in ventilation that destroys the heat, we get then a current of air.

4910. That is to say when you put a winze in ?—Yes ; then we go on again as fresh as ever.

4911. But until that is done, must not the men work in a close place?—Yes.

4912. Do you judge of how long the men can work by the candles, or in what way?—The men can tell that by their working, and sometimes at the end of a corps the air may get thicker than at other times, and then they may blast a hole just before they leave perhaps, then they will go up.

4913. I suppose the men will endeavour to work on as long as they can?—Yes; the more they work they more they get.

4914. Although the air is bad, yet they will endeavour to work on?—Yes; some will work very much longer than others.

4915. I suppose that a young miner who has not suffered at all in his health will work longer than a man who has suffered?—I do not think there is much difference; some of the older ones will persevere even more than the younger men.

4916. In poor air?—Yes; but I suppose that our mines are as well ventilated as any mines in the county; still we have on certain occasions bad ends.

4917. In these ends where the powder smoke hangs about are the men able to work on soon after they have blasted?—Sometimes they are obliged to stop half an hour after they have blasted a hole, sometimes a little longer, and sometimes perhaps not quite so much; in some places, perhaps, they may not stop scarcely at all.

4918. I suppose that is where there is a current of air?—Yes.

4919. Where there is not a current of air, or ventilation, they have to stop half an hour?—Yes.

4920. In Fowey Consols do you find granite or killas?—Killas.

4921. How many holes can a man blast in eight hours?—That all depends upon the hardness of the ground.

4922. Suppose it is killas?—Then some will blast three, some four, and some not more than two; it will depend entirely upon the nature of the ground.

4923. Are they able to bore two sets of holes in eight hours?—Yes; and sometimes they will bore four.

4924. In how many ends in Fowey Consols is there a fan engine?—Only one; we have got in one end in particular a piston machine that works with an engine.

4925. At one end?—Yes.

4926. Which shaft is that near?—Near the engine shaft, that is where the pumping engine is, and that engine works the piston machine.

4927. Does it supply a greater quantity of air?—No; I would as soon have a good fan as a piston machine, only it is a longer distance to this end, as I suppose 40 fathoms, behind any ventilation, and yet this end has air 50 fathoms beyond where the ventilation is on account of the means of applying the engine.

4928. You have stated that some men have complained of the smoke lying dead; is the captain the judge of whether the end is in a bad state or not?—We all know that when we go into the place.

4929. But when the men complain that an end is bad, is it for the captain to judge of that?—Yes.

4930. When the fan engine is required, does it depend upon whether the captain says it shall be put in or not?—Yes; if he thinks it is necessary to do it.

4931. I suppose you would put it in if the wind changes?—Yes; in places where we have fans working; there are occasions, for instance, we have one place in Par Consols, where, in certain winds, we cannot carry a light, and the reason of that is that the damp settles at the time the men are absent, and they are obliged to force it out again by artificial means.

4932. You force out that damp air by artificial means?—Yes.

4933. There are damp ends?—Yes, there are occasionally.

4934. How do you judge of a damp end?—If you go to a place where the damp is, the candle will go out just as soon as if you put it into a tub of water. I have seen it in our mines where they have not been more than three feet, at the back of a level, and a strong current will go through, and if you put up a candle, it will go out immediately.

4935. Besides poor air, you have to contend with damp?—Yes.

4936. In that damp, have the men ever fainted and fallen down senseless within your knowledge?—Yes, I have known that.

4937. A miner can work for a time in poor air?—Yes; but in the other he could not live in it.

4938. (*Mr. Austin Bruce.*) Is not that called cold damp?—Yes.

4939. (*Chairman.*) In an old mine that has been abandoned, and then worked again, does this occur more frequently?—I do not know, perhaps it may. I will not say that it does.

4940. Does the damp gather at the top or at the bottom of a level?—It is generally found above, more so than below; it is possible to have it in both places.

4941. Have you heard any explanation as to what it arises from?—I do not know what it does arise from. I cannot account for it.

4942. Does it occur in Fowey Consols or in Par Consols?—I have seen it in both.

4943. At what level, or what is the lowest level at which you have known it?—We have it generally more so in the shallow levels in Par Consols than in the deeper ones; we have seen it at the 30 fathom level, and we have had it at the 80 fathom level. I I have seen it in Par Consols, so that you could not carry a candle, not near the end within two feet, and that was just particularly once on coming upon a bunch of ore, and the men came up from underground one afternoon very near the ventilation, and said that the air was so bad they could not keep the candle alight. I said it was impossible as they were so near the ventilation, and they said that they never saw such a thing in the end before. I went down the next day, and I found that the men were correct; you could stand back three feet from the end, and you could see it as well as I can see anything in this room, but you could not carry a candle, not for two or three days there.

4944. The candle would go out?—Yes; after a while it subsided, it went off, and the men worked on as usual.

4945. Were any means taken to get rid of it?—No, it was not required. It went off again, and the men could work on as well as ever. The only way to account for it is by supposing compressed air to be coming out of the lode that has been made a little more porous than others, and it might come out through those pores to escape.

4946. Do you use air sollers at all?—No, we use them very little in our mines.

4947. How many changing houses have you at Fowey Consols?—I suppose that we have got three regular changing houses; but I think the men change in more than 20 houses.

4948. You say that you have three regular changing houses; will you describe to the Commissioners what those are; in the first place, is there a fire kept in them?—We have got in some of them a warm iron tube that goes from a place that we keep always heated to dry their clothes, and to warm the room; every man can change there if he likes, but there are some who would rather change off from those places.

4949. How high are those changing places?—As high as this room.

4950. Are the walls of the changing houses at Fowey Consols as high as those in this room?—Perhaps not quite so high.

4951. Are they six feet high?—Yes.

4952. Are they eight feet high?—More than 10

St. Austell.

Mr. F. Puckie.

22 April 1862.

feet high I should think, some of them; some of them are not quite so high, some are not more than six.

4953. Is there glass in the roof, or how are they lighted?—They are generally lighted by the doors and windows; in some places we have glass lights, and in some places only wooden shutters.

4954. Where there are wooden shutters there would be no light, except by opening the shutters?—Not in some of them, and the doors.

4955. In such a place as that would not the men have to change in a draught?—No.

4956. Do the men never complain?—No. I have very seldom heard any complaint against them. I believe that the men are generally very well satisfied with the changing places, and with the drying of their clothes, and everything of that kind.

4957. Do you not think that it would be an advantage to have a changing house near the footway?—Ours are not very far from it; it is impossible that you can get them near the footway every where without great inconvenience. In mines where they have not the advantage of a man engine of course they have to come up a great distance from the different parts of the mine; in Fowey Consols the men in the mine do not go up and down by the man engine, it is not so far down for them to go underground, they would rather take the ladders in shallow levels; perhaps they would change in the places that were first erected for them, instead of going to the regular changing houses. In Par Consols, in the western part of the mine, we have no man engine, we have different footways and different shafts.

4958. Do the men change in the nearest changing house to the footway?—Yes.

4959. I suppose they do not like to go on a cold wet day a long distance?—No.

4960. Those men who come up by the ladders, come up, do they not, much hotter than those who come up by the man engine?—Yes, very much so.

4961. Do they never catch cold from changing their clothes in a changing house without windows?—I do not think that they do, they are there only a few minutes, and they are gone.

4962. They have to change their clothes?—Yes, they must do that.

4963. Do they wash themselves when they come up?—Yes, almost every one of them.

4964. Where is that done?—Generally in all our changing houses we have the means of bringing the condensing water, which is warm for them, so that they all have the advantage of that.

4965. Do they have the advantage of that in all of them?—No, not in the little ones, but in the principal changing houses they get it.

4966. Is there not a great deal of dust flying about when they change their clothes?—There is sometimes more dust than there need be, because they will get playing one with another, and get throwing about their clothes.

4967. Still their clothes are full of dust, are they not?—Yes.

4968. How many men would change their clothes in one house?—Perhaps we might have 200.

4969. All of them changing in one house?—Yes; but not at one time.

4970. How many should you say would be changing their clothes at one time?—Sometimes as many as 50.

4971. Fifty men changing their dusty clothes would create a good deal of dust, would they not?—Yes, they would sometimes; generally before they go to change, if the clothes are dusty from working in a dirty place, they will go out and clean their clothes before they change them.

4972. But if it were raining they could not do that?—They generally do that; they give them a good shaking, and some of them will take a stick and beat their clothes with it.

4973. Are the women who work above ground all under cover?—Not all, but a great part of them.

4974. Are there some places where they are working without any cover or shelter?—Yes, they could not have it.

4975. But are there places which might be covered in, and which are not covered in?—Yes. In most of our places we have sheds for them, when we can conveniently put them up; and sometimes they are working here at one minute and away at another place at another minute.

4976. Where they sit down are they under cover?—Yes, chiefly; but not all of them.

4977. Is it not desirable that they should work under cover?—It is very necessary in winter time.

4978. And in bad weather?—Yes.

4979. Is there any place for them to go to, to take their dinner and tea?—They have got their places to go to at dinner time or in very wet weather; we have got places on purpose for them.

4980. Separate from the men?—Yes.

4981. Are all the men's clothes dried in those drying houses, or are any dried on the boiler?—Men are kept there night and day to dry their clothes.

4982. Do they dry their clothes as they come in?—Yes, they are all hung up. A miner will say to the man looking after them, "I shall be glad if you will dry my clothes," and he does so.

4983. Is it his duty to do so, unless he is asked?—Yes; but of course he does not know which is wet and which is dry unless he is told of it.

4984. Do you use many doors in the mine in order to regulate the current?—Yes, there are several in different places.

4985. Under whose charge are those?—Of course under the agents, they give the direction, and then of course it comes to the men. We have men on purpose to look after that work.

4986. Is any inconvenience felt from the candles and the powder smoke?—There may be a little in the close places; in the closer places they may feel the effects of them.

4987. Do you contract for the candles, or how are they supplied?—We contract for them.

4988. Do you ever get any bad ones sent in?—Yes, occasionally; but then I do not think we can complain much of our candles.

4989. What would you call a bad candle?—The first complaint is that the grease is so soft, but we have very seldom any complaint as to the candle smoke or anything of that kind. If it is very warm in same places, the grease about the candle gets soft, and they cannot use the clay about them so well.

4990. Do the men judge of the time they should come up by the candles?—Yes, that is the only thing they have to go by, some may carry a watch, but that is a very rare occurrence.

4991. I suppose watches would be spoiled underground?—They do not like to carry them under ground.

4992. In those shafts where they still use the ladders, may the tut-work men come up at any time, or are they fined if they come up shortly before the time?—There is a regular time allowed for them to come up.

4993. Are they fined if they come up before the time?—Sometimes they come up too soon.

4994. Do they wait below until it is time to come up?—Some do, and perhaps some do not, we are disposed to think that some wait on the ladders.

4995. If they stand on the ladders waiting, will they catch cold?—They will certainly.

4996. After they have fired a shot how long do they remain absent?—Some may stop away half an hour, some less, and some longer.

4997. I suppose with the man engine at work at regular times, it is far better for them to come up by that means?—Yes; it works at certain hours.

4998. How long does it work?—It works always on the change of the corps at six in the morning, at two in the afternoon, and at 10 o'clock at night.

4999. For how long at a time does it work?—Generally for an hour and a half or two hours at a time.

5000. At each time?—Yes; it depends entirely upon the number of men to come up; after they are all up, we may as well stop as work.

5001. Do you employ any signal?—Yes.

5002. How do the tut-work men manage to come up?—The tributors come up at a different time, the tut-work men go down at six in the morning and the tributors go down at eight o'clock in the morning, the tut-work men leave again at two o'clock, and we work again for the tributors at 5 o'clock.

5003. Have any accidents occurred with the man engine?—Nothing serious.

5004. What was the nature of the accident that occurred?—We had an accident at Par Consols just after we went to work, through a man's carelessness.

5005. In what way?—I believe he missed his footing.

5006. In stepping on to the engine or on to the plat?—On to the plat.

5007. What then happened to him?—Nothing more than that he came in contact with the soller and injured his chest a little, but it did not detain him only a little time from his work

5008. Were the men at first prejudiced against the man engine?—No.

5009. Did they take to it at once?—Yes; after they had been once on it.

5010. Before that, was there any prejudice entertained by the men against it?—Some of them felt a little timid, perhaps, the first time they went upon the man engine.

5011. Was there any great objection made to it?—No; I do not know that there was.

5012. What other accidents have happened in your mine?—The greatest number of accidents that we have had have arisen from powder explosions.

5013. Do the men put the powder into the holes in cases?—Some do and some do not.

5014. Is it left to the judgment of the men alone?—Yes.

5015. Do you supply cases for the purpose?—Yes; if the men choose to use them.

5016. Are they charged for?—Yes.

5017. What is charged for them?—I think it is something like 1½*d.* each.

5018. Do you think that prevents them from using them?—I have no doubt it does in some measure; then others again do not like them, they would rather shoot with the raw powder; they consider that the cases take up too much room, and they would rather have the powder contained in the hole without anything.

5019. According to the size of the hole they think that they can get more powder in?—Yes; or that they can regulate the charges as they calculate upon the burthen of the ore.

5020. So that in order to get the same explosive force from the powder, they must make the hole somewhat larger?—Yes; the bag may be a little too large and sometimes a little too small for a hole, and many of our men instead of using the prepared cases will make bags themselves for the powder; they would even rather have them that way than have those prepared cases, as they do not come so expensive as the others.

5021. How do the accidents generally happen?—They happen in the tamping, that is after the powder is put into the hole it is filled up with the small stuff, killas generally; we never calculate to put spar for tamping, for it is very fiery and very sharp, and apt to cut the fuze; we generally tamp with killas.

5022. Suppose the men are working, are they supplied with anything to put in?—No, they go back and choose their own material for tamping.

5023. If they take the wrong material it is attended with more danger?—Yes.

5024. How does an accident happen from tamping;—It is generally from the first portion which they put in on the powder that is generally the worst time for an explosion; some of them are not careful enough, and at other times these explosions occur through the men's neglect after they have got the powder in a hole; a very careful man almost always puts in dry sludge, which is as fine as flour, they will put it in upon the powder, and will ram it in with a pud, then they will take the end of this pud and put it in the water-pipe, and hole out all the powder from the hole, and in doing that there is scarcely any danger; but often again they are careless, and they will even put the powder in the hole and ram it down with an iron bar, and then, perhaps after they have put in the powder, and they come to put in their first portion, they are not careful in cleaning out the hole, they will ram away and perhaps make fire in the hole which will ignite the powder; that is the only way in which we can account for those explosions.

5025. Do your men use steel borers?—Yes.

5026. Do they use them to ram down with?—We never use them for ramming; we use a steel borer to bore a hole.

5027. Did you not say that the men used a borer and rammed with it?—No; that is the tamping bar.

5028. Is that made of wood?—No, the tamping bar is of iron, but we have always a swabstick to clean out the hole with.

5029. Do you think that accidents occur from not cleaning out the hole?—Yes.

5030. And not putting in the proper material?—Yes; perhaps too fiery a material for the tamping.

5031. In ramming it down a spark may be made?—Yes; it is just the same as rubbing a piece of iron over spar stone, you will see fire follow from it.

5032. In ramming it down, why should not the stuff be put together?—It would not tamp tight enough, it has to be rammed as tight as the rock itself.

5033. Is there any material that they could use for tamping that would not strike fire?—I do not know, we always tamp with iron.

5034. Have you ever heard of a composition of metal that would not strike fire?—We have never had it, nor used it.

5035. Do the men use a wooden mallet?—No; iron or steel mallets.

5036. What is about the weight that a man has to carry with all his boring tools?—It varies a good deal.

5037. But what is about the heaviest?—It depends entirely upon the nature of the ground; sometimes a man may have 3 cwt., and perhaps some men have not more than 20lbs.

5038. So that if a man has to climb a ladder he has to carry that weight?—No; they never carry their tools along with them unless it is in a very shallaw place where they have no convenience near a shaft.

5039. I suppose that in shallow mines they carry their tools with them?—They do so very little now; not half so much as they did many years ago.

5040. But do they carry them sometimes?—They may carry a pick in their hand, and they might bring two or three borers on their back, but it is a very rare occurrence to see men bring up their tools.

5041. Do the men ever fall away from the ladders?—Occasionally, but seldom.

5042. From your experience of the man engine do you think that it is a very desirable thing for the man?—Yes; very desirable.

5043. And for the agents likewise?—Yes.

5044. Can you tell the Commissioners what was the cost of the man engine at Fowey Consols?—No.

5045. Do you know what it was at the Par Consols?—No; I never entered into that, to say what the expense was.

5046. Which should you say that the men prefer, tut work or tribute work?—Some choose tribute and others choose tut work. A man who has always been accustomed to tut work has a difficulty in working upon tribute, and a man who has always been accustomed to tribute has a difficulty in working upon tut work; it depends a good deal upon how they were brought up.

St. Austell.
Mr. F. Puckie.
22 April 1862.

5047. The men are paid once a month, are they not?—Yes.

5048. Are they two months in arrear of pay?—Some are. They give subsist generally for one month, and pay for the next.

5049. That is so in some cases, but not in all, I suppose?—In all.

5050. Not unless they apply to you?—We have a regular rule.

5051. For all?—Yes. Every tut-work man is paid subsist from our mines after working one month.

5052. How much?—One pound a man. The next month he is paid half his balance, and he will have subsist again for the next month, so that it makes no difference to a man upon tut work after the first month; the only thing is that he gets a pound a month sooner.

5053. Is that the general practice?—Yes, at our mines.

5054. That is all you can speak to?—Yes. At different mines there are different rules.

5055. We have been told that there are very few men in your mines on the sick list?—Very few.

5056. Do you know how many are away?—I do not think that in the Par Consols mine we have more than four or five sick men but what are able to do a little.

5057. Are any of those men, who are not quite well, working below?—We put those men who have got old, and disabled from working in the mines, to attend the dries, and so on; to dry the men's clothes and to do a little necessary easy work.

5058. Do the men who are somewhat affected in their breathing go down by the man engine and work?—Yes; some do who are able to work.

5059. Whereas, if they had to climb the ladders, could they do so?—They would not be able to go down them at all.

5060. They are now induced to go down because of the convenience of getting up?—They can work now down to the 240 fathoms as well as they can work on the surface, as far as that goes.

5061. So that, though a man is affected in his breathing, he can work below?—Yes, quite so.

5062. Do you think that many do work below who are affected in that way?—No doubt many, little or much; those who are slightly affected.

5063. So that they continue to work below ground although they are affected in their breathing?—Yes.

5064. You stated that the men were much healthier since the man engine had been there?—In our mine the men are in a very healthy condition, and have been so for years.

5065. Do not you see any particular difference in their state of health since the man engine has been established?—I think that it has improved.

5066. Is there a difference between the two mines, the Fowey Consols and the Par Consols?—Par Consols is not so deep, and it is not so hot, as the Fowey Consols, although I believe that the Fowey Consols' men live as long as the Par Consols' men do. I do not think that there is much difference in that respect.

5067. What is the general age to which your men work?—From 40 to 45.

5068. They do not work much after that?—I believe that that is about the average.

5069. (*Mr. Austin Bruce.*) The average of what?—As long as they live; they live to about an average of 40 or 45 years of age.

5070. (*Chairman.*) And you think that they work with you as long as they live?—Some may be home, perhaps, for a little while; it depends entirely on the disease.

5071. Do they go to seek other work after being at the mines?—Men are constantly changing from one mine to another; and in the different mines we have many old miners who have been perhaps working in the mines for more than 40 years.

5072. Do you think that the men would come from other mines to your mines, on account of your having a man engine?—Perhaps they would.

5073. But you do not know?—No; they are generally changing about.

5074. But at about 40 or 45 they generally die off; you have not many men older?—We have a great many above that age; we have men working now who are 60 years of age.

5075. And have they never been affected?—Not generally; some have been slightly affected, but not to disable them from working.

5076. (*Mr. Davey.*) Will you explain the position of those places where the damp air was which you spoke of where it extinguished the candle?—There are holes—places where the air is light—and while the air machines are idle perhaps it is damp (the machine is idle over night), and when the men come down the next morning perhaps there is a damp, and they are obliged to use the machine to break the damp and to throw air in.

5077. Does that occur also where the lode is not rich?—Yes; just the same as where it is rich.

5078. You have stated that some men were at one place where that occurred approaching a bunch of ore?—Yes, but that is not a general thing; there is no general rule.

5079. You have not so many men comparatively working there now as you used to have at Fowey Consols?—No, not by a great many.

5080. Did you find the ventilation equally good when you had so many men there?—There was very little difference.

5081. (*Mr. Austin Bruce.*) You stated, I think, that the lowest depth at which men are now working in the Fowey Consols is 270 fathoms?—Yes.

5082. I suppose that the natural heat there would be very considerable were it not for the ventilation?—Yes.

5083. The deeper you go the hotter it is?—I do not know that it is so. I do not think that we find it hotter at the 270 fathoms than we did at the 200 fathoms. Even when the mine was only 180 fathoms deep it was hotter there than it is now, because it is better ventilated.

5084. Generally speaking is it hotter at 200 fathoms below the surface than at 100 fathoms?—No; I do not believe that it is.

5085. You stated that at the deepest part of the Fowey mine it was as cool as on the surface?—So it is in some parts of the mine.

5086. And you said that that was in consequence of the quantity of air introduced?—Yes.

5087. The air introduced is of the same tempera ture as the air at the surface, of course?—Yes.

5088. The air must be affected I suppose by the heat of the place through which it passes?—Yes, after it passes a certain distance.

5089. How is it brought down from the surface to the bottom?—It comes down perhaps one shaft, and goes up another.

5090. Through the shaft?—Yes.

5091. Not through a pipe?—No, through the shaft itself.

5092. In its progress downwards it must be affected by the temperatures through which it passes?—No; I think that the shaft is as cool at the bottom as it is at the top.

5093. If there is more heat at the bottom than there is at the top, does not the air take in some of that heat?—Perhaps it may take in a portion.

5094. Can it do otherwise than take in a portion?—I should think not.

5095. Then it follows that do what you please the air must be hotter at the bottom than at the top?—I cannot give the exact particulars of that. I know that we have a very good ventilation at the bottom of our mine; it is very cool.

5096. I do not deny that; but I ask you by what means you can prevent the air which descends from taking in some of the heat which exists at the bottom of the shaft?—The only thing is, that after passing through certain levels, and so on, it may take in some

of the heat; there is no doubt about that; but the air apparently is as cool at the bottom as it is at the top.

5097. The longer it is there the hotter it gets, of course?—Of course; but it is constantly passing.

5098. Would a man standing still at 270 fathoms in your well-ventilated mine perspire or not?—No; he would not perspire standing still where there is good ventilation.

5099. Do the men who work there perspire?—A man perspires almost working anywhere.

5100. Do the men working at that depth perspire more than the men who work 100 fathoms below the surface?—They may in certain places, because of course there are certain changes, and so on. They may perspire more at one place than at another; and as another thing, perhaps, the ground is very much harder to work upon at one place than at another, so that that may cause an increase of perspiration.

5101. But my question is directed entirely to the ordinary heat of the air apart from the nature of the ground?—I do not think that they perspire much more at the 160 or 170 fathoms than they will at the 100, beyond certain places.

5102. How far is the furthest close end, at the 270 fathoms from the shaft?—It is about 200 fathoms from the shaft, and about 30 fathoms from the nearest winze.

5103. In that close end is there any artificial ventilation?—No.

5104. How many men are working there?—Six.

5105. Have you visited them lately?—Yes, I saw them last week, last Friday.

5106. Did they complain of poor air?—No.

5107. Did you find the air good?—The air was very fresh when I was there, but it was hot.

5108. Did you use no sort of artificial ventilation at all, but did you leave the air to find its own way in and out?—We have done so there.

5109. Although the men did not complain, do you think that those men would not be much more exhausted at the end of the day than men who were working in a better ventilated part of the shaft?—Certainly.

5110. Do you think that they could do that often without permanent injury to their health?—I do not know. Certainly it is more injurious to health than working where the air is fresh and where it is not hot, and where the men do not perspire so much.

5111. Had these six men driven the whole way forward from the last winze?—No.

5112. How long had those men been in that close end?—They had been there three or four months.

5113. Do you observe any difference in their appearances since they have been there?—No.

5114. Why did the pair before those men leave that end?—They were relieved, they were taken from that end and put to another.

5115. Why?—Because they were the men who looked after the working of the shaft, what we call sumpt men, and they had so much work to do in keeping the pit work in order. We were not driving that end as fast as we could wish, and we put them in another place, and put another pair of men to do nothing else but work that end.

5116. How soon will this end communicate with the winze which is being driven from the 260 fathoms?—As soon as we can cut through the cross course and drain the lode we shall commence sinking the winze at once.

5117. How soon will that be?—It may be in one month, we cannot tell.

5118. Do you believe that the men can go on working in this end for another month without having their health effected?—Yes, and perhaps for six months or longer than that.

5119. How do those men return to the surface?—By the man engine.

5120. The whole way?—From the 240 fathoms, that is the bottom of the man engine, they climb 30 fathoms.

5121. You say that the men never complain to you?—But seldom, you may find them complain occasionally.

5122. Do you think that there are any grievances which they know by experience would not be remedied whether they complained or not?—Some will complain; we can always tell when men ought to complain as well as the men themselves, and we always know when the places require ventilation, and as soon as ever we think that the men in a close place require ventilation we feel it our duty to put means to do so.

5123. You stated that there were some places in the mine where the powder smoke remained for half an hour before the place was fit for working in?—Yes.

5124. What sort of places are those?—Perhaps where they are 20 or 30 fathoms off from ventilation.

5125. Do you believe that places in which the smoke remains half an hour before it can be removed are supplied with sufficient air for men to work in as hard as those men are expected to do?—They are much better places than some where there are not the artificial means for throwing in air.

5126. Do you think that those places in which the smoke remains for half an hour can be as well ventilated as those in which it only remains for five minutes?—No.

5127. Then whatever difference there is must tell upon the health and strength of the miner?—Certainly.

5128. Do you not think that it would be a useful rule wherever the powder smoke remains more than a certain time, say more than ten minutes, to introduce a current of air?—I hardly think it necessary if the powder smoke remains only ten minutes because men generally speaking when they have blasted a hole go back and sit down perhaps half an hour to rest from their work; and not only that but sometimes they will have occasion to blast two holes together; then perhaps they will eat their dinner.

5129. But would not the fact that the smoke remained there so long, be a proof that the air was not sufficiently fresh, that it did not change fast enough?—Certainly. But I think that we should have something to do to work the mines if we endeavoured to put air into all those places. I think that there would be very great difficulty in doing it.

5130. But you would not deny that men can do more work where the air circulates freely, than where it is dull?—They can.

5131. And that it would be as much to the advantage of the employers as of the men to improve the air in that respect?—Not altogether; perhaps they would not do a great deal more work if they had better air; they would not work perhaps a greater number of hours, and perhaps they would stop from their work just the same.

5132. Even if they did not work a greater number of hours they might work more heartily while they were at it?—We have not many of those places which injure men by working.

5133. You have no places which would injure men in a week or a month?—Yes.

5134. But do you think that men work long in places where the powder smoke remains half an hour?—Yes.

5135. Without injuring their health in the long run?—I cannot say about that, I do not know but what it might injure them, but I do not think that it would injure them so much perhaps as a good many many would calculate upon.

5136. How many shafts have you at the Par mine?—I suppose more than ten.

5137. How many have you at the Fowey?—I suppose more than 20.

5138. I suppose that these do not communicate with each other?—Yes, many of them do.

5139. The Fowey and the Par?—No; they are two separate mines.

5140. Have you either at the Fowey or at the Par any shafts which are always used as down-cast, and any which are always used as up-cast?—No.

St. Austell.

Mr. F. Puckle.

22 April 1862.

5141. Upon what does it depend whether a shaft shall be an up-cast or a down-cast ?—They change, we often found that they change ; sometimes the air goes down one shaft, and it may come up the same shaft and down one and up the other ; they will change occasionally.

5142. Do you think that it would be a good thing so to direct the currents of air as to make some shafts always the up-cast and some always the down-cast ?—Perhaps it would be a very good thing or it might not be, we cannot tell. Sometimes perhaps we might ventilate one part of the mine best, and at other times we might ventilate another part of the mine best, so that which might work the best upon the whole we do not know.

5143. Have you the management of the ventilation ?—Yes. If we think that any thing in the way of ventilation is necessary we give orders to put in trap doors, and so on to throw in air to a certain place.

5144. Who is it that judges what should be done for the ventilation of the mine ?—The agents do so.

5145. Are you one of those agents ?—Yes.

5146. Is one more than another responsible ?—No.

5147. Each is responsible for his own mine ?—Yes ; we all consult each other ; one is responsible as much as the other.

5148. Have you ever examined the ventilation in the mines out of Cornwall ?—No, I have never visited a mine out of Cornwall, but I know that we have in the Par Consols, more particularly where our new engine is, the draught playing down exceeding strong; we see the draught playing down that shaft, and it plays up, we do not know why it is.

5149. (*Chairman.*) You have said that you expect in about a month to sink a winze which will ventilate the end where there is poor air ?—We hope to commence it in about a month.

5150. How long will it take before it is done ?—We cannot tell to two months, it will depend entirely upon the nature of the ground.

5151. You cannot tell how long it will be before it is completed ?—No.

5152. It may be three or four months ?—Yes.

5153. It may be six months ?—No, I do not think that.

5154. It may be four months ?—It may be four months.

5155. Until that is done that end cannot be properly ventilated ?—No, except by machines.

5156. (*Mr. Kendall.*) you can get no natural ventilation ?—No.

5157. But you can force air in before that ?—Yes.

5158. (*Mr. Holland.*) We have been told that miners at 40 or 50 look as if they were 50 or 60 ?—Some may, and some look very well ; some look healthy and strong, and some look perhaps very delicate.

5159. We are told that the class of miners look about ten years older than they are ; is that true or not ?—They look older than other people—than men who are always working upon the surface ; they look more delicate, but I believe that their health is generally speaking as good.

5160. From your experience do you believe that mining is a healthy occupation ?—I enjoy very good health, and I have been working at as bad a place as there is in any mine.

5161. Are miners as a class a healthy race ?—You cannot expect miners to live as long as other men.

5162. Why do not they ?—I suppose it is by working in poor air.

5163. Why do you think that they are not a healthy class ?—I suppose that it is perhaps by working in bad air, and so on, under ground ; the air is not so pure as it is on the surface of course, not in some places. I do not see why it should be otherwise than that.

5164. Is that true of the Fowey miners as of others ?—They are just the same as other miners in the county, taking the county through, I believe.

5165. Do you know other miners generally as well as Fowey miners ?—Yes, they change ; perhaps a Fowey miner may be here and there, and down west, perhaps, in two or three months.

5166. And the Fowey miners are not much better than the others ?—No ; they are just like them.

5167. You have spoken of the 270 fathoms ventilation ; is it the up-cast or the down-cast shaft that it ventilates from ?—That I think is a down-cast shaft.

5168. Just look at this little sketch which I have made ; will the air enter the upper or the lower of those levels first ?—It generally comes at the lower level.

5169. Why is that ?—I do not know ; perhaps sometimes it may come in one way and sometimes another ; it may go from this shaft perhaps to a shaft back there (*pointing to the sketch*).

5170. Taking this particular case, of these two particular levels of 260 and 270 fathoms, do they communicate from the same shaft, or from two different shafts ?—From the same shaft.

5171. Does the air enter the shaft at the lower of the two levels ?—Sometimes at one and sometimes at the other ; sometimes perhaps it may come up and sometimes it may go down; sometimes it may be going in this way and sometimes in that way.

5172. Does it vary constantly ?—Occasionally. I do not say very often, but you will find it so.

5173. Is there anything like a strong current through this part of the level close to the shaft ?—Yes, in some places.

5174. I am speaking of that place, and not of some places ?—It is not over strong there ; you can carry a candle very well.

5175. When you hold a candle still, is it blown away much ?—You will see it blowing ; but it is not blown out.

5176. To keep that flame alight, how fast must you walk ?—I am sure I can hardly answer that question. If you have no draught at all somewhere, of course, by walking, the candle will flare.

5177. I speak of this particular spot ?—There is a very good ventilation there, that is all I can tell you.

5178. I want to know what you mean by a very good ventilation ; at what rate do you walk in this particular level to keep the flame alight ; have you ever noticed that ?—We very seldom take that observation, we generally go fast and a little faster than that.

5179. You have five or six winzes in those two different levels, have you not ?—I do not know how many there are, but about five or six.

5180. Are those all open ?—No ; if we went this way (*pointing to the sketch*), we should perhaps do away with that winze.

5181. Do you close the winzes as you pass them ?—Yes ; perhaps all this ground may be taken away and we fill up that hole if possible with deads and that will throw a stronger current of air to the present end.

5182. Is that done ; are those winzes closed ?—Yes, generally speaking, if it is required they are ; sometimes, perhaps, we have air enough without doing that.

5183. How do you judge with regard to its being required ; if your candles will burn are you satisfied ?—Yes ; if we have air sufficient to work we are satisfied.

5184. How long does the powder smoke hang about at this 270 fathoms end ?—Perhaps the men are obliged to stop half an hour every time they blast their hole.

5185. Is it ever so much as an hour ?—Perhaps they may sometimes stop as much as an hour, because they may sometimes stop even longer than is required.

5186. Is it sometimes an hour before they can go into it again ?—They need not, I should say, stop so long as that ; they have to judge for themselves.

5187. How long is it common for them to stop out ?—I should say that it is necessary for them to stop half an hour.

5188. With regard to blasting, you told us that accidents happen in blasting from filling in the hole with killas, which sometimes strikes fire by tamping it in?—Perhaps it is for the want of putting killas in. They may put in perhaps a hard substance; they may put in spar, and not the proper material.

5189. Do they habitually put in some soft substance, such as paper or hay?—They generally put in something soft upon the powder; they take up some fine stuff from the bottom of the level, and put it upon the powder.

5190. Do they habitually put in soft stuff, such as paper, or hemp, or tow?—Not as a general rule; sometimes they put in dry clay.

5191. That is very good, if you have it; but suppose that you have not it?—Then they will take up some fine stuff from the bottom of the level, as fine as flour. A wooden rammer would not do in all cases.

5192. (*Mr. St. Aubyn.*) Would a copper one do?—Yes; it might do better, because it would not strike fire.

5193. (*Mr. Austin Bruce.*) If a wooden rammer would not do at all times an iron rammer would be necessary sometimes?—Yes, of course.

5194. Can an iron rammer be used without a certain amount of risk?—There is a difference in the nature of the ground; some ground requires harder tamping than others. A good deal depends upon the difference in the hardness of the ground.

5195. (*Mr. Holland.*) But is it not a proper thing to use that which is always safe?—Of course it is.

5196. Why not use a copper rod?—The only thing is, that it is more expensive; but I do not think that we ought to find fault with that in a copper mine.

5197. How much more expensive is it?—I suppose as four to one.

5198. How long will it last?—I suppose iron would last longer than copper.

5199. But how much difference is there?—I cannot tell.

5200. Would a copper rod last a man nearly his life?—No.

5201. Would it not last 20 years?—It would last a long time there is no doubt.

5202. Mr. Fox proposed a tamping wedge some 20 years ago; do you know that?—No.

5203. (*Mr. Kendall.*) With respect to the draught in the mines, how many fathoms is Henrietta shaft, in the Fowey Consols, from Bottry's shaft?—I should say 100 fathoms or more.

5204. Say 270 fathoms; Henrietta shaft is not holed down to 100 fathoms?—No.

5205. Supposing it was holed, would the draught be such there, without doors, as would put your candle out very frequently?—Yes, it would.

5206. Supposing that a man stood still at the 270 fathoms from the adit, which would be 300 fathoms from the surface, would not he catch cold very soon from the draught?—Yes; certainly.

5207. Much sooner than at the surface?—Yes, I believe so.

5208. Take our mines generally, is not there a very strong draught, a sensible draught, in all our large mines?—Yes, there is; sometimes you can hardly carry a light through a level; and if a person stops in that draught no doubt he will very soon take cold.

5209. With regard to tamping, your instructions always are to put something in very soft on the powder?—Yes.

5210. And, among other things, you recommend the fine stuff which comes out of the boring?—Yes.

5211. It is the finest dust?—Yes; as fine as flour.

5212. If you struck the iron as hard as you could against that dust a thousand times, you could not create a spark?—I do not think you could.

5213. You put in that first?—Yes, we always order so; but I believe that sometimes it is seriously neglected.

5214. And your belief is that when an explosion takes place it arises from the miners not following out the orders given them by the agents?—I should say so.

5215. (*Mr. Holland.*) About how far is the furthest end from the man engine below?—I cannot tell I am sure; there may be pernaps some ends 300 or 400 fathoms from the man engine.

5216. Or more than that?—Yes.

5217. Half a mile perhaps; 800 fathoms?—Yes; but I speak of the principal parts where they are working; there are places, perhaps nearly half a mile, where they are not working now.

5218. Do the men always prefer going underground that distance to the man engine, to going up the nearest footway?—They will go to the man engine if they can get at it; sometimes they may have hundreds of fathoms, and may have to go up 20 fathoms climbing before they can get to the man engine, or sometimes down that distance before they can get to the man engine.

5219. Still they will go to it if they can?—Yes.

5220. If the man engine is stopped by any accident, will not they rather wait a long time than come up by the ladder?—Yes; they will rather wait three or four hours than climb up.

5221. Before the engine got into use, did any of the men prophecy that it would never answer, and say that they would never go up by it?—Not that I recollect.

5222. Were you at the mine at that time?—No, not at the Fowey Consols.

5223. You have heard of such things being said at the mine, have you not?—I heard some say that they did not approve of it, and that it would not do, and they would be afraid to ride in it; but I believe that everybody is satisfied with it now.

5224. Is it not likely that prejudice against those sort of things will die as soon as that did?—Yes.

5255. Provided it be prejudice?—It is a prejudice, no doubt.

The witness withdrew.

CHARLES BARHAM, Esq., M.D., examined.

5226. (*Chairman.*) I believe that you reside at Truro?—Yes.

5227. You were employed in preparing a report for the Children's Employment Commission?—Yes.

5228. In preparing that report, had you an opportunity of becoming acquainted in a special manner with the families of miners and with miners themselves?—Yes; I became pretty largely acquainted with the whole class, more especially with those actually at work.

5229. Did you observe anything in the state of their health to attract your special attention?—Yes; there were many things which were very striking at first sight; but the general results were rather those derived from an examination of the registers of deaths; and the evidence which I collected more quietly than from direct observation. But under the eye of the medical man there are many things regarding miners which are very observable as different from the other classes of the community.

5230. You have the principal charge of the Infirmary at Truro?—I am the senior physician to the infirmary.

5231. Have you an opportunity in that capacity of observing any diseases of miners?—A considerable number of miners are admitted as patients. It is not at all exclusively a miners' hospital.

5232. Have you had any opportunity of comparing the diseases of miners with the diseases of other patients?—Certainly.

5233. (*Mr. Holland.*) You are also in free com-

munication with a large number of medical practitioners throughout the county who practise among miners?—Yes.

5234. (*Chairman.*) Is the subject of the miners' disease ever a topic of discussion between others in the medical profession and yourself?—Yes. The influence of mining occupation becomes a topic of discussion when miners are attended. When I have to meet medical men in consultation, who are in attendance on mine agents or on miners, the influence of their particular occupation becomes a considerable element in the discussion as to the nature of their case; but I should say that by far the largest proportion of the diseased conditions of miners does not come very much under the observation of the hospital physician; it is rather a deteriorated state of health, which does not immediately bring them to the hospital, which tends to shorten their lives very materially as compared with the rest of the community; perhaps they die off without ever becoming patients in the hospital; and they are not, perhaps, very much patients even out of the hospital.

5235. Is there a general agreement, in your opinion, amongst the medical men as to the nature of what is called the miners' disease?—Yes; I should say pretty generally. Some persons have particular views as to the causes in the earlier stages of the disease, and the particular character of what is, perhaps, called miners' consumption; whether it is more of the nature of what is called tubercular consumption, or whether it is the result of inflammatory changes in the lungs, and so on; but there is generally speaking no essential difference prevalent upon the subject.

5236. What would you describe as the miners' disease, in your opinion?—My own view, as far as the facts have come under my notice, is confirmatory of what I had occasion to state more than 20 years ago, in 1841, I think, when I reported before. I had then had a pretty large opportunity of seeing the mining population, both in the mining districts of Devonshire, in the neighbourhood of Tavistock, and in Cornwall; and my opinion remains the same, namely, that there are two large sections of the diseases of miners which are, I may say, essentially distinct; one the diseases of the young miner in early life up to, perhaps, about 25, which is partly ordinary consumption,—what we call scrofulous consumption; such as might occur in the general body of the community, and especially in those who are shut out from free access to the air, and who are exposed to mechanical causes of irritation of the lungs, and other agencies which tend to ripen the seeds of consumption rather speedily, and to interfere, perhaps, with the full development of the body. And there are also at that age a large amount of inflammatory affections of the lungs, such as arise from rapid changes of temperature,—what we call bronchitis and pneumonia, pleurisy, and so on, and occasionally spitting of blood. And secondly, what is more properly miners' consumption, which finishes the originally healthy and sound miner when he gets perhaps to be from 40 to 50 years of age, and upwards, which is a slow disease, the result of his occupation purely, I think, as being the effect of impure air and the inhalation of mechanical particles,—irritation of the lining of what we call the bronchial tubes,—the air tubes; and also the effect of climbing to a considerable extent, too great a strain upon the heart and upon the chest. Those two classes of disease require to be kept distinct by any person who would investigate the effect of mining occupation, both on scientific grounds, because they are capable of being obviated in very different degrees. You may say that a very large amount of mischief is done (at least that is my own opinion) by subjecting boys at very early ages to the influences which they must sustain when they go underground. That is a conviction which I hold very strongly, that in the growing age, the early age of life, it is much more prejudicial comparatively than it would be at a later age, to introduce them into places in which the air is very impure, in which their physical powers are overtaxed, in which their digestive organs are very much thrown out of sorts, and in which their natural course of development is seriously interfered with. That, of course, was an element with which we, in that early Commission with regard to the employment of children, had a good deal to do. The employment of very young boys underground was a thing which it was my duty to point out as one of the practices which might be very properly corrected in this county.

5237. You have referred to the inhalation of mechanical particles, will you explain what those particles are?—There is a great deal of carbonaceous matter in the first place from the burning of candles and from powder smoke.

5238. (*Mr. Holland.*) The imperfect burning of candles?—The imperfect burning of candles. Then there is a certain amount from the operations of the miner,—dust and so on;—but that is not so considerable. There is a large accumulation in the ends which are not within reach of efficient ventilation. You may say that a mine is like a chimney if you get into a corner, if you get into an end; the ventilation may be very good a little way off, but the end itself is rather beyond the point which is ventilated: this is constantly the case in mining operations. You have to carry on the operations beyond where efficient ventilation yet exists, and in those situations after blasting, and to some extent even from the mere burning of candles, there is an accumulation of carbonaceous and other particles, and there is also a great deterioration of the air from the consumption of oxygen, and the increase of carbonic acid.

5239. (*Chairman.*) Do those particles affect the bronchial tubes or what part?—They affect immediately the bronchial tubes, and in some measure the minute vesicles,—the air vesicles—the more minute structure through which the air acts upon the blood; and the impure air deteriorates the quality of the blood, and so far depresses the power of life. It is a constant occurrence in such places that the miner for a long time after he comes up spits black stuff. Any persons going down for some time, mere civilians, going down if they choose to stay long enough, say six or eight hours under ground, and get into these ends, will find that they spit this black carbonaceous matter. That is got rid of pretty readily in the first instance, and perhaps in the earlier years of the men's mining, but I believe that gradually the contact of these particles damages the delicate structure of the air tubes and vesicles, and that the secretion which throws that matter off is lost; and the older and healthy miner, in my opinion, gets damaged very much by that cause, by the repeated effort to spit up this carbonaceous matter, just as any one might do from inhaling dust for a long time. He gets rid of it naturally by expectoration for some time, but if he had to do it day after day, the texture of the lining of his air tubes would become injured, and the lungs themselves would be damaged in consequence. The miner has a species of disease which lessens his power of expansion of the lung, and in many instances he dies of a chronic consumption; but in other instances by a sort of want of breath, a contraction of the lung without any great amount of destruction.

5240. Is there any injury arising beyond the mechanical injury from the powder; is any noxious gas created by the powder which is injurious to health?—Not seriously. I should say that though such gases are commonly generated they are not seriously noxious in our mines.

5241. I mean by an explosion of powder?—There are sulphurous acid and different gases which are noxious; but I do not think that they really constitute a material element in the injury done to the miner; not anything seriously so.

5242. Supposing the candle to be made of any deleterious material, would the inhaling of that be likely to be injurious?—Yes, it has been found so in other mines, such as in some of the Scotch collieries it has been found in a very marked form; but I do not

think that anything considerable is to be attributed to it in our Cornish mines as far as it has come under my own observation. There is some difference in candles, but it is not a very material thing.

5243. Have the candles in this district ever been analysed at all?—I think not. I do not recollect any analysis. Of course bad candles are disagreeable, but I do not consider it at all an important matter in relation to our mines. The influence of climbing is one very essential element, I have no doubt.

5244. Supposing that a man working in good air had to climb 200 fathoms, would that be injurious to him?—It would be the most fatiguing part of his day's work.

5245. I mean as affecting the air tubes of the lungs or the heart?—In early life it would tend to produce some injury to the heart; I should say in a general way, that diseases of the heart are not frequent amongst our Cornish miners. Diseases of the heart have been supposed and stated, I believe, to be frequent, and one great cause perhaps of mortality. My own experience contradicts that; I believe, that what we should professionally call disease of the heart is not common; I have found the effects on the heart of great exertion very marked in young subjects; the heart is in a state in the first place of palpitation, the young miner likes to go up pretty quickly if he is climbing a ladder, and will run a sort of race with his comrades. Then of course they are like persons running a race up hill, there is a violent beating of the heat induced, then the heart gets, to a certain extent, stretched, it gets exhausted by the time they have finished the race, and if you were to examine one of the miners on his coming to the surface you would find that the heart was exhausted and acting very rapidly and feebly, and sometimes irregularly. If you were to see a party of miners who had just come up, especially the younger ones, you would find that to be the case in a marked degree. Then the subsequent result of that is, that as the part exercised gets an increased nutrition, in consequence the heart gets enlarged and beats strongly. But the miner does not complain of that: I have frequently examined young fellows, whose hearts when they have come to the hospital have been beating strongly, whose cases would perhaps be set down as diseased heart in a London hospital, and who would not themselves be sensible of anything going wrong; they are accustomed to the heart beating a little strongly; but that is a condition which a period of rest will do away with; it should not be called disease, it is the effect of causes which no doubt will tend to injure the heart ultimately, but it is not really a diseased heart. The older miner is not frequently subject to what is technically called disease of the heart, disease of the valves of the heart, it is a comparatively rare occurrence; but the effect of climbing is doubly injurious, it causes from the amount of perspiration, and of exhaustion, a very great susceptibility to the impression of temperature and to catching cold, and so on, and a large portion of the pulmonary diseases of miners, especially of those of the younger miners, are in fact inflammatory diseases, which may be caught in that way, inflammation of the lungs and of the air tubes, bronchitis as it is called. A very large amount of the disease of the younger miners is of that nature; the exhaustion from climbing affects doubly in that way, it causes a liability to other diseases, and it produces in itself a weakness of the heart, and an inability to resume labour with the same advantage, and some interference with the digestive powers as well.

5246. Is there a thickening of the membranes of the heart?—No, not of the internal parts of the heart, it is rather an enlargement of the heart with some degree of thickening of its walls.

5247. As you state that the climbing and the work below render a man peculiarly liable to cold, it is important that he should have on coming to the surface a proper place to change, so that, as far as possible, catching cold may be obviated?—Yes. A recommendation was introduced into the former report of driving a shallow level to the changing place from the shaft where the men come up, so that they might come into a warm changing house where their clothes could be dried; I think that since the time when that report was written considerably more attention has been paid to those matters; and at that time, the man engine had not been introdnced at all. It strikes me that it would be a very important thing to ascertain what the effect of the introduction of the man engine has been as regards the health. My own impression is strongly, that it has been very beneficial as regards the prevalence of pulmonary disease and general disease amongst the miners, and that opinion has been supported by the reports of some of our most able mine agents, the late Captain Jennings and Captain William Francis, who were both very able men, and Mr. G. Michell, of Redruth; they all reported to me some years ago, and I drew up a paper on the subject, representing the favourable influence which had resulted from the introduction of the man engine, in reference to miners' consumption, and to the general affections of the chest of the miner. That has been much more extensively introduced now.

5248. How do they judge of that improvement?—They judge partly from their observation of the men and partly from the results on themselves; Captain Jennings was the agent at Tresavean, one of the largest mines which we had at that time, and one of the deepest, it being 340 fathoms from the surface, and he was afterwards at Seton; I think he was agent of another large mine; he had been a patient of mine sometime before, and had had an affection of the lungs, induced by climbing as I considered at that time, and he was very well satisfied of it afterwards. After the introduction of the man engine he was able to resume his work without difficulty, and he stated to me, in a report, that he was satisfied that he should have added many years to his life had the man engine been introduced before; that a number of men who had been employed in that mine had been able to be put underground again who had been obliged to give it up, and so on.

5249. You have stated that a captain was able to go below ground because instead of climbing the ladder he had a man engine, although he was previously affected?—Yes.

5250. Would not that be the case with many other men who with the man engine would be able, though affected, to work below ground, which they would not have been able to do if they had not had a man engine; and therefore would not there be fewer men put off work although there would not be fewer men, in fact, affected by disease?—Unquestionably. A certain amount of disease would be consistent with their continuing at work, because the climbing being the most difficult part of their work, if a man's breath was short, he could not climb; perhaps a comparatively slight disability would prevent him from climbing from a great depth, whilst he could continue, if he could just be relieved from that one difficulty.

5251. Therefore in any inquiry as to the number of men who were obliged to leave the mines from disease that would diminish the number, because there would be so many who could continue to work?—Certainly.

5252. So that it does not follow that the climbing produces the disease, but the man engine may enable a diseased man to work longer in the mine?—It does not follow from the particular evidence that the climbing produces disease; but there is sufficient evidence of another kind, that the climbing naturally tends to produce disease both by exhausting the general power, and particularly by exhausting the heart and also causing, from the act of climbing, a great stretching of the lung, because the miner has to keep the chest as a fulcrum for motion; he must keep the chest pretty full when mounting, and that causes one affection of the chest to which the miner is to some extent subject, what we call dilatation of the bronchi, and emphysema, though, in my opinion,

ST. AUSTELL.

C. Barham, Esq., M.D.

22 April 1862.

that is not a prevalent disease among the miners. There may be perhaps some portions of the lung which may be subject to the emphysema, which consists in the breaking up of the minute vesicles or air cells; that may occur in detached and small portions of the lungs, but it would be difficult to ascertain it exactly without post mortem examination, which is very little practised among our miners as compared with other artizans. The miners object to it. That minute emphysema can hardly be distinguished during life; but what would be recognised as emphysema elsewhere has not been a prevalent disease under my own observation. There is very little expansion in the upper part of the lung in the disease of the miners, and there is not that resonance which there is in an emphysematous lung.

5253. Would the climbing tend to produce that disease?—The climbing would tend to stretch the air tubes, and there may be other causes which perhaps would be a set off against that.

5254. (*Mr. Holland.*) Then do you consider the existence of emphysema of the lungs rather hypothetical?—I do.

5255. (*Chairman.*) Have you ever turned your attention especially to the examination of the emphysema?—We are constantly examining the chest. My own experience is that there is not, generally speaking, a very resonant chest in the miner who characteristically has the miners' disease; he has a rather contracted chest; the upper part of the chest does not expand, it is more like what occurs in chronic pleurisy.

5256. Do many boys work under ground?—I do not think that the proportion is much altered. I have not the evidence before me as to the number at this time in the mines from which I before had returns. Between the ages of 13 and 18 there were 1,364, and under 13 there were 550; but the latter were not all employed under ground, the greater part of them were at the surface.

5257. (*Mr. Austin Bruce.*) Were the 1,364 employed under ground?—No; but after 13 a very large proportion were employed under ground.

5258. (*Chairman.*) In calculating any change which may have taken place in the health of the miners during the last 10 or 20 years would you not take into account the number of miners who have emigrated?—Undoubtedly it is a necessary correction in estimating the average duration of work and the average of death. It is quite necessary to examine how many have gone abroad, and to some extent, I should say, it ought to be ascertained how many leave the mining occupation; it ought at least to be estimated in one or two districts, so as to be applied as a general correction.

5259. Have you any means of estimating the number of miners emigrating from Cornwall?—It would be a troublesome thing to do for the whole county, but it might be done in one or two districts without difficulty, for the miners are a set of men very well known to the agents in the different mining districts. There would be no difficulty excepting the employment of a few clerks and a little expenditure.

5260. You believe that it might be ascertained?—I believe so, without difficulty.

5261. Is it at all within your knowledge that young men who have found themselves affected by working in the mines here have emigrated?—Yes; I have had occasion to be consulted by miners who not feeling equal to the work at home have asked me whether they might go abroad. I have encouraged some of them to go, and have known that they have gone and got on well.

5262. Have you ever heard whether they have recovered their health?—I have heard of them as doing well and being able to continue their work.

5263. In any statistical inquiry as to the improvement of the health of the miners that should be taken into account?—Yes, certainly; it would be quite necessary, supposing, as I believe to have been the case for some years past, that a very considerable number of miners have emigrated in that way. Then it would be very essential in order to arrive at a just conclusion as to the duration of their working age and also the relative mortality as given in the Register of Deaths, to ascertain how many had left, and at what ages, as far as it could be done.

5264. (*Mr. Kendall.*) Have you ever descended much into our mines?—Not very much.

5265. You have been down?—Yes.

5266. More than once?—Yes, I have been down Botallack and Huel Vor in olden times.

5267. Then you have been down some of our deepest mines?—The Huel Vor to the 200 fathoms in the old working. I went down to make some observations on the temperature below ground a good many years ago.

5268. Did you go down with regard to the temperature, or with regard to the ventilation?—To the temperature solely at that time, at the time Captain Tyack managed it.

5269. I understand that your great experience among the miners is with those whom you see as physician to the hospital?—Yes; and I see a large number of miners who consult me from time to time. I see a great number of miners in the course of the year; miners at home and from our colonies, from Mexico and Cuba, and so on; a large number come from time to time. I have what may be called a diffused experience of the mining population; it is not concentrated in a particular mine, but I think I have a very good selection.

5270. As physician you are called in every now and then?—Yes, to the mine agents.

5271. And even to the lowest order of the miner class?—Yes, at times.

5272. Before a case comes to the hospital I suppose the party applying for admission is always examined by some local surgeon?—Yes.

5273. In order to know whether it is a case or not for the hospital?—Yes.

5274. In the case of miners, do the surgeons simply say, that it is a case for the hospital, or do they also enter into the minutiæ of the case?—We do not generally get a report from the surgeon, or even a statement that the party has seen a surgeon; but we know that he has, because they apply to the mine surgeon; but you know that persons who are supplied by contract are not always satisfied, and so they come on to the hospital. They have been previously attended, but we generally get no statement from the surgeons prior to their introduction to the hospital; they get recommended from the mine or from subscribers.

5275. I understand from you, that as far as the younger miners go, there are more cases of danger arising from their catching cold than from bad ventilation?—I do not think that I said there were more; I said that the younger miners suffered more, I think, from catching cold than the older ones would do. I did not draw any comparison between that and the effects of ventilation.

5276. I want to come to that point. In cases, generally speaking, both as regards the old miners and the young miners, who get what is called the miner's disease, and who also get consumption, do you think that it arises more from bad ventilation or from their catching cold from rapid climbing, and so on, or that it is combined?—When you say "bad ventilation," that is jumping to a conclusion. I should say that it is a combined influence. It appears to me that the old miner suffers from the combined action of a variety of causes which have lasted through life. Supposing him to have been, as he must have been, a healthy and strong man originally, it is very much the combined influence of an impure atmosphere, acting from time to time, an excessive strain and exertion on the heart, and an application of mechanically irritating particles to the lining of the air tubes, as I explained just now. The ventilation, however, well carried out, could not prevent there being a certain

amount of difference in the air from that above in a place where they are blasting.

5277. Taking a number of mining cases, both in the hospital and in your own private practice, have you any idea of the per-centage of those who have complained to you that in their own idea their illness has arisen from working in bad ends?—A very large number of the older miners speak of poor air as being the cause of their ailments. I think they feel it themselves more distinctly; they have been, perhaps, working for some months in poor air, and then they feel that they have broken down; they have tested their powers to the utmost.

5278. In your conversations with them, have you been led to suppose that they have been working in many cases in very badly ventilated ends?—Certainly.

5279. More in olden time than now?—I have hardly the means of making a comparison. It has certainly struck me that the amount of cases of that sort has lessened of late, that has been the impression on my mind, and it has been rather confirmed by statements, which I have had from mine agents and mine doctors, that the condition of things has improved; but that I believe applies more to the great mines in the central districts, and so on. The outlying mines, I am inclined to believe, are often very bad in that way.

5280. I understand that some years ago you applied your mind very greatly to statistics, and since that you are led to believe that the ventilation is better, and that the climbing is better, but you have not any statistics to prove it?—I have not any statistics to prove it. I think that they are very desirable.

5281. (*Mr. Holland.*) Mr. Pearce of this town expressed a very strong opinion that there was a clearly marked distinction between miners' consumption and ordinary tubercular consumption; do you agree in that opinion?—Yes, as regards the disease of the older miners. I expressed that opinion just now to a certain extent.

5282. He also said that he was not quite sure that the proportion of deaths from tubercular consumption was as great among miners as among other men, that it was certainly not more; perhaps you have not noticed that?—Unless there were much more extensive post mortem examination upon that point than there has been, I should say that it would be mere guess work. There are no materials for medical men to say that the disease is not tuberculous unless the structure is examined.

5283. He also told us that miners' consumption more commonly attacks the lower than the upper part of the lungs; what is your opinion in that respect?—There are a large number of cases of younger miners who are affected with a sort of chronic pneumonia, a condensation of the structure of the lower part of the lung, which brings them to their grave without there being evidence of tubercles certainly.

5284. Mr. Pearce told us that he had found the unnatural sounds more marked in the lower than in the upper part of the lungs, and that he believed the miners' disease to be more frequently at the lower than at the upper part of the lungs; does that correspond with your observation?—Yes, it corresponds to this extent, that I believe there is a large class called consumption, which is in fact pneumonia, inflammation of the lung.

5285. He was confining his observation to the class called consumption, which he believed not to be consumption?—I should agree with him so far; but the cases of proper consumption, I think, are located just as usual.

5286. He was speaking of the class which the miners themselves called consumption, because it was accompanied by a cough and a spitting and a wasting away, but which he believed to be quite distinct from tubercular consumption?—A miner has of course very imperfect evidence as to his own case, he calls it consumption if he finds himself failing; but I believe the class is quite distinct to the medical man. There is a large class of cases which probably would be entered on the register of deaths as consumption, but which to the medical men are not consumption, they are chronic inflammation of the lung. The proper consumption, which is a very prevalent disease among the younger miners, is the ordinary consumption.

5287. Mr. Pearce was speaking of the consumption among miners which occurs particularly after 40 in the older men, as distinct from the less frequent cases which occur below 30. I think you agree with him in that opinion. He also told us that in that class of miners' consumption, properly so called, spitting of blood from the lungs was rather rare?—Yes, in the miners' consumption.

5288. In pulmonary consumption it is very common?—Yes, and so it is with miners in early life in ordinary consumption.

5289. He also told us that if miners were decidedly affected, but not very far gone, by a change of their employment, they very frequently, although they did not recover, lived many years, and then died; is that correct?—Yes, they live on. There is a considerable number who live on in any community. They are not much inclined to change their employment, but still a certain number of them do change it.

5290. He said that those who did change their employment, and were not very far gone, would remain valetudinarian for many years, but not very ill?—Yes, it would make a difference of several years of life.

5291. Supposing that persons were as much affected by tubercular consumption, would there be any probability of a large proportion of them living for many years?—No.

5292. The majority of them would probably die?—Certainly.

5293. Do not those circumstances confirm what you before stated, that the cases are two distinct divisions?—Yes.

5294. You say that you thought that a man engine had been very beneficial. There are only six man engines in the county, I believe, and those are in the deepest mines, and therefore, where they are most wanted?—Yes. Have you ascertained that there are only six?

5295. I have not ascertained that there are only six, but I have only heard of six?—I thought that there were more than that. The whole of those mines where the man engines are, embrace a considerable population.

5296. They also embrace the population which most need the help?—Yes.

5297. You have stated that disease of the heart is not frequent; I suppose a simple thickening of the muscular walls of the heart is frequent?—Yes; I drew a distinction between a temporary and a permanent thickening.

5298. A simple thickening of the wall, unless it were the consequence of some other disease, would not be a serious matter?—No. I meant to explain that it was rather an effect of excessive exertion, just as a muscle of the arm would increase in size by use.

5299. Therefore when we meet with hypertrophy of the heart in ordinary practice, which looks serious, it is rather that it points to that of which it is the consequence?—Yes.

5300. We fear that it is the consequence of some obstruction which has been overcome?—Yes.

5301. Therefore it is rather the mark of a serious disease than in itself a disease?—Yes.

5302. We were told by some of the miners that the candle smoke, by which they meant the smoke of candles burning in very poor air, was more annoying to them than powder smoke?—The smell of it.

5303. Do you think it likely to be injurious?—It would be injurious if carried to any great extent.

I am not competent to say what candles are used at the present time in all our mines, but generally speaking, if a lot of bad candles are sent in, the same

St. Austell.

C. Barham, Esq., M.D.

22 April 1862.

person is not employed again, or at all events some arrangement is made for their being better next time. It is not the practice here to use that sort of candle.

5304. You said that you thought mining much more injurious to growing than to mature age ; do you think that that is a fact which has been proved statistically ?—I think so ; statistically you may find, I think, that the mortality is great at an early age.

5305. That is, that miners who begin at an early age are less healthy than those who begin at a more mature age after growth ?—Yes, that is the result of my own inquiry.

The witness withdrew.

Captain John Webb examined.

Capt. J. Webb.

5306. (*Chairman.*) In what mine are you at present employed as captain ?—I am the manager of three or four mines, two in this neighbourhood and two or three in the west ; West Par, East Beam, and two or three little mines about Camborne.

5307. You were a miner yourself, and worked underground ?—Yes.

5308. How long ?—I commenced working when I was seven years of age in the dressing of ores, and I went underground when I was 15 years of age, and I was 56 last week.

5309. How many years have you been an agent ?—Nearly 30 years.

5310. But before that you worked underground ?—Yes ; before that I worked as a miner.

5311. At tribute or tut work ?—Principally tribute.

5312. Did you ever suffer in your health when you were working ?—No ; I generally worked in good air places.

5313. When you worked in good air did you ever feel any inconvenience from climbing the ladders ?—I was always cautious not to climb fast. I always knew that I should sustain an injury from that.

5314. In what depth of mine did you work ?—From 70 to 80 fathoms.

5315. Do you think that miners generally suffer in health from their occupation ?—Yes.

5316. Have you observed them suffer yourself ?—Yes ; they suffer from bad ventilation in many cases ; I do not say in every case, and they suffer from climbing too fast, that is their own fault.

5317. How far from a natural means of ventilation would it be safe in ordinary cases for a miner to work in an end ?—I do not think that they ought to work beyond 20 fathoms, although some places will convey air better at 40 than others will at 20. But there should be some artificial means when a level or gallery is driven on beyond 20 fathoms from a current or draught ; I think that there should be some standing rule of that sort.

5318. Must not that differ according to the depth of the mine ?—No ; I have seen the air as bad five fathoms deep as down 100.

5319. As bad at the end ?—Yes.

5320. How do you discover the air to be bad ?—We generally discover it to be bad from the slopedness of the candle burning.

5321. Do you also observe any difference after a blasting, as regards the smoke getting away ?—Yes ; the longer the smoke continues in a place the less current of draught there is to carry it off. It shows that the air is bad when the smoke does not pass off quickly.

5322. How would you obviate this defect ?—If I could not bring in air naturally, I should use some artificial means ; I should do it mechanically by putting either a fan or some other appliances which we use in mining; but a fan is the most effectual, and it is cheap.

5323. A fan worked by a boy ?—Yes ; or sometimes we work it with little water wheels if it is not more than two feet high, as well as by a boy.

5324. Will that introduce fresh air ?—Yes ; especially if we have metallic pipes through which we can deliver the air as good as we receive it, but if we have wooden pipes, wood is a consumer of air.

5325. In a dry mine, if the wood is dry, do you think that the air is injured by passing through wood ?—Yes ; I have observed wood in dry places throw forth a sort of moss or fungus, as it were, more than it does in wet places ; when dry rot takes timber it is more offensive than it is when it is wet.

5326. Is it the case in mines that there is dry rot ?—Yes ; and it throws forth very poisonous vapours.

5327. Therefore you think that the air should not be introduced by means of wood ?—No, unless it was well pitched over within ; I suppose that that would be a sort of remedy, but that is not done generally.

5328. But if it was pitched over so that it could not decay, do you see any objection to the use of wood ?—I think that that would be an improvement.

5329. It would be much less expensive than pipes?—It would be a little less expensive than metallic pipes.

5330. What kind of pipes would you recommend ?—Zinc or galvanised iron would do very well.

5331. Have you ever seen such a pipe as this employed, would this pipe answer for ventilation (*handing a black pipe to the witness*) ?—Yes ; I think that that would do very well for a pipe.

5332. Do you know anything about the size of pipe in proportion to the number of men at work ?—The pipe should be of tolerably good size ; if the aperture is a pretty good size there is less friction to the machine; eight inches would not be too much, but six would do very well.

5333. I suppose that it depends upon the rate at which the machine is driven ?—Yes ; it depends upon the velocity of the fan.

5334. Have you ever seen one attached to the steam engine at the surface ?—Yes ; I have applied them to the steam engine when we have worked the rotary engine, but our pumping engine will not do it, it goes one stroke and then stops and it would not revolve anything.

5335. You think that it could not be applied by an engineer to a pumping engine ?—No.

5336. (*Mr. Fulke Egerton.*) In a pumping engine there is a cessation between each stroke, is there not?—Yes. But there are little portable fans made by our founders here only about three pounds each, and they are very portable, and they have given air under ground very easily, and if we had metallic pipes and little portable fans in places where men are almost suffocated, and which is very injurious, I think they might have good air.

5337. Do you know any places where men are driving in poor air ?—Yes ; I frequently observe it in inspecting mines where men are 30, 40, or 50 fathoms off, and a little fan might give them a fresh supply of air.

5338. And yet that is not provided for them ?—It is not provided for them one time out of ten ; there are some agents more particular than others, but generally speaking it is neglected.

5339. Do you know of any instances in which, if the men had applied to those agents they would have allowed a fan ?—I do not know that they have made any direct denial of those things ; but men cannot say we will have a machine here. It is the agents' place to say that they will do it.

5340. Are there mines working in which there are none of these small machines ?—Yes, many mines in the county.

5341. So that if a man applied for them he could not get them at once ?—No. I do not know that I have heard tell of any flat denial to the men.

5342. But if there were none in the mine then they could not be applied ?—No, by no means.

5343. How long do you suppose a man could work in poor air ?—The general hours in the county are eight, but in some deep mines they work six.

5344. How long can a man work in poor air, how many hours consecutively ?—He ought not to work four hours.

5345. Do you suppose that they do work four hours sometimes ?—Yes, and eight very often.

5346. In poor air ?—Yes ; they ought not to be there more than four hours.

5347. But do they work eight hours continuously in poor air ?—Perhaps at their shift time they might remain idle for half an hour, or something like that, to cool, and very often when they come away from their mine they blast a hole, then they cannot go in there again perhaps for half an hour, and then they just lie in a place idle for half an hour for the smoke to clear away, whereas if they had a little fan they might blow in a little fresh air as well as being back in a current doing nothing.

5348. So that it is a loss both for the men themselves and for the adventurers ?—Yes ; I have been long urging that. I have never let men work under my guidance for many years in poor air, unless they were trying to hole or to communicate air to another place. I have said, if there is poor air I will have a fan or a water fall, or some appliances.

5349. But that is not the general practice ?—No ; or at least it is not general enough ; a great deal of the poor air might be avoided with a little attention being paid to it.

5350. Are there cases where you think that it could not be avoided ?—No place. If you have a fresh current of air you can always take it up from that place.

5351. And therefore it is neglect ?—It is neglected too often, I am sorry to say.

5352. Do you think that the men suffer in health from that ?—They must suffer in health when they are breathing such a bad atmosphere. You hear men complaining very often when they are climbing the ladders ; they know when they are working in poor air, they feel a weakness in their legs. I have not experienced it myself. I have generally worked in good air places upon tribute.

5353. Do the men go back again the next day to the same place when they find that the air is poor ?—Yes ; in most of our mines we keep three shifts of men, and they will relieve each other, and they may have half an hour before their relief time.

5354. Supposing a shift of men found the air bad, would they go on with the work for the whole month for which they had taken it?—Yes; very often, when men are in such a place they are reluctant to be out of employment, and they work and injure their health, and it goes on for years imperceptibly, perhaps, till it tells upon the constitution.

5355. They are obliged to work there for the sake of getting employment ?—Yes ; if they put themselves out of that place, perhaps they will be out of employment, which they cannot afford to be at all times ; when employment is not very plentiful they will work in these places for the sake of having work.

5356. And do you suppose that they know themselves that it is injurious to their health ?—Men get habituated to things, and they sometimes do it almost without consideration.

5357. But you consider that they suffer seriously ?—Yes ; all miners' lives are shortened by working in such foul air.

5358. The miners' lives you consider are shortened?—I have no doubt of it, that has come under my observation. I have observed it very particularly. I have seen the lives and health of the tributers much better than of the tut-work men, because the tut-work men are driving on to the extreme points to a winze or shaft, perhaps. Then when that is done the tributors come in and explore the ore above that level, and a current of air is kept up there ; consequently, the lives and health of the tributers, it has been ascertained, are much better than those of the tut-work men.

5359. Do you think that many of the men prefer tribute work on account of the air, besides the chance of getting more money ?—I do not know that ; some are more enterprising than others ; there is more chance of success upon tribute.

5360. How long should you say that men would go on driving in bad air to reach a winze or a shaft ?—It varies very much ; sometimes we have to drive 40 or 50, and I have known 60 or 70 fathoms to reach a winze or another shaft.

5361. Would it take five or six months ?—Yes ; it might take twelve months in some hard rock.

5362. So that men might be driving twelve months in poor air ?—Yes it is very possible, and not only possible but very frequently the case.

5363. You know that ?—I know that to be the case, and every miner knows it to be the case. Sometimes levels are driven on so far that they cannot go any further, unless they have some means to drive air. Then they are obliged to put in some fan or something of the kind ; but if that was only provided in the early time it would not cost more than at last, so that men have suffered a great deal, and have lost their labour through the want of such an appliance, and it sometimes has been obliged to be used afterwards.

5364. So that in those cases they only put in because men cannot work any longer ?—That is generally the case ; in some cases the captains are otherwise.

5365. It depends upon the captains ?—Yes.

5366. It varies according to the captains ?—Yes ; some captains have no thinking powers ; they do not regard the health of the men. But I have long argued that there is no reason for men to work in a close, dense atmosphere, and that a little artificial means might be used.

5367. And you think that by that means the health of the miners might be improved ?—I am sure of it.

5368. Do you not think that if the captains had a better education, it would be advisable so as to know something about ventilation, beyond the mere driving of an end ?—No ; I do not think that education would assist them there. Education is a very good thing, I am sorry that I lack it. I never had any since I was six years of age, and I should be glad if I had a little more, but I do not think that it would have made me a better mechanic than I am now.

5369. If the captains knew the evils attendant on bad ventilation, do you not think that they would be more ready to adopt means to improve it ?—No ; I do not think that education would give them anything more like a human feeling.

5370. (*Mr. Fulke Egerton.*) You think that they know that the air is dangerous ?—Yes ; they know it.

5371. (*Chairman.*) I suppose being strong men themselves, and not having suffered, they think that others will not suffer ?—Sometimes for the sake of the expense perhaps they will hesitate, and sometimes men will go on themselves and the candle will burn tolerably well ; but then the air is not so good as it might be, and it could be made better, and if men do not complain the captains do not give it the consideration which they should do.

5372. If men complain, do you think that the captains always provide means ?—I should expect that they would ; but in many cases there is poor air and the captains know it, and it is not remedied as it should be.

5373. And you know that of your own personal knowledge ?—I know that that is the case.

5374. You have examined different mines ?—I am called on frequently to inspect mines.

5375. And you have found that to be the case on inspection ?—I have found that to be the case. I have very often said to captains, "I should put in some fan or some pipes, or do something to convey air to the men." They say that the air is good ; that

ST. AUSTELL.
Capt. J. Webb.
22 April 1862.

it is not so very bad. I say, "You must have it by and bye, and why not have it directly." Then it goes on still in that way, it is not done as it should be. These are facts, and the miners suffer from it, and I have been long arguing or contending with parties that it should be done.

5376. And yet you know many cases where they have not adopted it after you have spoken to them?—Yes.

5377. Are the powder smoke and the candle smoke injurious to the men?—Very injurious.

5378. Can they be removed also by proper ventilation?—You can improve the wick of candles very much. There is a sort of slovenly stuff like hemp often employed in the wick of candles which gives off a cloud of smoke with it.

5379. That is well acknowledged, is it, namely, that a quantity of hemp will produce more smoke?—Yes; I think that I have a bit here now. (*The witness produced a candle.*) There are two wicks of that candle cotton and two hemp.

5380. And the hemp makes it create a great smoke?—Yes; if you were to light that candle now you would see a large cloud of smoke from it. [*The candle was lighted, and was found to produce smoke.*]

5381. Is that occasioned by the amount of hemp in the candle?—That and the amount of heat under ground. Carry two of those candles into a small space six feet high, and you will see what a smoke they must occasion.

5382. Are there candles made which will not give off so much smoke as that?—Yes; Palmer's candles of London—patent candles—which we have been consuming for years. They are made with a wick which gives no smoke.

5383. And will that answer in a mine?—Yes; miners like them after a little while.

5384. You have used Palmer's candles in your mine?—I have used them for years for the sake of doing away with this smoke.

5385. Is that smoke occasioned by the wick or by the bad tallow?—I think that it is from the wick.

5386. You find that the men in your mine are satisfied with the candles?—Yes, they like the Palmer's candles better; but I should think that you might put the same wick with this kind of tallow as Palmer uses.

5387. Where did that candle come from?—These candles are made by the merchants in this neighbourhood. The candles generally are of this kind in our mines.

5388. What is the difference of price between Palmer's candles and those candles?—I think that Palmer's candles are 3*d.* per dozen pounds more than these. We buy them at per dozen pounds.

5389. What is the cost of a dozen pounds?—It varies a little according to the tallow. I think that these candles now are 6*s.* 9*d.*, and that Palmer's candles are 7*s.* per dozen.

5390. Do you charge anything extra to the men?—We charge the men generally a penny a pound more than the candles can be bought for from the merchants. In some mines they charge 8*d.* when they do not give but 6*d.*; in some mines they charge 7*d.* They generally charge about 1*d.* a pound more.

5391. They charge the men 1*d.* a pound more than what they pay for them?—Yes, generally throughout the county. This is a thing which has hardly come under anybody's notice; but I have been long making my observations upon it, and saying what a nuisance it is in a small place where there may be two or three men working with two or three candles, and this dense smoke is going away in a small place. I used to take two of those candles, and go into a small room, and light them up on the table for about half an hour, and it was almost suffocating.

5392. Do you think that the men who work under you are more satisfied with your mine, and that they prefer it?—They prefer Palmer's candles after they know their value.

5393. With respect to blasting, how do your men fill the hole; do they put the powder in cases or not?—The general system of blasting in the county is to put the naked powder into the rock; but some captains say that the men shall use a case of paper or some other kind. That is the only safe way.

5394. You recommend a case?—By all means.

5395. Does not the hole require to be bored larger when there is a case?—No.

5396. The case must take up so much of the hole; so much less powder can be put into the hole?—You can put it firmer, more solid, and closer into a case than into the hole, unless it is driven in by a bar or something of that kind, which some men will do wilfully, and blast themselves by it.

5397. Will the hole contain the same quantity of powder if it is in a case as if it is not in a case?—I have tried it, and it will contain more, because you can put it in firmer. I have a case in my pocket. I have been studying that matter for years, and I now make all my men use cases.

5398. What do you charge them for those cases?—The price varies. (*The witness produced a case.*) It is prepared waterproof cloth.

5399. What is the cost of a case to the men?—That size would be about 12*s.* per hundred; in fact it is my patent. I took out a patent some time ago for it, and a great many of them are used in the county. There is a wadding of cowhair as a protection for the case and a foundation for the tamping.

5400. That prevents the danger?—That prevents the danger; there never is any. You never find an accident if the men will use those cases. I make some cheaper ones than that for dry ground.

5401. Those are for wet ground?—Those are perfectly waterproof.

5402. Do you think that the reason against the men using them is the price?—Some have objected to the price; but I contend that it is cheaper, because less powder will do; it will keep thoroughly dry, and if the powder is put into a rock where it is damp, without a case, it will destroy more powder than the case will cost, and damp powder will make a considerable deal more smoke.

5403. So that you would recommend the cases to be used for the safety of the men?—Those, or some cases; I prefer those, but they are my patent.

5404. For the safety of the men, you think that powder should always be put into a case?—Yes. The hole should never be blasted unless there was a case for it. I have known scores of accidents in my day from the want of it.

5405. Have you ever seen any cold damp in a mine?—Yes. I have seen it so that if you put a candle into it it will go out in a moment, the same as if you put it into water.

5406. Is it generally below or above the level?—Generally above.

5407. (*Mr Holland.*) Generally in the higher part of the level?—Yes.

5408. (*Chairman.*) Do you know what it arises from?—I suppose that it is from the dense fumes; we call it the damp.

5409. Cold damp?—Yes.

5410. It is your opinion that the health of the miners would be considerably benefited if the mines were properly ventilated?—Yes.

5411. Is bad ventilation, in the mines which you have visited, more general than good ventilation?—No. I think that there are more men working in good average air than in bad. It is at the extreme points that it is bad.

5412. Then it is your opinion that there are many ill-ventilated ends?—Yes.

5413. (*Mr. Kendall.*) You have had the management of a good many mines in this neighbourhood, have you not?—Yes.

5414. What are they?—The first mine that I managed in this neighbourhood was the Great Polgooth, then the Great Hewis.

5415. How long did you manage the Great Polgooth mine?—Two years, after Mr. Bell's death.

5416. Did that mine cease after that?—It came into other hands.

5417. And then it came into the hands of another agent?—Yes.

5418. Then you went on to Hewis?—Yes.

5419. Did you manage that for some time?—Seven years.

5420. And did it then fall into other hands?—I was there as long as it was worked; till it was abandoned.

5421. Where did you go then?—I had the Great Crinnis mine at the same time.

5422. Did that also pass into other hands?—Yes.

5423. With regard to ventilation, where there is defective ventilation, does that occur more in small and new mines, or in large mines?—I do not know; it varies very much.

5424. Have you been called in lately to see any extensive mine, to report on it?—No, not for the last two or three months.

5425. Have you, within the last year, seen any old workings?—Yes, many times.

5426. Do you think that it is more frequent in old mines?—Yes.

5427. In old mines is there much decayed material—much decayed wood, or anything of that kind?—Yes; I have known several mines where the wood has been decayed, and the atmosphere there has been very bad indeed. I think that all the dry levels should be pitched or tarred underground. It would be worth while to do so for the preservation of the timber, and I do not think that then that matter would issue from it.

5428. In any of the mines which you have visited do they use air sollers?—Yes; that is frequently done.

5429. Does it answer?—Yes, when you can get a strong current and a trapdoor, as we call it, to throw it into that soller instead of above.

5430. You think that that is a good mode of ventilation when you can apply it?—Yes; but we cannot always apply it. We must have a strong current of air to apply it; because if you confine the air under a soller it will be contracted, and it will not travel so easily unless there is a strong pressure.

5431. Have you ever seen any other artificial means of ventilation besides the air fan, the water, and the soller?—Yes; we have sometimes put in a piston when we work it by the engine, but we cannot always bring it to bear when we are at a distant point from the engine.

5432. But if it is near the engine you can throw in a good flow of air by that means?—Yes; you can put in a piston.

5433. Have you inspected any mine hereabouts?—Yes, I have inspected a mine down here, 180 fathoms deep, several times in the last year.

5434. Did you see bad ventilation there?—No; the ventilation was good there.

5435. Have you inspected any deep mine lately—within the last 12 months?—No; not within the last 12 months.

5436. Where has the ventilation been bad which you have inspected?—In most mines that I have inspected, when the ventilation has not been generally bad throughout, there have been ends driving or winzes sinking where the air has been very bad in many points.

5437. Can you state a case, without mentioning the mine, where there has been bad ventilation?—It has come under my observation several times, and I do not know any particular place.

5438. Will you state some mine, at some depth, where there has been the driving of an end, within the last two or three years, which you have been called in to inspect?—There is a mine which I have inspected for the last 20 years. I have observed that there have been ends or distant points where men have been working in such air as I have been speaking of. I have observed it many times in that period, and in my own mines I know that it is the case if I do not apply some machine.

5439. Take the last four or five years. Will you state one or two of the worst cases where you have remonstrated, and have said that the men were working in very impure air?—In almost every mine, if the levels are about 20 or 30 fathoms from the shaft, I always observe that the air is not fit for the men to work in.

5440. Have you observed that more in small mines or in large mines?—It is possible to have the air as bad in a shallow mine, not more than five fathoms deep, as it is at 100, or 130, or 140 fathoms.

5441. Have you observed it most in those small mines or in the large and deep mines?—In both. I always observe, that when the end or gallery is 20, 30, or 10 fathoms off, the air is very close and very impure. Men must keep their candles down flat for them to burn, and I have seen men working when the grease has been running down from the wick.

5442. Do you think that agents and men are as careless now as they were 20 years ago in those mines?—Yes; I do not see much difference.

5443. With regard to your mines, do you principally use fans or water-falls?—The fans are the most direct and easy to be applied where we cannot have water-falls. We cannot have water-falls in one place out of ten.

5444. Where you have a water-fall, can you apply that water-fall to rises as well as to ends?—If you have, say a 10-fathoms fall, there is no better or cheaper means that you can apply than a water-fall.

5445. If you have a supply of water, you can direct that water-fall not only in your drifts, but in the backs and where the tribute workers are, and so on?—Yes; anywhere.

5446. Have you not an improved water-fall by Mr. Williams in your mine?—I have worked one in West Par for a long piece of ground. We were sinking 90 fathoms from the shaft, and we did it by a water-jet; but there is not one case in 10 where you can apply that. We must have a column of water in the shaft and pressure.

5447. It is not Mr. Williams's patent, but is an improvement upon the old plan, is it not?—No, I do not think that it is any improvement. It was suggested by some person up in the northern part of England, who came down here and suggested it.

5448. How long ago?—I should think 4 or 5 years ago.

5449. But a water-fall was used many years ago?—Yes; but this water-jet and a water-fall are two different things. A water-jet will do with a great deal less fall than a water-fall. With the water-jet you may take in a small stream of water, and it will give a pressure.

5450. Take your patent case for a moment; since the use of that case in your mine you have had no accident?—Not any.

5451. Having a case for powder and having something round it which is waterproof, is not new. In what does your patent consist?—It consists in a cloth covered with any waterproof solution and with cowhair wadding upon it.

5452. I suppose the improvement is the cowhair wadding?—Yes; and the cloth. It has never been used in that form; paper has been used and pitch for many years, but cloth covered with waterproof solution was never used before.

5453. That is the patent?—Yes.

5454. I suppose that if you could make the men use it, the impalpable powder which they get from the mine would be almost as safe as cow hair, would it not?—Sometimes, if the holes are wet, if you put in the borings, it becomes almost like slime, it would not do in wet ground to put in those soft borings like flour.

5455. And this you find answer very well?—That is a foundation for tamping and that is a complete cure.

5456. Do you find it generally used or not?—

I have found a great many of them in the west, and in some mines in this neighhourhood they have had them for years, and the more the men use them the better they come to like them. Some of my men say, "We should be afraid, or should be timid, to use powder after using these cases." It is because men become so habituated and hardened to the thing that they do not think it dangerous.

5457. What is the cost of using your patent in the different mines ?—I merely supply the materials.

5458. At a price named by yourself ?—Yes ; I supply different sizes, and different lengths at different prices.

5459. (*Mr. Dovey.*) You said that some of the men objected to Palmer's candles ; can you state the reason for that ?—They objected at the beginning, but afterwards they liked them ; there was a little smell with Palmer's candles which they did not fancy at the beginning.

5460. Supposing there should be any accident and the candle went out, could they restore the light again and blow it up ?—No, they can never blow up Palmer's candles.

5461. And that is the great objection to Palmer's candles, is it not ?—I do not see any disadvantage in it. They always take lights with them; there is another man with them.

5462. Do you know why, in the candles to which you object, hemp is put with cotton into the wick ?—No ; but they have been accustomed to do so.

5463. Do you know that it is because the men can blow the candle up in case it goes out, and not be left in the dark ?—No, I do not think that it is for that purpose.

5464. You said that there was a profit charged by the adventurers on the materials supplied by them ? —Yes ; I do not know that it is always the case, but generally they charge the men a little more than they give the merchants.

5465. Do you know that the object of that is that the men shall not go and sell them to other people ? —Yes, perhaps that was the first object.

5466. (*Mr. Austin Bruce.*) You say that you have gone down to inspect a good many mines of late years ?—Yes.

5467. In what capacity did you go to inspect them ? —Perhaps I should have a letter from a gentleman asking me to inspect such a mine for him being an adventurer in the mine. Then I should go and inspect it and report to that gentleman who employed me.

6468. Taking one year with another during the last 10 years, how many mines have you inspected ? —I could hardly tell, I have inspected a good many in a year sometimes.

6469. How many did you inspect last year ?—The last two years my health has not been so good for going down in deep mines, and I have refused to go into some places, but in the last four or five years I have inspected a great number of mines, I do not know that I can give an account of the number.

5470. Cannot you give some sort of idea ?—I have inspected two or three mines in a quarter sometimes, and sometimes I have been a quarter when I have not had an inspection, and sometimes again I have been too busy to do it. I do not know that I can give you any definite statement of the number of mines which I have inspected.

5471. Have you inspected 20 mines in the last five years ?—Yes, and more than that I should think.

5472. Are you usually paid for your services ?—Yes.

5473. Is it a common thing for experienced captains to be employed to inspect other mines ?—Very common.

5474. Then most captains can speak as to the ventilation of other mines besides their own ?—Yes, if they are called upon to inspect mines.

5475. I asked you that question whether they usually were called upon to inspect mines ?—I hardly understand you.

5476. I ask you whether it is a common thing for captains to be called upon to inspect mines ?—Very common.

5477. (*Mr. St. Aubyn.*) When they were called upon to inspect mines, would they report on the ventilation unless they were specially desired to do so ?—No.

5478. (*Mr. Kendall.*) Are those 20 mines to which you have referred, which you have inspected, established mines or mines going into the market ?—Sometimes they would be established mines, and at other times they would be mines in the market.

5479. Out of the twenty mines which you have inspected in the last five years, how many were established mines ?—You may say 20 mines in 10 years. I know that I have inspected a great many mines in the county in the last few years. I have been connected a great deal with mining gentlemen, and I should receive a letter saying—"Will you inspect such and such a mine for me, being a shareholder," and I should inspect it, and report on it.

5480. (*Mr. Austin Bruce.*) Do you consider that at 30 fathoms from a winze, the air can be sufficiently good for a man to work in, without any artificial ventilation ?—I think that it should be improved if above 20 fathoms. Men may work at 40 fathoms.

5481. Have you ever known an instance in which a close end was worked at 30 fathoms from the shaft or winze without some stagnation of air ?—Yes, I have known levels more than 30 fathoms from any current of air, and a candle would burn well ; but when the men blasted, the dense smoke would lie where it was until they made another blast, and the place has been quite full of smoke from one end of the corps to the other, when the candles would burn moderately. Even then, I think that the air is too bad for the men to breathe, if it can be improved.

5482. Do you think that any place in which the powder smoke remains half an hour, can be a proper place for a man to work in ?—No ; he ought not to do so.

5483. Is it common for close ends to be driven 30 fathoms from a supply of ventilation without any artificial ventilation ?—It is very often the case.

5484. Am I to understand it to be your opinion that in all those cases artificial ventilation ought to be supplied ?—Yes, it would improve it.

5485. And that a man's health must suffer sooner or later from continuing to work in the air of such a close end ?—Yes ; if an end is 20 fathoms off and a little fan machine were put in, and three boys were employed to drive that fan, I believe that the men in the end would do more extra work than would maintain those three boys, besides the value of their health.

5486. You have been a working miner ?—Yes.

5487. How many years were you a working miner ?—I commenced working underground when I was about 15 years of age, and I worked underground until I was somewhere about 28.

5488. You were 13 years a working miner ?—Yes.

5489. During that time did you ever work in close ends ?—Very little.

5490. You were a tributer ?—Yes.

5491. Did you ever work in rises on backs which were ill ventilated ?—Very little indeed. I might for a few days just to hole a piece of ground, that is all.

5492. How came you to be more fortunate than many others who, according to your description must have been working in bad air ?—Because I was working on tribute generally.

5493. Could you choose your own places of working ?—No. I did choose, because I always refused to work in bad air.

5494. (*Mr. Kendall.*) You say that within 10 years (at first you said within five), you have inspected 20 mines ?—Yes, I say 10 years to be safe.

5495. Out of the 20 mines, how many do you think were established mines and how many were mines going into the market ?—I do not know that I could

answer that question. I have inspected various mines; they were of each class I suppose.

5496. As much one as the other?—Perhaps so.

5497. Then you would say that you have inspected 10 established mines. Were most of them in this county?—Yes. I have inspected some in Ireland and some in France, but in this country generally.

5498. What established mines in this country have you inspected; take a few of the most established?—I might call to my remembrance in a little while several mines. I could not call the whole to remembrance.

5499. Take one or two of the best?—I have inspected some in Gwennap, and I have inspected some in St. Just, and I have inspected some in Camborne.

5500. What established mines in Gwennap have you inspected?—I have been in the Henry mines and I know that there was a close place there; I have never been in the great mines, the United mines. I was never down those or the Consols.

5501. How many men were working in Huel Henry?—I suppose at that time about 40 men, that is 14 or 15 years ago; but I have inspected in Camborne and in St. Just.

5502. What mines in Camborne have you inspected?—I have inspected the Roskea.

5503. Which Roskea?—South Roskea.

5504. How many years ago was that?—It was several years ago. I do not know how many; perhaps 10 or 12 years.

5505. Has not that mine stopped for nearly 20 years?—No.

5506. For how many years has it stopped?—I should not think more than 10 years; it may have stopped 14; I cannot tell.

5507. What other established mines have you inspected?—I can hardly call them to remembrance. I could give them to you upon paper.

5508. What established mines at St. Just have you inspected?—I have been down the Levant mine.

5509. You went to inspect and report upon it?—Yes.

5510. How many years ago?—Several years ago. I have inspected a great number of small mines; I have been in the great Beam mine.

5511. Was not that one of the worst mines that we have ever had in the county of Cornwall?—Yes, I suppose so.

5512. What established mines in the west have you inspected in the last 10 years?—I have been in the Trevenen mine.

5513. What parish is that in?—In Wendron.

5514. How many men were working there when you inspected it?—I should think there were somewhere about 50 or 60 men perhaps working then.

5515. What depth was it?—170 fathoms.

5516. How was the ventilation there?—The ventilation was tolerably good. I have observed that the air has been as bad in close places in shallow mines as in deep ones.

5517. What particular shallow mines do you refer to now which you have inspected?—I can give you a list of a score, I suppose, if I go home, and just go through my pocket book and see what mines I have inspected, but I could not call them to remembrance now.

5518. In fact your inspection has not been much the last 10 years?—Yes, it has. I could give you a great number of mines that I have inspected in 10 years.

5519. (*Mr. Davey.*) Did you make reports for prospectuses when you inspected the small mines; were they published at all?—I made out my reports for those who employed me.

5520. But were they published as a prospectus afterwards?—Yes; I have seen my reports to a prospectus many times.

5521–48. Was not it principally for that purpose that you were employed?—I do not know that it was principally, but I have been employed on some occasions.

The witness withdrew.

Adjourned to to-morrow at 12 o'clock, at Par Consols mine.

Wednesday, 23rd April 1862.

REFORM CLUB
PALL MALL

PRESENT:

The Right Hon. Lord KINNAIRD, K.T.
The Hon. A. FULKE EGERTON, M.P.
NICHOLAS KENDALL Esq., M.P.
P. H. HOLLAND Esq.
H. AUSTIN BRUCE Esq., M.P.

The Right Honourable Lord KINNAIRD, K.T., in the Chair.

MR. WILLIAM PETHERICK examined.

5549. (*Mr. Kendall.*) What age are you?—58.

5550. How early in life did you begin mining?—In 1817.

5551. Since the year 1817 you have been connected with mines?—Yes, but principally from the year 1820. I was in the West of Cornwall employed underground as a boy, then I came here, and went underground here.

5552. You were employed as a boy, and worked your way up?—Yes.

5553. You came to this place in 1820 as agent?—I was at Landiscot Mine before.

5554. What depth was that mine at the time you went there?—Very shallow; about 20 fathoms.

5555. How deep was that mine when you left it?—She was in 1834, I think, 140 fathoms.

5556. During the years that you were there was the ventilation generally good or bad?—It was always very good, except in a little way from the ends where the winzes were not communicated.

5557. How far used you to drive before you communicated with the winzes?—Perhaps about 30 fathoms.

5558. Have you known bad air there?—I have known bad air there occasionally for days.

5559. Did you ever see any difficulty as to the burning of candles?—Sometimes, but not very often.

5560. Were you obliged to put the candles in an inclined position to make them burn?—Yes, occasionally, in the close ends.

5561. To the best of your recollection, how many close ends at one time were they obliged to work in that way?—Perhaps five or six.

5562. In those cases the men, I suppose, suffered?—Yes, some little; sometimes it was owing to the stuff not being taken away.

5563. There was so much stuff in the end that they were overcrowded by it?—Yes, it was so, sometimes; and very often that occasioned a close atmosphere.

5564. What was your experience as to the health of the miners while you were there?—They were generally very healthy.

5565. I believe there was no dry there then?—They just had one, before I started; I think so.

5566. What has been your experience as to the miners; were they as strong as the agricultural laborers?—They were shorter lived, and not so strong.

ST. AUSTELL.

Mr. W. Petherick.

23 April 1862.

5567. Did you attribute that to the nature of their occupation, or did it principally arise from the bad air?—The nature of the occupation, I think, has been a great detriment to the miners, and climbing.

5568. The man-engine had not been introduced there when you came away?—No. I recollect going up from 140 fathoms deep, and when I got within 50 fathoms of the surface I would as soon lie down and remain there as go up, I was so exhausted; that principally arose from the inclined state of the ladders; they were inclined in that way that the weight rested upon the chest and head.

5569. Although you have constantly ascended and descended a mine, still you never ascended without feeling considerable fatigue after mounting a certain number of fathoms?—Always great fatigue; it was so at 100 fathoms.

5570. And that would increase as the mine became deeper?—Yes.

5571. What other mines have you been in since that time?—I went from Tower Consols to a small lead mine in the north of Ireland, county of Armagh.

5572. Did anything strike you upon the subject of ventilation there?—No; it was very good there; the mine was shallow.

5573. There you had natural ventilation?—Yes, always.

5574. What mine after that did you go to?—I went into a colliery in the county of Tyrone, and we drove, I suppose, 100 fathoms without any shaft; there was no communication with a shaft.

5575. How did you manage there?—Just as you do here, by levels being driven, and another communication by winzes all the way along.

5576. In the different beds of coal?—Yes.

5577. You went from one bed to another, and ventilated in that way?—Yes; with air courses.

5578. Therefore the ventilation of coal mines must of necessity be very different from that of copper mines?—Yes. The advantage of copper mines is, that you communicate by the winzes to the surface; and in coal mines you have a receptacle for all the gases called goafs, which is not relieved but for a certain distance, and beyond which they cannot have it; but here 140 fathoms is the greatest distance from a shaft. The shafts are often 100 fathoms apart only; some 50.

5579. Can you speak of any other mines that you have been in?—A colliery in the state of Pennsylvania, and there we worked to a great depth, and went the length of a quarter of a mile without a shaft.

5580. How did you manage the ventilation there?—In the same way as here. Having got to the surface, we put up an air course.

5581. (*Mr. Austin Bruce.*) Had you a furnace there?—Yes; and when we went up we communicated in this way (*describing the same*), and then the air course came back to the level.

5582. Over the furnace?—Outside, until we got in sufficiently to drive up the mountain. It was a level.

5583. Have you been inspecting any copper mines in Cornwall during the last few years?—No; I have never been underground. I have been down through Cornwall making inquiries.

5584. Have you had any experience at all with regard to the ventilation of copper mines any where besides?—No, I have not; only here.

5585. Have you had any experience in America?—No; I have in the native copper mines on Lake Superior.

5586. The means of ventilation there used would not be applicable here, would they?—I do not know. The air is much lighter in the summer time. The air will rush in with great rapidity in the levels; 400 feet in a minute in the winter time; and in the summer time it will rush down, and come the contrary way.

5587. The upcast and the downcast are different?—Yes; in summer and winter.

5588. As I understand you, in some part of the year in one shaft it is an upcast, and in another part of the year it is a downcast?—Yes; the mean temperature inside is about 60° in the winter time, when the thermometer ranges from 40° above zero down to 35° below; then it rushes into the level, and goes up 200 feet high, and where the workings are perhaps 2,000 feet long. In summer time, when the temperature ranges from 75 to 95, then the atmosphere is so heavy below that the heat rushes down, and destroys the ventilation, as it cannot escape through the shaft.

5589. When at Fowey Consols did you observe any difference between the winter and the summer?—In summer time it was hotter, and there was a little closer ventilation, and it neceesarily will be so.

5590. Acknowledging, as you do, that the miners are not so strong as agricultural labourers, do you think that they suffer more from climbing or from bad ventilation?—From both combined; but I think principally from climbing.

5591. Take bad air as one element; then, as against bad air, put climbing, want of proper accommodation for men to change their clothes in drys, and their sleeping in crowded rooms; which do you think does the most damage to the miner?—I think that very often the want of accommodation on coming to the surface militates against the health of the miner very seriously.

5592. Do you think that the climbing, and the bad accommodation for changing their clothes when the men come up warm, and the bad ventilation which very frequently arises from over-crowded rooms, are not more injurious to the miner than the one element of bad ventilation in the mines? Yes, I think they certainly do amount to more than the bad ventilation in the mines. The Commissioners may perceive, upon this plan, which represents the mining generally throughout Cornwall, that the ventilation is perfect almost to the ends.

5593. (*Chairman.*) Have you studied medicine?—No.

5594. Have you ever examined the men on coming up from the mines?—No.

5595. Then upon what is your opinion founded?—It is from my own feelings.

5596. You have stated that in this mine there are five or six bad ends. How many men are working in each corps?—Six; sometimes four, and sometimes there are eight.

5597. Then there would be about 36 men working at one time in bad ends?—Yes; but that is very often temporary. I wish to draw your Lordships attention to one point. That part of the mine would be perfect (*pointing to a plan*) if there were a communication with the air; owing to the levels being driven here (*pointing to the plan*) the communication is perfect all the way up here (*pointing to the plan*); but then here, before this communication (*pointing to the same*) was made, possibly there would be bad air for two or three months before the communication was made, and then it would be so perfect that the air would rush through.

5598. Has the longest time you have ever known the men driving in an end before the winze was opened been three months?—Yes; in inferior air.

5599. Have they never driven more than three months in inferior air?—Not on veins. I am speaking generally. There might have been one case in a year. I was there for 17 years.

5600. During that time was there only one case within your knowledge?—They have never been more than three months working in bad air.

5601. During the whole of those 17 years?—Yes; at a time.

5602. (*Mr. Kendall.*) How happened it that they were for so long a time as three months?—Sometimes the stuff could not be brought away from long distances; a great distance from the whinze would be another cause.

5603. In driving an end, or in driving before a winze has been opened, the men have never driven for more than three months?—They may not drive

for three months in bad air; not for more than a month.

5604. But never for more than three months?—Not to my knowledge.

5605. *Mr. Austin Bruce.*) How soon do you think that the air becomes bad after the miners get into a close end?—It may be a month or two.

5606. After driving for a month or two?—Yes.

5607. How do you judge of the presence of bad air?—We can tell by the state of the candles.

5608. Have you anything else to judge by?—Our feelings.

5609. Does the unpleasant feeling begin some time before the candle shows any sign?—I think not.

5610. Do you think, therefore, that the men may work healthfully in a close end up to the time that the candle begins to fail in its light?—A man may so work for a short time.

5611. But would you say that he might work up to that time, or do you think that a man could work, even for one week continuously, as a miner works, in close air, without being, in the long run, the worse for it?—He would not feel a great deal of it in a week; he would in a month.

5612. At the end of a month he would feel probably rather weak, as compared with what he was at the beginning of the month?—Certainly.

5613. But without feeling either weak or ill, do you suppose that a man can frequently work in bad air without its affecting his constitution?—Certainly not; he must feel it.

5614. Is not that the probable cause of the shorter life which is generally attributed to the miner?—No. I think the climbing and the bad accommodations are another great cause.

5615. Do not you suppose that the effect of climbing is much more marked and severe upon the man who has been working in tainted air?—He would feel it rather more.

5616. Suppose that the powder smoke were to remain, after the shot has been fired, for half an hour in a close end, should you consider that a proper condition of the atmosphere for the men to work in?—No.

5617. Does it not frequently happen that the men do work in close ends in which the powder smoke remains for half an hour?—Not frequently.

5618. But does it not occasionally happen?—Yes, unavoidably.

5619. You mean unavoidably, I suppose, unless artificial means of ventilation are introduced?—You cannot drive a level beyond a winze but what you begin to feel the want of ventilation a little.

5620. In that case, the want of natural ventilation, I suppose, can always be supplied by artificial ventilation?—It is supplied in many cases, wherever it is wanted.

5621. Then will you explain your meaning in using the expression "unavoidably?"—You cannot always at first apply artificial means.

5622. You have spoken of what you suffered in climbing?—Yes.

5623. Are not those sufferings very often much aggravated by the fact that you are climbing in the upcast instead of the downcast?—No, I think not. I do not think there is much difference.

5624. The upcast air must be heavy and tainted?—Yes.

5625. Do you mean to say that to breathe the upcast air in 100 fathoms would be no worse than to breathe at 100 fathoms down the downcast, when you would meet the fresh air coming from the surface?—Certainly, it would be worse.

5626. On some occasions the climbing in the upcast must be very severe, apart from the mere labour of climbing?—Yes; but you must not suppose that all the shafts they climb up are upcast shafts.

5627. But the shaft is sometimes upcast, and sometimes downcast?—Yes.

5628. If you so managed your ventilation, as in coal mines, as to make the upcast always an upcast, and the downcast always a downcast, you might have more of the climbing take place in the downcast shaft on all occasions, might you not?—That depends upon the state of the atmosphere.

5629. No. if you managed your ventilation as it is in coal mines, so that the upcast should always be the upcast, and the downcast always the downcast, you could then confine the place where the ladders were put to the downcast?—Sometimes it would be so, and sometimes not. Sometimes we have seen the downcast go one way and sometimes the other.

5630. I am aware of that; but if you so contrived the ventilation as to send the return air uniformly up one shaft, so as to make that the upcast, and the ladders were put in the downcast, that would be a great advantage to the miners, would it not?—That is true.

5631. Is there any insurmountable difficulty in so directing the air that the downcast shall always be the downcast, and the upcast always the upcast?—I think that it cannot be directed with any thing like certainty.

5632. By means of natural ventilation?—No; it is not like coal mines; you are always changing your cast here.

5633. You do not think it worth while to imitate the coal mines?—I do not think it would be; I do not think it could be carried out.

5634. (*Mr. Kendall.*) I suppose it could not be carried out because there are so many shafts?—Yes; you are always altering.

5635. Would not the quantity of tainted air in the upcast shaft be very small as compared with the quantity of pure air in some of the shafts?—Very small indeed; you are always coming in contact with the levels coming out of the shaft.

5636. Therefore, I presume that the miners would not be so much affected by the tainted air in the upcast shaft?—No.

5637. (*Chirman.*). If there are only two shafts, or only one shaft, in a mine, would not the quantity of poor air and powder smoke be greater than where there are many shafts?—Certainly, vastly greater.

5638. So that if there were two shafts, and the impure air was coming up one, you would sensibly feel it?—Yes, that would be the case.

5639. Must not the length of time during which the men would be driving through poor air depend upon the material they had to drive through?—Yes; whether it is hard or soft ground.

5640. Where the ground is hard, would they drive for a much shorter distance?—You must always drive to your object.

5641. Therefore the length of time in which they might be driving an end must depend upon whether the ground was hard or soft?—Yes.

5642. (*Mr. Kendall.*) Can you explain to the Commissioners why, in working through different strata in different localities, the air is, sometimes, in an end, ten fathoms off from a winze, twice as bad as in other localities 30 fathoms distant?—They always vary.

5643. So that you never exactly know how far it is necessary to make your artificial means of ventilation extend, judging by the candle, according to your present practice?—No.

5644. (*Mr. Holland.*) Have you seen many coal mines?—Not many; I have seen very large ones in Pennsylvania.

5645. Have you seen any in Durham?—I have never been there.

5646. Or in Yorkshire?—No.

5647. Do you know that coal mines are better ventilated than copper mines?—I do not think that they are so well ventilated as copper mines.

5648. Not, generally speaking?—Generally speaking, I think that the copper mines are the better ventilated.

5649. Is it not the fact that there are great currents of air in coal mines, at something like ten miles an hour?—Yes.

5650. Is that so in copper mines?—Yes. There is a cross-cut in this mine, particularly if you blast a

St. Austell. Mr. W. Petherick. 23 April 1862.

hole at one part of it; you could not follow the smoke to the other, it would go faster than you could.

5651. But is that a common thing in your mines?—Yes, very often; it rushes at the rate of 400 or 500 feet a second.

5652. Throughout the levels, generally?—Yes. The foul air that I have alluded to is only in short distances before they communicate with winzes. There are 800 miners altogether, and 400 of them are tributors, and, generally speaking, they are working in perfect ventilation; you will see that. Any of the remaining 400, I suppose there are three-quarters of them in very good ventilation; they are sinking winzes and driving levels.

5543. (*Mr. Austin Bruce.*) Then seven-eighths of them would be in good ventilation?—Yes.

5654. (*Mr. Holland.*) Granting that there is a good draught in the mine, unless that draught goes right through the mine, down one shaft and up another, may it not be a changing about of the same air; not fresh air?—The bottom part of the mine will be necessarily warm; it will be very fair, but changing; as you come upwards, it will get cool.

5655. (*Mr. Kendall.*) Did you not drive a long adit at Kedmore?—Yes, 220 fathoms; and by means of a waterfall the air in the end was as good as the air in the shaft.

5656. Do you not think that the men might be sent up and down from the mines in skips?—I think so.

5657. Have you seen them in use?—I have; I have used them myself, at small depths; still I know it is practicable.

5658. But your experience is not very great in that matter?—No.

The witness withdrew.

Adjourned to Callington, To-morrow.

Thursday, 24th April, 1862.

PRESENT:

The Right Hon. Lord Kinnaird, K.T.	John St. Aubyn, Esq., M.P.
The Hon. A. Fulke Egerton, M.P.	Richard Davey, Esq., M.P.
Nicholas Kendall, Esq., M.P.	P. H. Holland, Esq.
H. Austin Bruce, Esq., M.P.	

The Right Honourable Lord KINNAIRD, K.T., in the Chair.

The Commissioners took the following evidence at Redmoor Mine.

Captain Thomas Taylor examined.

Capt. T. Taylor. 24 April 1862.

5659. (*Chairman.*) What kind of ore do you produce here?—Tin generally; tin and copper mixed.

5660. About how many men have you employed underground?—About 40.

5661. You have only charge of this one mine?—Only one. We have another small mine below, but it is not of much importance as yet.

5662. What is the depth of the mine?—One hundred and twenty fathoms. We are only working at the 80 fathoms; the shaft is 125 fathoms.

5663. In what manner do the men ascend?—By ladder.

5664. How many ends are you driving now?—We are driving only two now.

5665. I suppose you have no hot end?—No.

5666. Are there any ends where the air is poor at all?—No; we have very good air here.

5667. How soon does the powder smoke clear away?—It depends partly on the state of the atmosphere. Just as the wind is now, it is scarcely any detriment at all to the men; the hole is no sooner blasted than the smoke goes off, almost at once.

5668. How many shafts have you?—Four.

5669. Is there one up-cast and one down-cast particularly?—Yes.

5670. Do they change at all?—Sometimes they change; it depends upon the way of the wind. If the wind is from the east, it blows down through this shaft (*pointing to a plan*), and if it is the other way, it goes the other way and comes up through the other shaft. But that current is only as far as the 40 fathoms; below that it is always in one way.

5671. Which shaft is the upcast from below that?—The engine shaft; the lower one. Then it comes up, and there is a cross-cut; then it changes as the wind changes.

5672. But below the 40 fathoms it is always the same?—Yes.

5673. When you are working below the 40 fathoms, does the powder smoke not hang at all?—Very little; it is scarcely anything; it is what you may term very good air. Of course it is not as clear as it is at the surface.

5674. In summer, when there is no wind, does the powder smoke hang for a quarter of an hour, so that the men are obliged to leave it?—No; we could go to work within a quarter of an hour at either end that we have got. We have three ends; one is a cross-cut. We have two ends driving on the lode.

5675. Have you any boys employed below?—Yes.

5675*a*. What are they employed in?—There are two employed in wheeling the stuff; they are from 16 to 20 years of age.

5676. Are there any younger than that?—No; not underground. I believe that one or two of the tributors have their boys with them; they are perhaps from 14 to 16 years old; the fathers take them down with them.

5677. Have you had any accidents from blasting within the last four or five years?—No; we never have had one; we have been very fortunate. We have had one arm broken, and that is the greatest thing that we have had in these 12 years.

5678. Have you any rules as to blasting which you make the men observe?—The rules are, that supposing they should what is termed miss the hole, and it should not explode, they are not allowed to go to it for their corps; and if they should bore a hole and it should not throw out its burden, but crack out, I compel them to put clay in it and fill up the crack, so that no powder shall lodge in it.

5679. When it does not go off, do they bore another hole afterwards?—No; they let it remain, perhaps, for six or seven hours, and they take what is termed a picker and pick it out. They keep the hole full of water.

5680. Is the picker iron?—Yes. When they get down to what is termed the first laying, the laying on the powder, it is then very easy to come up.

5681. Do your men reside at a distance from here?—In Callington chiefly; it is not more than half a mile. I think there are one, or I think two, who may perhaps be a mile and a half.

5682. Have you any men that you know of working who are at all affected in their breathing?—No; I do not know that we have any. There is one who is now home. I do not know what is the matter with him; he is affected in the heart or something; but I do not know that it is occasioned by working under ground.

5683. Was he working with you for a long time?—No; not more than about six months.

5684. Did he come to you with that affection?—He never complained of being injured in the mine at all.

5685. But he has left work now?—Yes.

5686. Where does he reside?—At Callington. I do not think that he considers that he has been injured under ground. I never heard him say so.

5687. Have you a dry?—We have a changing-place close to the blacksmith's shop. Ours is not a wet mine, it is very dry; there are hardly any wet clothes at all. Then we have a fire-place in this changing-house; they do not throw their clothes on a sort of tube, it is not required here; they change their clothes near the blacksmith's shop.

5688. (*Mr. Kendall.*) You say you are driving two ends?—We are driving three ends, but two are on the course of the lode.

5689. You are driving two ends and a cross-cut?—Yes.

5690. What is the deepest level at which you are working?—The 80 fathoms.

5691. How far is the 80 fathoms end from any winze?—About 4½ fathoms, I suppose.

5692. Not more than that?—No; I do not think it is at all more than that.

5693. How far shall you most likely drive before you communicate with another winze?—We can hardly say that; much depends upon the working of the end. We have a cross course now close to the end, and very likely we shall run on from there up to the 70 fathoms.

5694. Generally speaking, in driving that level, how frequently have you had winzes?—We have had six winzes.

5695. In what length?—I suppose that that is very nearly 70 fathoms off from the shaft. As the end goes on, the end is put down here (*describing the same*), and pieces are put in here, and the air passes right along, and that serves as another winze, and we get equally good air.

5696. How far do you generally drive before you find it necessary to sink a winze there?—It depends more upon the nature of the air that is out. If you are coming away from a shaft, you can drive a great deal farther than otherwise. It all depends upon the current of air.

5697. Do you ever go beyond 30 fathoms?—Yes; many ends have been driven beyond 30 fathoms. Some of the ends are driven 40 and 50, and one as far as 60 fathoms, and there is capital air in that end now; and it is 60 fathoms from any communication.

5698. Is there any brattice at all?—No; nothing at all but a simple drivage. There is no stall whatever.

5699. Are there any sollers?—No; there are two levels.

5700. Are the backs worked away at all?—No.

5701. It is a simple drift, how high?—About seven feet.

5702. And how wide?—About four feet. The width of an end you can hardly tell.

5703. You have gone more than 50 fathoms from a winze, and the air is very good?—Yes.

5704. How long after blasting can the men go in?—Within a quarter of an hour, without feeling any effect.

5705. (*Mr. Davey.*) Is that from a winze, or from a shaft?—From a lead lode. There is a regular storm of wind going through the lead lode. The draught comes this way (*describing the same*). I do not know an instance where you could drive again with as good air. I never saw it like it.

5706. Is it in granite here?—No; in clay slate or killas. There are two shafts on the lead lode, and the ground is nearly all worked away on this lead lode.

5707. (*Mr. Kendall.*) The air is taken from a drive between two shafts?—Yes.

5708. (*Mr. Austin Bruce.*) How far is that drivage from the end which you are working; how far is that end from the fresh air?—About sixty fathoms.

5709. Is it hot there?—No; I have heard the men in the mine say, that they do not know such an instance anywhere.

5710. (*Chairman.*) Are they working at that end now?—No; that work is all abandoned now. There is plenty of air.

5711. (*Mr. Kendall.*) Is it a rare instance?—Yes.

5712. (*Mr. Holland.*) Is that all in granite?—In killas granite.

5713. Is it much the same through the whole length of it?—Yes.

5714. What did it cost a fathom when you began?—I think we gave 4*l.* a fathom.

5715. What does it cost you now?—About 4*l.* a fathom.

5716. Does it cost you the same as when you began?—Yes, with the addition of the wheeling; the ground is much the same; we give more for bringing out the stuff.

5717. There is no deficiency is there?—No; there is no deficiency as to the state of the air.

5718. (*Mr. Kendall.*) As I understand, the only cost now at the end of the sixty fathoms is the labour of taking back the stuff from that end?—Yes; I believe we can drive the end as cheaply now as we could when we commenced.

5719. As far as air and other matters go it makes no difference?—No difference at all.

5720. (*Chairman.*) You are not working there now?—No; I would not say for a moment that you could drive another level much more than half as far. I do not know another such instance. We cannot drive such an end in the lower part of the mine, nothing like it.

5721. How far can you drive at the lower part of the mine?—We had it between thirty and forty fathoms. I found the air getting bad, and I put in an air machine; I fixed an air machine to the engine-shaft and had a waterfall; then I had another, and had three boys to blow the machine; and as soon as the men had blasted, the air was driven out.

5722. (*Mr. Holland.*) Were the men able to work at less per fathom, after blowing in the air?—We should not give them quite so much.

5723. Did you set it?—Yes.

5724. What difference was there?—I cannot say exactly. It will make a considerable difference whether men can work seven or eight hours, or are obliged to stop two or three.

5725. (*Mr. Austin Bruce.*) Would the difference cover the difference of the cost of the ventilation which you supplied?—More.

5726. (*Mr. Davey.*) I think you prepared these machines cefore there was an actual necessity for them; you saw it coming?—I saw that the air was getting bad. It was not that the air was so very bad, but it was the smoke, and in order to drive out that smoke for the men to make the most of their time, I put in an air machine.

5727. (*Mr. Austin Bruce.*) Do you think it always wise to put in an air machine, when it is wanted?—Yes; when it is wanted.

5728. I mean not only as regards the health of the miners, which of course you feel it your duty to look after, but as regards the pockets of the adventurers?—I am speaking of the advantage to the adventurers; of course it is better for the miners to have the smoke blown out.

5729. Have you ever worked as a miner?—Yes.

5730. Where?—In the western part of the county, in St. Just, and in this neighbourhood. I was 100 fathoms deep, at 11½ years of age, and I have been at it ever since.

5731. How is the ventilation at St. Just?—Balleswidden was the principal mine which I worked in, and there was no deficiency of air there.

5732. Have you ever worked in a bad end?—Yes, I have worked in close ends in three or four places. I worked in a closeish end at Tavistock, the nearest

mine to Tavistock, a little further on than Crelake; it was Crowndale. The air was bad there. I suppose we were off 30 or 40 fathoms.

5733. Did you complain to the captain of being short of air?—No; it was what we termed a closeish end, but not as some people describe it to be, a very bad air end.

5734. How long did you work in it?—About four months.

5735. How were you at the end of the four months?—Just the same.

5736. Did you suffer?—No; I do not know that it had any effect upon my health.

5737. Has your health ever been bad?—No, not from working under ground.

5738. How long were you working under ground?—From 11½ years of age till I was twenty-one.

5739. I suppose a large portion was scarcely hard work?—Yes, it was hard work.

5740. What work had you to do when you first went underground?—When I first went underground, I went to work with tributers at a share. I think I had a third part of a man then.

5741. What work did they make you do?—I was chiefly had to attend them with things and to break up their tamping and fill the quills. They used then to blast the holes, not with safety fuses, but with quills, and I had to get the powder and fill the quills, and all that sort of work.

5742. What was the next work which you did?—Then I went to wheel the stuff back from the tributers.

5743. How old were you when you began that work?—I suppose between twelve and thirteen.

5744. How long did you stop at it?—Until I was about fourteen.

5745. Then what did you do?—I then went to work in the end with men.

5746. What work did you do there?—Driving on the level on tut-work. I went on tut-work three or four years, I think, and after that I went to tribute.

5747. What work did you do? Did you only hold the borer, or did you strike?—I did both; not both at one time, but I changed over.

5748. Is the state of your men's health here good?—Yes, I think very well.

5749. Do you see any difference in different mines, in the state of health?—Yes; you will find that some men, when they get up to about forty, and from that to fifty, appear to feel the effects of working under ground. Whether it is the effect of working under ground, or whether it is brought on by any other complaint, I do not know.

5750. Have you any men here above forty?—Yes, several.

5751. What is the age of the eldest man working under ground?—I cannot say; the oldest must be more than fifty, I should say.

5752. Is he pretty strong and hearty?—Yes; it is a man of the name of Trevedish; he has his three sons working with him, he must be passing fifty, I should think.

5753. Have you now many cases of consumption?—I do not know that it has come under my particular notice, that it was brought on from working under ground in poor air, or any thing of that sort.

5754. Have you not known that formerly, when you were in the west?—I have known men in consumption, but what it has been brought on by I do not profess to understand.

5755. Do you consider, on the whole, mining to be a healthy employment?—I do not consider it as healthy as working on the surface, by a great deal.

5756. What, do you suppose, is the cause of its being less healthy?—Owing to the impurity of the air, I should think.

5757. Would you attribute a part of it to climbing?—Perhaps so.

5758. Climbing up from deep levels?—Yes, I should think so.

5759. Did you yourself feel the effects of climbing from deep levels, after a hard day's work?—It would naturally make one a little tired, when one gets up; but if they go slow, I do not know that it is much worse than their working.

5760. When you were young, did you go slow?—No; I believe that I was wild enough; they used to tell me so.

5761. But you were never any the worse yourself?—No, I do not know that I was.

5762. Was your father a miner?—Yes.

5763. What age did he live to?—He is living now; he is nearly 70.

5764. Did he work long as a miner?—Yes.

5765. Did he become a captain like you?—Yes; I will not say exactly his age, but I think he is very nearly 70. Perhaps you have seen him; he is at Craddock Moor.

5766. (*Mr. Kendall.*) When you worked in those places, in bad air to which you have referred, would it, according to your opinion now, have been more economical if the agent had employed some artificial means to supply pure air?—Yes, I think so. If they had continued that end, they would have been forced to do so, I think; but it was stopped.

5767. Were not some artificial means due to the men before you stopped?—I do not know. It was not what you would term a very bad air, but yet it was getting quite bad enough to have an air machine put in.

5768. And it would have been necessary, if you had proceeded with it?—Yes; and for aught I know the agent meant to have an air-machine put in.

5769. Generally speaking, do agents as a matter of economy use artificial means when they find that the air is bad?—I should think so. They ought to do so for the good of the adventurers as well as for the health of the men.

5770. You have seen a good deal of mines in one place and another, did you ever know an agent refuse to use artificial means after an application was made to him, and he was satisfied that there was bad air?—I do not know that I can state a case.

5771. In your experience, do you know any cases of gross neglect, where the agents, for the sake of the men and for the sake of the adventurers, ought to have forced in air by artificial means, but did not do so?—No; I do not.

5772. (*Mr. Holland.*) Do you not know many cases where the men think that there should be fresh air and the agents do not?—That may be the case.

5773. Very frequently?—Not very frequently.

5774. (*Mr. Austin Bruce.*) Your father was a captain early in life, I dare say?—Yes, when he was about 23 or 24.

5775. Long before you were born, then?—No, not very long before I was born.

5776. What is your age?—Passing 30.

5777. And your father is 70?—He is between 60 and 70. It was not very long before I was born, perhaps he was about 24 or 25.

5778. He was a captain, and had been long a captain before you began to work?—Yes.

5779. What sort of education did you get?—I was at school until I was eleven years and a half old.

5780. Did you go to school afterwards?—No.

5781. Did you do any sort of head-work afterwards besides that immediately connected with your mine?—I do not exactly understand what you mean.

5782. Did you carry on your education at all?—Yes.

5783. (*Mr. Holland.*) Did you go to an evening school?—I think I was at an evening school a little while; however, not long.

5784. (*Mr. Austin Bruce.*) Have you any children?—No.

5785. Is it usual for the captains of mines to put their sons to school now, generally speaking?—Yes, generally.

5786. Until what age?—That rather depends upon their pocket.

5787. From your observation, at what age do they

generally put them to work?—It all depends upon the position of the mine agent; some will keep their children at school until they are perhaps 16 or 17, and some even older, and others are necessitated to put them to work as soon as they are able to work.

5788. If a mine agent keeps his son at school till he is 16 or 17, does he then put him to work?—Yes.

5789. As a tut-worker or a tributer?—He would put him down first of all to do what is termed a boy's work; perhaps to clear out some levels or something of that sort, and then he would go into work with other men at tributer or tut-work.

5790. Until he shows himself fit, if he ever does show himself fit, to be an agent?—I do not know as to that; getting to be an agent or not all depends upon circumstances.

5791. Does it mostly happen that the sons of captains become captains?—I do not know.

5792. Have you any men working as miners in your mine, who are the sons of captains?—No, not now. I had one about a month or two ago. I do not think that we have any one here now.

5793. (*Mr. Holland.*) You stated that the air was bad, but not very bad, in which you had worked?—Yes.

5794. Do you mean that a candle would burn in it?—Yes.

5795. You call it bad, then, before the candle gets dim?—I call it very bad before it will put out a candle.

5796. But before it gets dim; before you have to slope it, in order to make it burn?—Yes, it is bad then.

5797. Very bad?—Yes.

5798. You also said that when the wind blew from the west, you had one current in the mine, and that when the wind blew from the east the current was the opposite way?—Yes; but that is only above the 40 fathoms; that has nothing to do with the state of things down in the actual working of the mine.

5799. Which is the best for the mine?—I do not know; there is very little difference.

5800. Would it not be the best if it always went the same way?—No, I think not; I do not know that it would make any difference whatever. It is not as if it was a current which would pass down to the working part of the mine. I was asked about the up-cast and the down-cast in the shaft; the up-cast and down-cast below are always the same.

5801. (*Mr. Austin Bruce.*) Is there an advantage in their being always the same?—Yes; I should think there was.

5802. (*Mr. Holland.*) Would it not be easy always to make the wind go in the same direction in the mine, though it may be different on the surface. For instance, by a wind sail to turn towards the wind, and always bring the current down the same shaft. Have you seen that done?—I have seen it put up many times, but I have never seen it done in order to keep the current always in one direction.

5803. Is it not commonly done in Cornwall?—I never saw it.

5804. Nor anywhere else out of Cornwall?—No; I never saw it either in Cornwall or out of Cornwall.

5805. Have you not heard that it is a very common thing to be done in the northern mines?—No. What do you mean by the northern mines, the coal-mines?

5806. Yes, some of the smaller coal mines?—I do not know anything at all about them; in fact I do not know that I ever heard of its being done. I have known many instances where sails have been put up to convey the air down the shaft, but not to keep the air a particular way in that shaft.

5807. Have you not seen a malt-house ventilated in that way?—No.

5808. Supposing that such a plan were found to to answer well in Northumberland, do you not think that it would answer well in Cornwall?—Yes, I should think so. I do not see why it should not.

5809. (*Mr. Kendall.*) Which do you think would make the best practical mine agents, those who go underground very early, say at 10 or 11, or those who are kept longer at school and go underground at, say 16 or 18?—I do not know. I should almost take just between the two ages.

5810. You would not have them put underground too early or too late?—No.

5811. You think that if they went too late they would not undergo the necessary work?—I would not give much for them if they are only put down when they get up to 17 or 18. I would rather have them underground at 14 or 15.

5812. You would take the mean? You would keep them rather longer at school?—Yes.

5813. And let them go underground at about 13 or 14?—About 14; and then up to 14 I think that a youth ought to learn just as much as would be required of him in his station in life. Then, of course, he ought to improve a little on that afterwards.

5814. (*Mr. Davey.*) You think that a captain's son, at 17 or 18, would not condescend to the drudgery which is necessary to make him a working miner?—I do not know; perhaps he would. For my part, I should say 14, or at least not at all above 15. Let him take the work by the handle; that would be the best way for him to thoroughly understand mining.

5815. (*Mr. Holland.*) A man would only work about eight hours a day, would he?—About eight hours a day.

5816. Would he not have a good deal of leisure in the rest of the day for study, if he chose?—Yes.

5817. He might read or cypher two or three hours a day easily?—Yes.

5818. Do they generally do so?—No; I am sorry to say that that is generally neglected.

5319. What do they do with all their leisure time?—In some places they have little gardens which they cultivate.

5820. Not all that time?—No; it will not require all the time. At other times I suppose they sit down, and it is too frequently the case that they idle about their time. However, the agents have no power over the men; as soon as they leave the mine they are free.

5821. (*Chairman.*) What do they learn under 18 that a man could not learn after he was 18, with regard to the business of a mine?—Generally speaking, when they are put underground at 18, they are men, and they want to go in and take men's places at once; but if they are put underground at about 14, they will take the work at the beginning and go right through with it. I do not mean to say that for a moment, that a man will be disqualified because he does not go undergrounnd before he is 18; I do not mean to say that such a man might not learn and become a good practical man; but I think the chances are more in favour of a boy who goes underground at 14 or 15.

5822. But a well educated man at 18, with an observing mind, might become a very good captain?—Yes; and I have no doubt there are many such.

5823. Without having gone through what you call the drudgery of boys' work?—Yes; but I think it is necessary for a man to know a little in order to set the work to others.

5824. But still he could learn that, I suppose?—Yes.

5825. With respect to the machines, have you a boy for each eight hours?—Yes; when we have the air machines.

5826. Does that machine require to be driven quickly?—No, not very fast.

5827. Does it require him to be kept constantly at work?—No.

5828. How often?—Perhaps in spells of about a quarter of an hour at a time, and then he might strike for a quarter of an hour. When they blast he would be wanted to work it round pretty fast, perhaps for half an hour.

5829. They call to him at that time?—Yes; they come to that place. They always place the machine where there is good air.

St. Austell.

Capt. T. Taylor.

24 April 1862.

5830. The machine is to blow the powder smoke out?—To blow in the good air and to force out the smoke and the foul air created by the men being there and by the blasting.

5831. But the chief object is to get rid of the smoke?—In getting rid of the smoke you get rid of the foul air.

5832. Do you suppose that all mines have these machines in them?—No; in some places they are not required. In fact, we have no machine to work now; we do not require it.

5833. But should there always be one in the mine ready?—They are very simple to be constructed.

5834. Do you always have one ready in the mine when it is wanted?—No; not at all times. The one which we took out very likely would not go in again, because it is worn out, and then we should have another.

5835. Who makes them?—They are made on the mine.

5836. How long are you in making them?—The carpenters would make a machine in three or four days; that is to say, the carpenters and blacksmiths. They are chiefly fan machines; but in many places they are better than that, where they work their machines with the engine and draw a regular storm of air.

5837. That you consider much better?—Yes; there is greater power.

5838. Why is that plan not generally adopted?—It is not at all times that you can get it so that it will suit, and it is bad perhaps to connect it with the engine shaft.

5839. It is more expensive?—Yes.

5840. Is the air taken down in pipes?—No.

5841. It merely goes down the main shaft?—Yes; it is forced in from there.

5842. But is it ever forced in through pipes?—Yes; it is not taken down from the surface, but from the engine shaft in through the pipes. Generally speaking, in the engine shaft they get the air very good.

5843. (*Mr. Holland.*) That is the down-cast shaft of course?—Yes.

The witness withdrew.

The Commissioners took the following evidence at Kelly Bray mines:—

A Miner (No. 1) examined.

A Miner (No. 1).

5844. (*Chairman.*) How long have you been working as a miner?—I went to work underground when I was 10.

5845. How old are you now?—In my 59th year.

5846. At what work have you worked principally, tribute or tut-work?—Tut-work chiefly.

5847. In what part of Cornwall?—About from St. Austell; I worked for a great many years about.

5848. In what mines there did you work?—The East Crinnis, and Old Crinnis, and another mine; that was the first of my commencement.

5849. Did you ever suffer from working at tut-work?—No; nothing of any consequence.

5850. Are you working at tut-work now?—Yes.

5851. Did you ever work in any poor ends?—Yes, I have worked in poor air.

5852. Did you feel it?—I felt it then for a time; but it passed away again.

5853. How did you feel it?—I felt it in my stomach and in my head.

5854. What did you do when you felt it?—I was laid up one time for about three weeks. I believe that was the longest time that ever I was laid up since I have been underground.

5855. Did you go back to the same work?—Yes; I went to the same place again.

5856. Where was that?—That was at Landiscot.

5857. (*Mr. Kendall.*) Now called Fowey Consols?—Yes.

5858. (*Chairman.*) Was the air the same when you went back?—No; the place was holed; ventilated.

5859. You were driving an end then?—Yes.

5860. Do you know how far that end was when you were taken ill, from the nearest winze?—We were in, I suppose, somewhere about 70 fathoms from the shaft.

5861. Between the shaft and that there were winzes, were there not?—No; there was no winze at all there.

5862. So that you drove 70 fathoms without any air but from the shaft?—Yes.

5863. Was there any cross-cut?—No.

5864. Were you driving a cross-cut?—No; we were driving upon the course of the lode.

5865. Just clearing it away for the tribute-men?—Yes.

5866. About how long ago is that?—I suppose about 27 or 28 years ago; over that, it must be 30 years ago.

5867. Was anything done to give you air while you were working?—No; we holed. There was another pair that was driving from another part of the mine.

5868. But till the other pair met you you did not get air?—No.

5869. You went back again to the same work?—Yes.

5870. And at that time the others had finished the hole?—Yes.

5871. Where did you work after that; do you remember?—I worked there for a short time, and then I went back to East Crinnis.

5872. Did you work in any poor air there?—No.

5873. Did you work as a tut-work man there?—Yes.

5874. Do you remember any other mine where you worked in poor air?—No; I do not know that I do particularly.

5875. If there was poor air now in any mine at work should you give it up?—Yes; I should not think of working in poor air now. I am too far gone in years.

5876. But would a young man go on working although it was poor air?—Yes; it would depend upon the means for getting money, or anything of that sort. Sometimes a man will work a little more than he will at other times.

5877. Are they paid more where it is poor air?—Yes, sometimes.

5878. For the sake of earning a little more they would work in poor air?—Yes, many men would.

5879. Then they stand a chance of suffering from it?—Yes.

5880. Have you any sons?—Yes; I have two sons.

5881. Are they working?—I have one in America, and one is in the north part of England.

5882. Were they miners?—Yes.

5883. Had they suffered at all?—No; not from poor air.

5884. (*Mr. Kendall.*) You are now 59; do you take a man's place?—Yes.

5885. Do you consider yourself in full strength now, an able-bodied man?—Yes.

5886. As I understand you, you once drove 70 fathoms without any fan or any artificial means at all?—Yes.

5887. How long did you work there before you felt ill?—I was there, I think, about ten months in that level.

5888. During the ten months, taking an average with reference to smoke in the end, how long did the smoke lie there before you could go back again to work?—Sometimes longer than others.

5889. Take an average?—I can hardly say. We generally cast a shot of two holes together; then we stop a very little bit, and if it was not exactly clear

when we went in, we should take our waistcoat or something and brush about to clear the smoke to come to work.

5890. Taking an average, taking one time with the other, how long was it before you went in? — About half an hour.

5891. And then sometimes if you found that the smoke did not go fast enough you took your coat or waistcoat and blew it out?—Yes.

5892. When you were there did you complain to the captain at all about bad air?—Yes, very often; but in some places there are hardly conveniences to throw in air.

5893. Before you got ill did you talk to the captains about it?—Yes, at different times.

5894. What did they say?—They said that they knew that the place was bad, but that it could not be ventilated for some time, and so on.

5895. That you must push on?—Yes; and do the best we could.

5896. You have seen a great many men. In your experience do many of those whom you have seen, in your opinion, suffer from bad air?—Yes.

5897. In Landiscot do they suffer much from bad air?—Yes, I suppose so. I have not been there for a great many years.

5898. From what you see generally in mining are agents more careful in sending in air by machines than they used to be?—Yes; I cannot find any fault with the agents.

5899. Are they improved now from what they used to be?—Yes; I believe they are. I believe that almost every agent is willing for people to have as good a place as he can possibly make for them.

5900. Since you can recollect is there an improved mode of ventilation?—Yes, I think there is.

5901. Do you find a good deal of fatigue from climbing now?—No, not in our mine. Our mine is a shallow mine.

5902. What is the deepest mine you ever worked in?—Landiscot was the deepest.

5903. What depth was that?—I do not know the depth there now.

5904. When you were there what was the deepest level in which you worked?—I worked at the 90 fathoms there.

5905. 90 fathoms under the adit?—Yes.

5906. What is the adit?—About 40 fathoms, I suppose, to one shaft, to Coates's shaft.

5907. Used you to feel it very fatiguing to come up?—Yes.

5908. It was smart work?—Yes.

5909. Used the men at all to wait for the 2 o'clock bell to strike? How did you manage about getting up in time?—I could get away. We used to go by the jobs that we did, in general, shooting so many holes, and that like.

5910. And could you judge pretty nearly the time by the holes themselves?—Yes; by our work, and so on.

5911. How used you to manage if you got up a little too soon?—Sometimes we were not allowed to get up too soon.

5912. How did you manage then; supposing you left work a little too soon, and found that you were too early, where did you stop before you got up; supposing that you ought to be up at two o'clock, and you found just as you got very near the surface that it was only half past one, what should you do?—Go right up.

5913. (*Chairman.*) Have you never been fined for being too soon?—I cannot say that I never was fined, because I have been.

5914. (*Mr. Kendall.*) Was it the habit for the men to wait a little down in the large shaft in order to see that it was two o'clock?—There is a place for people to rest a bit before they get up.

5915. What should you think that the miners suffer most from, from bad air, or from catching cold through coming to the surface hot?—I do not know. There are a great many places where people work in a very hot place, and people might be liable to catch cold, and such a thing as that.

5916. (*Mr. Austin Bruce.*) When you were fined how long were you up before the time?—Some time; it would depend upon time; it might be half an hour, or just like that.

5917. Supposing you were up 10 minutes before your time, would you be fined then?—No.

5918. When you were in that long level which you were speaking of, was a fan put in after you left?—No; they holed. There was another level that was coming from another part of the mine, from another shaft.

5919. Could you see any difficulty in putting a fan, in that case?—I do not know, I am sure.

5920. Why should a fan have been more difficult there than anywhere else?—There are many places where things ought to have been made better than what has been in times that are past, without a doubt.

5921. Are you the oldest man in this mine?—No.

5922. There are others older than yourself working below ground?—Yes, there is another man down to our level, I believe. No, I do not think that he is hardly so old as I am.

5923. Is there any older than you?—No; not in this mine.

5924. Are there many of about the same age?—Yes; about the country there is, no doubt.

5925. But in this mine?—No; I do not know that there are.

5926. Are any of the men who were of the same age as yourself still working as miners?—Yes.

5927. Where are they working as miners?—I do not know; in different parts of the country, men that I have worked with.

5928. Is it a very common thing for a man to be still working under ground as a miner at the age of 59?—No; it is not; not upon the average.

5929. Have you been working lately as a tut-work man?—No; only this month. I have worked upon tribute in this mine for the last 14 months before this month.

5930. (*Chairman.*) Why did you give it up?—I do not know.

5931. (*Mr. Austin Bruce.*) What end is there in this mine furthest from a shaft or a winze?—It is not far. This mine is a good air mine.

5932. (*Chairman.*) How far is the nearest winze? About 12 or 14 fathoms, I suppose, or something of that sort.

The witness withdrew.

A Miner (No. 2)—examined.

5933. (*Chairman.*) Have you been long working in mines?—Yes, about 27 years; from my childhood up.

5934. In this county?—Yes; always here, within a few miles, except six years, when I was in Germany.

5935. How long have you been in this mine?—About two years since I came home from abroad.

5936. What mine did you work in before you went abroad?—Here, about eight years before I left.

5937. Have you worked in any other mines besides this?—Yes, at Holmbush mine. I have worked at different mines about this neighbourhood, all within five or six miles.

5938. Have you worked in any mines where you have had bad air at all?—No; excepting Holmbush. I did not work there long. I worked in one end that was rather bad air, only about five or six months.

5939. How did you know that it was poor air there?—Because it affected my breathing.

5940. Did it affect the candles?—Yes.

5941. If the candles had burnt well, should you still

St. Austell. *A Miner (No. 2).* 24 April 1862.

have thought it poor air?—We found out by the candles that it was poor air, certainly.

5942. That is the way you judge?—Yes; and we could find it to be poor air by breathing it.

5943. Do you feel any difference when it is hot air?—I never worked when the air was hot.

5944. Did you find your breathing affected before you saw the candle fail?—I do not know that I did.

5945. What was the effect upon yourself?—In climbing, when we do climb the ladders in the shaft, we feel our legs ache more than in good air.

5946. Is there any other feeling?—No other feeling more than that. I did not work in it long, only five or six months; that was at the hole at the winze that was coming down on me; this winze was coming down on me.

5947. Were there any means to throw in air to you?—Yes; as soon as this winze was holed.

5948. But not before then?—Not before.

5949. Did you complain about it?—I cannot say; it is so many years ago since I worked in poor air; it must be nearly 15 or 16 years ago.

5950. Would you work in poor air now if you knew it?—No.

5951. You would give it up?—Certainly.

5952. You think that it would injure your health?—Yes; poor air would injure anybody's health; but I do not think that it injures the health so much as is considered.

5953. What then do you consider injures the miner's health?—I am sure I cannot say what it is.

5954. Do men work in poor air still?—I have no doubt that they do in many places, but not in this mine; this is a very good mine.

5955. I suppose you would always prefer going to a mine where the air was good?—Yes.

5956. Are you working on tut-work here?—Yes.

5957. Are any of the men in the same pair with you older than you?—I think two are older than me.

5958. Have they been long here?—I cannot say; they have worked here ever since I have been here, in the last two years, and how long before I cannot say.

5959. (*Mr. Kendall.*) When you were at Holmbush, and there was bad air, how many men were working in a bad end at that time?—I am sure I cannot say whether there was any person except in the end which we were working in. I was never told whether there were more or not.

5960. Surely if there were other bad ends you would hear something from the men about their being bad ends?—I might, but I cannot say. It is 16 or 17 years since I worked there.

5961. And you say that the mine here is a well ventilated mine?—Yes; it is good everywhere. There is not a bad air place in the mine.

5962. (*Mr. Fulke Egerton.*) You said that you thought that the bad air did not do so much harm as was generally supposed?—I fancy so, but I cannot say. I never worked at it long myself.

5963. Do you think that the climbing of the ladders does harm?—I am sure I cannot say. Perhaps it would if they were climbed hard; but if men take their time in climbing I do not think that it injures the miners a great deal.

5964. (*Mr. St. Aubyn.*) What do you think does harm; if it is not the bad air or the ladders, what do you think it is?—I am sure I cannot say what it is.

5965. (*Mr. Fulke Egerton.*) Do you think that men are likely to catch cold on coming out of the mine before they change?—Men working in a very warm place are more liable to catch cold than people working in cold places. Mine is a very cold mine.

5966. You do not yourself come out of the mine very hot?—No.

5967. Not even after climbing the ladders?—Climbing the ladders here does not make a person hot at all. They are slanting, except just 40 fathoms, and the shaft here is very cold.

5968. (*Mr. Kendall.*) You have a nice dry here, have you not?—Yes, we have a very good dry.

5969. And the mine is a dry mine too?—A very dry mine.

5970. (*Mr. Austin Bruce.*) Is the shaft up which you climb up-cast by which the air returns?—The draught plays down one way and up the other. The shaft is divided into two. In fact we have two shafts in our mine.

5971. Is the ladder by which you come up in the up-cast shaft or in the down-cast?—It is in the one that the engine is in; the one in which the lode is working; not the one that we draw our stuff in.

5972. Does the return air come up with you or not?—It comes up where we come up.

5973. Does that add at all to the difficulty of climbing?—Not at all.

5974. Has not the air sometimes a good deal of smoke in it?—No, there is very little smoke in this shaft. The smoke does not come up the shaft where we come up, but up another shaft a little further on, and it goes as deep as the mine. It is the second shaft. The air goes down one way and up the other.

5975. (*Mr. Holland.*) Does not the smoke come up the up-cast shaft?—Very little comes up that shaft. Sometimes when the wind gets round it makes a little difference.

5976. Did you not state that after you had been working in bad air your knees trembled under you?—No, I never said so as to this mine.

5977. Did you not say that after working in poor air, you found your knees trembling under you when you came up the footway?—Yes; that is what I said.

5978. Do you think that they trembled more than usual after working in poor air?—There is greater difficulty in travelling after working in poor air; in climbing.

5979. Did it make you pant more?—Yes; it affected my chest more than usual.

5980. Did it make your heart beat more than usual?—Yes.

5981. Did it make your head throb more than usual?—Yes.

5982. Altogether you found the labour, after working in poor air, more than usual?—Yes.

5983. (*Mr. Holland.*) Do you know that miners are a sickly race?—Some of them are, and you will find in every race that there are sickly men; but I do not know whether there is so much of that in other labour as there is with the miners.

The witness withdrew.

Captain Silas James examined.

Capt. S. James.

5984. (*Chairman.*) How long have you worked as a miner?—I am now 57 years of age, and I went to work underground when I was about 11 years of age.

5985. How long did you work underground before you became a captain?—I became an agent when I was about 40 years of age,

5986. You have been 17 years an agent?—Yes.

5987. Were you an agent anywhere else before coming here?—Yes.

5988. In what mine?—A mine in the parish of Beer Ferris in Devon. The mine was called Green Valley.

5989. What description of mine was it?—A lead mine.

5990. What depth was the lowest level?—Fifty-seven fathoms deep, I think.

5991. What is the deepest mine that you have ever worked in?—I think this mine here.

5992. What is the depth of this mine?—The deepest point is 135 fathoms.

5993. What are you working at now ?—The deepest level that we are working at now is the 85 fathoms.

5994. How many shafts are there in this mine ?—Four.

5995. Which is the footway ?—There is one footway for the Western mine, and up the other engine shaft is the footway for the Eastern mine.

5996. There is no protection between the footway and the pumping shaft ?—No.

5997. Have you never had any accident there ?—No.

5998. Do you not think that there ought to be some protection between the pumping shaft and the footway ?—If there was, nothing would stop an accident ; if the beam was to break there must be a pretty protection to stop it. We put rails on the ladders to keep everyone safe.

5999. For the protection of the men should there not be some protection between the ladders and the shaft ?—We have rails at the bottom and top of every ladder.

6000. But none at the side ?—No.

6001. How many men have you working underground ?—We have somewhere about 50 underground now. We have not so many as we had a little back.

6002. Have you ever had occasion to use any artificial means of ventilation here ?—At a particular time we have when we have had a long level, and have been making a communication to a level above by winzes and like that ; but then we keep a fan machine, and that does not occupy more than a month or two.

6003. What is the longest level that you have ever driven here ?—One level at the Eastern mine now, I think, is about 70 fathoms east of the shaft, and that is done by a fall of water from the adit. We have communicated from that by a winze, and that is first-rate air.

6004. (*Mr. Kendall.*) As I understand, you are now 57 ?—I am in my 57th year.

6005. And you worked 29 years underground as a common miner ?—Yes.

6006. Did you work mostly upon tribute or upon tut-work ?—The greatest part of my work in the first commencement was in engine shafts. Then I worked a great deal upon tribute. I worked in the Great Huel Towan as a sumpt man ; that was the first place I ever worked in a shaft ; I was there for nine years.

6007. How deep did you go in the sumpt shaft ?—The deepest point in that mine was 132 fathoms.

6008. How is your health now ?—First-rate; capital. I would not mind climbing the ladders ; I go underground now three days a week.

6009. Can you go up and down the ladders as well as ever you could ?—Of course not so well as when I was 20 years of age ; but better than scores of men. I can climb now from the bottom of this mine to the top without stopping, if I like.

6010. (*Chairman.*) And you do not feel it ?—Of course I feel that I breathe shorter ; but nothing to be alarmed at.

6011. (*Mr. Kendall.*) You are not, of course, as strong now as you were when you were a young man ; but do you feel it very fatiguing to come up from the bottom of your mine now ?—No ; not at all.

6012. You feel able to do it ?—Yes.

6013. And well able to do it ?—Yes.

6014. When you go under ground, I suppose you visit almost every pitch ?—Yes, generally.

6015. And you generally go to the bottom of the mine ?—Yes ; particularly to that mine up there. At this mine we are not working at the bottow now ; but it is not long since I have inspected and have gone through both mines in one day, from the bottom level to the top.

6016. What is your bottom level now?—One hundred and thirty-five fathoms ; but we are not working there.

6017. How deep are your deepest workings now?—Eighty-five fathoms.

6018. And that is how far under the adit ?—We have no adit at all here.

6019. When you go down three times a week, you generally go to the very bottom of that mine, and visit all the pitches ?—I went six days last week ; every day of the week.

6020. You say that you go probably three times a week, but sometimes six times a week ?—I went six times last week.

6021. Though you are 57, do you feel able to do that work now without inconvenience ?—Yes, certainly ; and many times I go down in this mine, as I have no agent here but myself, and visit all the pitches in this mine ; and go up and down the 70 fathoms again all in one day.

6022. After having done this mine, which is 85 fathoms deep, you view the 70 fathoms mine ?—Yes ; and view every place, and come up afterwards.

6023. And set to the men ?—Yes.

6024. After that, I suppose you feel a little tired ?—Not particularly.

6025. (*Mr. Davey.*) How long would it take you to climb 70 fathoms in a quiet way ?—About 20 minutes.

6026. (*Mr. Kendall.*) Was your father a miner?—Yes.

6027. How old was he when he died ?—Passing 81.

6028. How long was he an agent of a mine ?—About 25 years.

6029. Up to what age was he an agent of a mine ?—Till he was 72.

6030. How late did he go underground ?—Up to that time.

6031. Of what mine was he agent ?—The last mines he was in were the Tamar Mines.

6032. How deep were they ?—To the 212 fathoms, I think.

6033. Did he ever go as deep as that ?—Yes.

6034. That is a rare case, is it not ?—Yes.

6035. (*Chairman.*) Have you been employed as agent to inspect other mines ?—Yes, several times.

6036. In what part of the country ?—The Tavistock United Mines, the Devon and Courtenay, the Tavey Consols, Huel Arthur, Huel Edward, Holmbush Mine, Redmoor Mine, and Kitthill Mine.

6037. Are any of those mines deep mines ?—Not particularly; Holmbush is the deepest.

6038. Are those established mines ?—Yes.

6039. (*Mr. Kendall.*) Turning over a good deal of ore ?—Yes.

6040. (*Chairman.*) In those mines, have you found any poor ends ?—No ; not particularly.

6041. But there have been some poor ends ?—Certainly ; there is occasionally dead air in mines. but it is always the agents' wish to try their utmost to get ventilation as quickly as possible.

6042. But delay occurs in getting ventilation ?—Yes ; and it will be so as long as a mine is a mine.

6043. (*Mr. Kendall.*) You hold this mine to be well ventilated ?—Yes.

6044. Are the other mines as well ventilated as this ?—Yes ; generally.

6045. (*Chairman.*) But there are some which are not ?—Yes.

6046. (*Mr. Holland.*) How do you judge that the ventilation is bad ?—Because a candle will not burn.

6047. Is it not bad for you a long time before it gets bad for the candle ?—No ; the candle will find it out first.

6048. (*Chairman.*) In any of these mines, did you see that the candle would not burn ?—I have been down in the deep levels at 170 fathoms in Holmbush ; of course it is warm below, but the air is middling.

6049. How long can a man work in those levels ?—For eight hours.

6050. (*Mr. Davey.*) How long is it since you inspected Holmbush ?—About two years ago.

6051. (*Chairman.*) What heat was there then ?—I do not know exactly. I inspected Holmbush twice.

6052. (*Mr. Davey.*) Did you find the air impure there ?—No ; I cannot call it impure at all.

St. Austell.
Capt. S. James.
24 April 1862.

6053. (*Chairman.*) But it was hot ?—Yes.

6054. (*Mr. Davey.*) Do you not know that you may have heat, and at the same time good ventilation? —Yes ; you may have a current of air passing round a good many times.

6055. (*Mr. Holland.*) You can have heat with air passing round and round ?—Yes.

6056. But you do not call that good air do you ?—Yes.

6057. When the air gets hot, is it not a proof that it is the same air coming round again ?—No ; as it goes down into the deep mines, of course the air is warm, and as it traverses the deep mines it is warm.

6058. (*Mr. Davey.*) But the heat of the earth will not destroy much of the quality of the air ?—No.

6059. (*Mr. Holland.*) When there is a flow of air through the mine, do you not find it cooler ?—The greater the circulation, the cooler it is of course.

The Commissioners took the following evidence at Holmbush mine :—

A Miner (No. 1.)
A Miner (No. 2.) } Examined.

A Miner (No. 1) and A Miner (No. 2).

6060. (*Chairman to Miner No.* 1.) How long have you been working here ?—Between four and five years.

6061. Where have you worked before ?—I have worked at several mines before I worked here.

6062. Do you work at tut-work ?—Yes ; I and this man are comrades ; we work together.

6063. Are there any bad ends here ?—No, not that I am aware of.

6064. How deep do you work ?—Ours is the bottom end ; there is a hole close behind me.

6065 So that the smoke gets away quickly?—No.

6066. What other mines have you ever worked in ? —I have worked in Huel Maria and in another mine.

6067. Did you ever work in any mines in poor air? —No ; I never worked in poor air in my life.

6068. Do you inquire before you go to a mine what the air is ?—Yes ; I generally inquire of the men what sort of a place it is to work in, so as to know before I go to work.

6069. I suppose you would not go to work if you knew that there was poor air ?—No, I should not wish to work in poor air.

6070. Do you know that any of your comrades have ever worked in poor air and suffered from it?—I do not know that I have heard them say anything about it. It is the poor air that injures us.

6071. (*To Miner No.* 2.) Have you worked in poor air ?—Yes, I have before now.

6072. How did it affect you ?—It made my legs ache and my stomach bad.

6073. How did you first find it out ?—My legs ached very much in climbing up ; my candle would not burn very well unless it was put on the side.

6474. Did you go on working ?—Yes, for a good while. The mine is drowned now ; it is the Kerris mine, in Devonshire ; it is the South Tamar Consols.

6575. How long did you work there ?—Four or five years.

6076. How long did you ever work in poor air ?— Two or three months before I could see the chance of getting a better place.

6077. What level was it in the mine that you were working in ?—Only to the 70 fathoms.

6078. Were you driving an end ?—Yes.

6079. Were there any means to improve the air ;— No, not there, for the time.

6080. Did you apply to have any means ? Did you ask the agent for any means ?—No.

6081. But you went on working ?—Yes.

6082. Did none of the others complain ?—No, not to the agent, because it was too far off to get any other air than what we had.

6083. You knew that they could not get air there? —Yes.

6084. Have you never seen any machine for supplying air ?—I have before now, but not there.

6085. They had not any there ?—They had them there in some parts of the mine.

6086. Why did not they give it you ?— I am sure I do not know.

6087. Did the agents know that the air was poor air ?—Not so well as we did, because they were not there so often as we were.

6088. But I suppose they did know that there was poor air ?—Yes.

6089. Did you feel it after you left ?—No, no much.

6090. Did you never feel your breath affected ?— Yes ; I have felt my stomach ache.

6091. But not since you left ?—No.

6092. I suppose you would not go again into poor air if you knew it ?—I should not like it if I could help it.

6093. Did they pay you more for working in poor air ?—We had tolerably good wages there.

6094. (*Mr. Davey.*) What object had they in driving this level ?—They were driving for lead.

6095. Were they driving on the lode or on the cross-cut ?—They were driving on the lode. There was a lode, but they were not working it for a time.

6096. Were no winzes sunk from the level above ? —Not for a long way back from where this end was.

6097. How far back ?— Perhaps 50 or 60 fathoms.

6098. You say that there were no means of throwing in air ?—No ; because there was no end in from the shaft, so far as that was.

6099. But why could they not throw in air from the shaft, either by a soller or by a fan ?—It was too far back ; it was 70 fathoms back from a winze, and the shaft, I suppose, was 100 fathoms from that.

6100. What air was it where the winze was ?— It was better.

6101. Could not they apply a machine there ?— They never did. The end where I worked was stopped for want of air ; the air was so bad there that we could not fire a hole or keep a candle burning.

6002. Have you worked in bad air anywhere else ? —No.

610. You are not obliged to work in bad air ?— No ; but when a man wants to get a living he wants to work somewhere or other.

6103. Are you obliged to do it because you cannot get work elsewhere ?—Sometimes a man might be so, and sometimes a man could get a pound a month more there than elsewhere.

6104. Might it not be also that you worked in bad air for the purpose of getting more money ?—Yes.

6105. Could you have worked in the mine at any other place. On the setting day could you have taken another bargain ?—Yes.

6106. Where it was better ventilated ?—Yes.

6107. But you preferred this for the purpose of getting a pound a month more ?—Yes, sometimes.

6108. (*To Miner No.* 1.) You said that you never worked in bad air ?—No.

6109. But you always found that you could get places which were well ventilated, to work in, instead of working in bad air ?—Yes.

6110. (*To Miner No.* 2.) Do you think that there were any other places in the mine at South Tamar which were badly ventilated ?—There was no place which was so bad as in that end ; that end was driven the furthest from the draught of any that were there.

6112. You are now working here at Holmbush ? —Yes.

6113. What kind of ventilation is there here ?— Tolerably well where I am working ; I do not know much about this mine ; I have only been here about two months.

6114. In what level do you work ?—The 170 fathoms.

6115. Upon tut-work or tribute ?—(*Miner No.* 1.) Tut-work.

6116. How far is your present end from a winze or a shaft ?—Only about 10 fathoms from a winze.

6117. And therefore, you have of course very good air ?—Yes. (*Miner No.* 2.) A draught.

6118. How far do they generally drive a level before they get to a winze ?—(*Miner No.* 1.) It is warm, and they get the air quicker.

6119. Before the air gets dead, do they push with the winze so as to get down in time ?—Yes ; I have known winzes down before the end has been got in.

6120. (*Chairman.*) Is the air here warm ?—It is warm, but not so that men could not work ; I have been working there four years, and it does not hurt me a bit.

6121. You work naked, I suppose ?—Yes, sometimes ; and sometimes we have a thin thing on. Some work naked and some do not.

6122. (*Mr Kendall.*) What you mean by working naked is having your trowsers on, and only being naked down to your waist ?—Yes.

6123. (*Chairman to Miner No.* 2.) How old are you ?—About 28.

6124. You have never suffered from what you have been working in ?—No.

6125. (*To Miner No.* 1.) Do you climb the 170 fathoms ?—Yes.

6126. Do you feel anything from climbing to affect you ?—No.

6127. You do not mind it ?—(*Miner No.* 2.) We should stop to rest. St. Austell

6128. Does climbing the ladders affect your breathing ?—No. *A Miner (No. 1) and A Miner (No. 2).*

6129. Do you come up quickly ?—We take our time coming up.

6130. (*Mr. Davey.*) How long do you think that it takes you to come up quietly from the 170 fathoms to grass ?—(*Miner No.* 1.) About half an hour ; we can come up in less. (*Miner No.* 2.) It would take half an hour to come up steadily. 24 April 1862.

6131. (*Chairman to Miner No.* 1.) Are you fined if you come up to grass before the bell rings ?—We cannot tell what the time is exactly ; we are oftener behind than before.

6132. (*Mr Davey.*) Do the men accumulate near the surface just before the bell rings ?—No.

6133. They are not afraid of coming up before their time ?—No ; they would sooner come up than stop, if they should be before time ; a man cannot tell the time exactly.

6134. Supposing the men came up half an hour before time, would they be spaled ?—I do not know that I ever knew a man spaled for coming up so nigh as that.

6135. You are sometimes after the time and sometimes before the time ?—Yes. (*Miner No.* 2.) Then they carry one against the other.

The witnesses withdrew.

Mr. John Borlase examined.

6136. (*Chairman.*) How long have you been at this mine as agent ?—About 15 months. *Mr. J. Borlase.*

6137. Were you captain at another mine before that ?—Yes ; I was at Huel Prosper in Breage ; I was at the Great Brigan Mine by Redruth about six weeks, and then I was removed from there here.

6138. I suppose you have worked underground ?—Yes.

6139. For how long ?—I have been at the mining from my childhood up.

6140. What age are you ?—45.

6141. Have you ever inspected any other mines ?—No, I never did much of that ; but I have been engaged in several different other mines, mines in the western part of Cornwall, in the neighbourhood of St. Just and Gwinear.

6142. What is the deepest mine that you have ever been in ?—This is the deepest.

6143. What is the depth of this ?—It is more than 200 fathoms from the surface ; the adit level is from 10 to 12 fathoms.

6144. Are you working the lower portion ?—Yes.

6145. About how many men have you underground ?—I think underground and at the surface we have altogether somewhere about 220 or 230 ; we have not got a great many at the surface ; we have a good many children, and it would take some time to go into the calculation.

6146. Are most of the men tributers ?—The greatest portion of them ; but there are several tut-work men driving the 160 fathoms end west, and the 165 fathoms end east, the 40 fathoms east and west, the 20 fathoms east, and the 10 fathoms east.

6147. How far are they driving from any winze or lode ; what is the greatest distance ?—Our end is going on about six fathoms west of a winze ; we put another winze there.

6148. Do you put a winze before you drive ?—Yes, before the end gets in. We have good ventilation here ; there is not a large mine in the county better ventilated than this is.

6149. Is there any particular shaft which is upcast or down-cast, or do they vary ?—We have a diagonal one ; but we have two shafts. We sank the down right, and the diagonal close on the course of the lode, and we had cross-cuts from one to the other, so that there was a communication.

6150. Is there one shaft up-cast and the other down-cast ?—Yes.

6151. Is it always the same ?—It varies sometimes.

6152. Can you account for that ?—I do not know that I can exactly. The shaft is divided from the whim shaft to the engine shaft ; you sometimes find that the draught goes down the whim shaft and up the engine shaft, and sometimes, if the wind should happen to tack a bit, it goes quite the reverse.

6153. (*Mr. Davey.*) You say that the mine is generally well ventilated ?—Yes.

6154. Have you any end at all where the air is rather bad ?—No ; we have not got such an end in the mine.

6155. Then you usually prepare for the air being impregnated by sinking a winze before the end ?—Yes.

6156. Can you always do that by water ?—It is rather expensive, but we go as far as we can with water, and we have communication as soon as possible.

6157. What is your usual distance from one winze to another ?—Sometimes we get winzes ten fathoms, and sometimes fifteen or twenty fathoms, according to circumstances.

6158. If it is rich in metal, it goes a little closer ?—Yes ; circumstances alter cases.

6159. Do you find any difference in the air, when the lode is rich and when it is poor ?—We find it a great deal warmer when the lode is rich, but I believe that the air is as pure.

6160. You say that you have been an agent for some other mines in the West ?—Yes.

6161. How are they generally ventilated ?—The mines that ever I was in are ventilated very well. In the last mine where I was we sank winzes regularly at every fifteen fathoms.

6162. Do you find the men sometimes come to complain of bad air, without cause for it ?—Sometimes they will complain in consequence of a little stuff in the level. It is not at all times that you get the levels clear, and then you find the air a little light.

6163. Supposing a man came to you to complain of the air being imperfect, what would you do ?—I should get it clear as quickly as possible.

6164. You would take notice of it ?—Quite so. Being accustomed to it, and knowing what it is to be

St. Austell. — Mr. J. Borlase. — 24 April 1862.

deprived of good air, we do our best to get the mine clear of all stuff.

6165. But you very frequently find that the air is not so good as it otherwise would be, in consequence of the neglect of the workmen in clearing the levels? —Yes, and then we use our authority and make them clear the levels.

6166. Have you not been obliged to spale them for not clearing the levels ?—Yes.

6167. Therefore if the air is bad it is from their own neglect ?—Yes.

6168. Have you seen that frequently ?—Yes.

6169. You say that you have spaled them for it? —Yes ; but in this mine we set all our trammers and manage it ourselves.

6170. What is the worst ventilated mine that you ever had ?—The worst, I think, was a mine in Wendron ; there was the cold damp there.

6171. What was the name of the mine ? — Huel Ruby. It is a cold damp.

6172. Do you find that in the levels or in the pitches ?—All through the mine.

6173. Not a continuous damp, but after, perhaps, Monday morning, or something of that kind ?—It generally continues damp ; perhaps it is more so on Monday morning than when the men get to their places, and in the usual way of working.

6174. Did you find any difficulty in getting the men to work there ? — No, not a great deal ; we only worked there for about four years.

6175. What was the cause of that mine stopping, was it from poverty ?—From poverty ; it was a large lode and very poor.

6176. Could you account for the damp staying there ? — It was in the granite country, and the granite was in flat blocks, and the cold damp was always like a cloud of thick rain.

6177. Could not you dispel it by fans?—That might have been done, but it was never applied, and when you got away from the engine-shaft on to the course of the lode there was naturally cold damp.

6178. How long is it since that mine was suspended ?—About twenty years.

6179. What is the general age of your miners, working in this mine ?—I should think that the general age of those whom we have now in the mine is from 35 or 30 to 40.

6180. What do you suppose is the age of the oldest man ?—I think the oldest man that we have in the mine now is 50 years of age.

6181. Have you many of that age ?—No.

6182. Do you employ many boys ?—Not a great many.

6183. At what age do they go down ? — About thirteen years of age ; we do not allow them unless a parent wishes to have his own child with him, and then we let him do so.

6184. (*Chairman.*) What height do you drive your level ?—Seven feet high.

6185. You say that sometimes the men have complained of the accumulation of stuff; would one day's work stop up the level sufficiently to impede the ventilation ?—No.

6186. How often do the captains visit?—Every day. I have been down to-day to the bottom of the mine.

6187. If you saw stuff accumulating, should you not make the men remove it before it becomes injurious, as impeding the ventilation ? — We do so. We have nine trammers in this mine, and we send them where they are required. We know every day where the stuff has accumulated, and we send them at once to take it away.

6188. That is not done in all mines ?—No ; in a good many mines the men wheel their own stuff, and they put it off as long as possible.

6189. If the agent who was properly looking after the mine saw that, he would not let it accumulate, though it was the men's duty to remove it ?—No ; he would insist upon its being removed.

6190. Therefore the agent was to blame as well as the men, for leaving it to such an extent ?—We are sometimes obliged to be harsh with them to make them remove the stuff.

6191. Still if the agent had found fault with it in time it might have been removed ?—Certainly.

6192. But your plan you think better ?—Yes ; we have nine trammers in this mine, and we keep them at work.

6193. I suppose that it comes to the same thing in the end as to expense ?—Yes ; a man who takes his work under the idea that he must pay for that, must have more for doing it, and in the other way it is taken off.

6194. So that it is not more expensive to adopt the better system ?—No. I think the better system is of the most advantage both for the men and for the mine.

6195. (*Mr. Kendall.*) Did I understand you rightly, that in some mines men are expected to roll away their own stuff ?—Yes.

6196. And that in consequence of neglecting to do so at the proper time, a deficiency of air is produced ? —Yes.

6197. An agent may remonstrate again and again, and tell these men to clear their levels, and they neglect to do so, and at last, when remonstrance is in vain, you are at times obliged to impose a fine on them before they will do it ?—Yes.

6198. (*Chairman.*) But the agent could have imposed that fine on them before it got so bad as to impede the air ?—Yes, if he liked to take harsh measures, but he does not like to do so.

6199. But if it is injurious to the health, he ought to have done it ?—Yes.

6200. (*Mr. Davey.*) You are here provided with trams upon all your levels ?—Yes, all our levels are carried seven feet high and four feet wide all through the mine.

6201. But in many mines they have not trams ?— No.

6202. And it is in places where they are obliged to wheel out this stuff that they get this bad air ?— Generally so.

6203. (*Chairman.*) When men complain to you about anything, what is the first step which you take ?—We try to remove it.

6204. Do you go down and inspect it?—Yes, we go down first ; if any person objects, we generally go and see what is to be done. I would never put another man where I would not go myself.

6205. I suppose that in some mines, where you are driving to the end, it is difficult to supply fresh air, and to prevent the poor air ?—There we put in air machines, and take the foul air back, and throw in good air to them.

6206. Have you any air machines in this mine ?— Only one, and that is of no use ; we did apply that for a little while.

6207. Have you ever seen any mines where any other artificial means were employed for ventilation ? —Yes, water-falls.

6208. Do you think that you can ventilate any end which is driven however long by those artificial means ? —You can throw in air, and no better air can be produced than by a water fall ; a stream of water will produce good air.

6209. If you had this stream of water to what extent could you drive an end ?—It has been driven 150 fathoms, and if you put in your levels high enough you can put in air sollers at about a foot up from the bottom of the level.

6210. Do you think that a good plan ?—Yes, it will throw a double current of air ; it will come in one way and back the other.

6211. And you think that that ought to be done ? —Yes, where there are no chances of winzes, and where the levels are a long way off.

6212. We have been told that in many mines a winze has been driven to reach the level, but that in the mean time the air has been bad ?—Yes, then you can put in air sollers.

ST. AUSTELL.
Mr. J. Borlase.
24 April 1862.

6213. Can you cool the air if it is hot?—Yes; the fresh air coming in will drive out the other air.

6214. Sometimes when the air is very hot you think it advisable to apply air sollers?—Yes, if you are a long way off from any winze.

6215. (*Mr. Kendall.*) You have had very great experience as a working miner, what is your experience as to the supply of air when it once becomes impure; do they at once, generally speaking, apply artificial means to render it pure, or do they allow the men to work there for some time in impure air in order to save expense?—We get the things in as quickly as possible; when we go down ourselves, if we cannot stay we do not wish the men to do so, and we use means to remedy that evil.

6216. Do you know any case where agents have neglected to artificial use means when the men have complained?—None ever came under my experience.

6217. (*Chairman.*) But I think you said that you had not been employed in other mines?—No.

6218. (*Mr. Kendall.*) I speak of your experience not as an inspector but as a miner?—Yes.

6219. And you have worked in many mines?—Yes.

6220. (*Chairman.*) As a miner you have worked in poor air yourself?—Yes.

6221. Often?—Not a great deal.

6222. In what mines?—I do not know that I have worked in any worse than the one I spoke of just now, the Huel Ruby.

6223. But you said that there was a great deal of difficulty there?—Yes; we have a place here now, but it is unavoidable, we cannot help ourselves; circumstances, as the old man said, alter cases; we do not wish the men to stop down more than three hours.

6224. At what level is that?—At the adit level.

6225. You say that the men there can only work three hours?—They can work longer, but we do not request them to do so; we have been down there ourselves, and find that we cannot keep ourselves in it, and we are putting in air sollers to avoid the inconvenience; we have only one man there in 24 hours, so that the place has a long time to cool itself, and the air becomes pure.

6226. Are you putting in one of your air machines there?—We are putting in an air soller.

6227. (*Mr. Davey.*) How far is that from any shaft?—It is only about 50 fathoms from the shaft to the Callington mines; it is in an adit level.

6228. (*Chairman.*) How long have you been at work there?—Only a week, so that it is a mere nothing.

6229. Still you think that there are other mines where there might have been a great difficulty?—There might have been, but it has not come under my notice.

6230. From your great experience in working as a miner should you not think that there is in any mine an end where there is great difficulty in ventilating it?—In Trenow Consols I have worked somewhere about 10 years ago; we had a level there, and we had no opportunity of getting up and down in it because it is under the sea, and there I went down and put air sollers; it was 150 fathoms from the shaft, and after putting in the air sollers we had very good air, but the air was dead before that.

6231. From your experience it is your opinion that all ends, however poor or hot the air is, can be ventilated?—I think that there are means to be used.

6232. Then you would think that where means are not used they ought to be?—Yes.

6233. And whose blame is it if they are not used?—It is the agent's blame I should say; I should take the blame to myself.

6234. (*Mr. Davey.*) Did I rightly understand you to say that this adit level has only been working for one week?—Not more than about a week.

6235. And in that time you are putting in sollers?—Yes.

6236. (*Mr. Kendall.*) In the meantime one man is there in a day?—Yes.

6237. How long do you think it will be before you will get the sollers in?—He is putting in the sollers with him.

6238. (*Mr. Davey.*) He is not working in the end?—No; there is a shaft down 40 fathoms, and we have been down the shaft, and there are about two fathoms of water in; we have gone back to the adit to clear the tail of the audit.

6239. (*Mr. Kendall.*) And you are carrying in air sollers?—Yes, and removing the rubbish back upon the air sollers and getting a draught to follow the men.

6240. Then you are not actually working in the end yet?—No.

6241. But you are taking the very best mens that you can to get pure air for the men?—Yes, we are taking the very best means that can be adopted for the ventilation; the men are taking the air in with them.

The Witness withdrew.

Adjourned.

PENZANCE.

Wednesday, 30th July, 1862.

PRESENT:

The Right Hon. Lord KINNAIRD, K.T.	RICHARD DAVEY, Esq., M.P.
NICHOLAS KENDALL, Esq., M.P.	P. H. HOLLAND, Esq.
JOHN ST. AUBYN, Esq., M.P.	

The Right Honourable Lord KINNAIRD, K.T., in the Chair.

Captain ROBERT DUNSTAN further examined.

PENZANCE.
Capt. R. Dunstan.
30 July 1862.

6242. (*Chairman.*) I believe that since you appeared before the Commission you have been engaged in examining one or two mines?—Yes; several mines.

6243. Can you give us the result of any of your experience in those mines with regard to their ventilation?—I can just tell you what happened to myself in one of the mines in going down the mine.

6244. Will you name the mine?—Huel Emma, in Devon.

6245. (*Mr. Kendall.*) How long since is this?—It was the Friday after last Good Friday.

6246. (*Chairman.*) Were you employed to examine that mine?—At that time I conducted that mine—I was the manager of it.

6247. For what purpose did you go down the mine?—I went down to value the mine.

6248. On the day to which you have referred you went down that mine will you state to the Commission the condition as to ventilation in which you found that mine?—I will state the fact and you must judge as to the ventilation; there did not appear to be any want of ventilation; there was a very good current of air in the level above.

6249. Will you state the level?—It would apply in the same way to all levels under the same circum-

PENZANCE.

Capt. Dunstan.

30 July 1862.

stances; this was the 70 fathoms level. We were sinking a winze in the bottom of the 70 fathoms level. The winze had been sunk three fathoms, but the men had been keeping holiday during the Easter week. I did not know that they had been keeping holiday. I went hastily down the winze, and found that my candle became extinct in a moment. It nearly cost me my life; I had a very narrow escape of my life. We miners call it a damp. The damp had been formed during the absence of the men. There was no fault in the ventilation of the mine, because there was a fine current of air. It was between two draughts that the winze was sinking; there could not be any fault in the ventilation of the mine. How to account for the formation of the damp is beyond my skill.

6250. How did you go down?—By a rope, as we ordinarily do.

6251. (*Mr. St. Aubyn.*) Down a winze?—Yes.

6252. (*Chairman.*) What other men were there with you in the mine at the time?—The Captain of the mine was there and the miner who worked in the winze; but they were in the level, not down with me. I was the only one down in the winze.

6253. How far did you go down? Did you go down to the bottom as far as they had sunk?—Yes; I went down 18 feet only; that was the depth of the winze at that time.

6254. You landed at the bottom?—Yes.

6255. How long were you there?—Not a minute. I found my life going; of course I could not stay there. The candle became extinct when I got about eight feet under the brace, *i. e.* below the level; but I do not think that I was there two minutes.

6256. The candle went out before you got to the bottom?—Yes; the candle went out as soon as I touched the damp, of course; it acts upon the candle like water would.

6257. Had you any feeling as you were going down?—There was not time to tell. As soon as I got to the bottom I found my senses going away.

6258. How did you give notice to the men?—I knew what it was immediately, and I said "Pull me up."

6259. And they wound the rope up?—Yes. The captain took me by the collar and landed me on the brace.

6260. Did you lose your consciousness?—No; I never lost my consciousness; the time was too short.

6261. When you came to the level what did you do?—I lay on the level a little while, and then they raised me up and moved me forwards and backwards, and so on. It occurred to me that I had lost circulation for some time.

6262. Have you had any other such instances in the same mine?—Never.

6263. Is that called poor air?—That is called a damp. It may be the same in kind but different in degree; this is the extreme degree.

6264. How would you distinguish one from the other?—I could live in poor air but I could not live in a damp.

6265. How would you describe the difference?—It may be hard to describe it; the damp has lost all vitality. The poor air may retain a portion of vitality, so that a man may live.

6266. Is the candle the criterion for both poor air and damp?—No; a man can live when the candle will not burn. I have many times myself, in my experience, lived where the candle would not burn; but the effect of the damp, that is the carbonic acid gas, is beyond question to extinguish the candle instantly; it does not extinguish life quite so instantly, because in the air cells we retain a portion of life of course, and it must kill that life first. The candle is not the only criterion, poor air has a very bad smell with it which is very injurious to the miner.

6267. In your opinion, if the men had been working there that damp would not have accumulated?—No, of course not.

6268. What would have prevented its accumulating?—The circulation.

6269. Have you had any similar instance in any other mine?—No; not to the same extent.

6270. But have you experienced it?—Yes; in my life.

6271. Have you been down any other mine since where there was a similar case, where the air was visibly bad or poor?—Not to the extent of that.

6272. But you have been down other mines since you were before us?—Yes.

6273. Were these mines, which you have been down since, in Cornwall or Devonshire?—That mine was in Devonshire.

6274. Where were the others that you have been in where the air has been poor?—In Cornwall. The air is always bad in mines, more or less; it depends upon the ventilation.

6275. I suppose you mean in close ends, or winzes, or rises, or do you mean in all parts?—The bad air is not confined to close ends; what I have stated is a sample of it, because here was a small winze sinking only three fathoms under a current of air, and the air does not go down; the same air is at the back and the bottom. There is more bad air in general than people account for in consequence of air not rising or falling into the places where the men are working.

6276. In your opinion, if, instead of thus sinking a winze, it had been a rise, would the air have ascended?—No; it is just the same.

6277. Have you ever turned your attention to any remedy for that peculiar state of things?—We remedy it; we cause a circulation; that is the way in which we remedy it.

6278. (*Mr. Kendall.*) Do you fancy that the same kind of air as you speak of now would form in the back of a rise as it would down below?—Just the same. I have experienced as bad air in rising as in sinking.

6279. Did you ever experience the same deadly feeling as you experienced in Huel Emma?—Not to the same extent. In Fowey Consols I once experienced a very queer sensation in bad air.

6280. As I understand you, in Huel Emma you were in a drift where there was a pure current of air?—Yes.

6281. But in sinking a winze below that about 18 feet, during the absence of some men, there was an accumulation of what you conceive to be carbonic acid gas?—Yes.

6282. The only thing that I am rather puzzled at is your fancying that the same gas would form in the back; you think it would?—Yes; I have experienced very bad air in backs. I have seen backs in which I could not carry a light.

6283. Were you sick after you came up from that winze into the level in Huel Emma?—I was sick after I got into the level, and it relieved me.

6284. (*Mr. Davey.*) You have said that you have never seen an instance of it to the same extent before?—I have not.

6285. Have you seen anything like that damp in any other mine?—Yes; I have seen damps, but I was never down in them. I was caught here because I did not expect it.

6286. You went down before the other agent to inspect the mine?—Yes; he was with me as far as the level. I was putting prices on the work. I have seen damps, but we can generally see them with the eye, and then we do not go down into them; we send down a candle.

6287. How do you manage to see it; in what peculiar way does it show itself?—It would form like a film or a fog; you could see it like a white hoar fog.

6288. It is not very common to meet with those damps underground is it?—Yes it is. I have seen many of them; I never was in one before.

6289. You say that you never saw one in a rise?—I have been in rises where I could not carry a light up. What may have been above it I cannot

tell. I was never caught before as I was in this instance.

6290. You say that you could work where a candle would not burn?—Yes; I have found many places where a candle has been obliged to be stuck some feet behind me.

6291. If there is some rich ore, more particularly black ore, have you not been obliged to keep the candle some feet behind you?—I do not think that the ore has anything to do with it.

6292. (*Chairman.*) Have you known it?—No; and I have worked in all kinds of copper ore.

6293. (*Mr. Davey.*) Have you never found any instance where the richness of the lode injured the purity of the air?—I have never attributed it to that.

6294. When the men have left their tools on the Saturday, for instance, have you ever found that by the Monday morning they have been covered with a white damp?—I have never observed it.

6295. You have, of course, seen cases where they have been covered with green?—Yes; but that does not proceed from air.

6296. (*Mr. Holland.*) What does it proceed from?—It proceeds from the carbonate of copper.

6297. Do you think that there has been much exaggeration about the badness of air?—I do not know what has been said about it.

6298. Have you heard much about it?—The question has not been discussed. We miners know what bad air there is. I do not know what may have been said about it in other places. There is a great deal of bad air in mines.

6299. Is it very frequent?—Yes.

6300. In almost all mines?—In all mines more or less.

6301. In parts of all mines?—Of course.

6302. Not throughout all mines, or do you mean that?—When a main is taken up from a shaft and driven 10, 20, 30, or 40 fathoms the air becomes more and more foul of course, until there is ventilation.

6303. Is it a frequent thing in all mines?—It must be so from the nature of the case.

6304. (*Chairman.*) What is the difference between what miners call poor air and light air?—All poor air is light.

6305. (*Mr. Kendall.*) How many years altogether have you been working at mines as agent and as working miner?—Forty-five years, working man and agent.

6306. What age are you now?—In my 55th year.

6307. How is your health now?—Just as you see it.

6308. Is it not very good?—Yes, pretty good generally.

6309. Do you find many men much stronger than you are now?—I do not try them, but I do not find them so generally.

6310. Then the poor air has not hurt you much?—I was a tributer in Fowey Consols for 18 years.

6311. (*Chairman.*) How long have you been agent?—Eighteen years. I was seven years in the Bodmin mines, and three years in the Tamar mines in Devon on the banks of the Tamar. I have been a working miner 27 years.

The witness withdrew.

Note.—Liskeard, 21 Feb. 1863.—Your Lordship will please observe that there are many degrees of poor air in which the miner has to work, which is more or less injurious to his health; and although it is only in extreme cases of poor air or damp where the life of the miner is quenched out, yet I am of opinion, that a man cannot work in poor air without being injured by it to a lesser or greater extent, according to the amount of labour performed, and quantity of air inhaled.

I remain
Your Lordship's humble servant,
ROBT. DUNSTAN.

Captain RICHARD H. WILLIAMS of the Charlestown United Mines further examined.

6312. (*Chairman.*) I believe that at my request you have been making more particular calculations as to the way of working, the cost of putting up, and the general expense of your plan of ventilation by water, as described to the Commissioners on a former occasion?—I have.

6313. Will you describe your plan?—I sent your Lordship a tracing of it. I think that I described the height of the fall in my previous evidence. The water has a fall of 80 fathoms through a pipe of 1 inch and 1¼ inch diameter.

6314. (*Mr. Kendall.*) What sort of pipe?—Gas piping. The cost per foot of that pipe is for the 1¼ inch 5½*d.*, and for the inch 4½*d.* per foot. The pressure of water at the bottom of the fall of 80 fathoms is over 200 lbs. to the inch. The air launder in which a jet is placed is 14 inches square at the mouth and 8 inches at the discharge end, connected with which are galvanized iron pipes of 7½ inches diameter, costing 4*s.* 9*d.* a fathom. The quantity of water required to keep the machine at work is 11⅔rd gallons per minute. The cost of pumping that water up out of the mine is 1¾*d.* per hour. The temperature at the point of ingress of the air when the machine is at work is 71 degrees, that is taken on a mercurial gauge; at the point of egress it is 77 degrees. After the machine had been stopping six hours, the temperature at the point of ingress was 71½ degrees, and at the point of egress 78 degrees. From the point of ingress to the point of egress of the air it is 50 fathoms. There is no winze or communication for 50 fathoms. I believe that those are all the particulars.

6315. How do you ascertain the cost of pumping?—I make up the total number of gallons which the engine is pumping per hour; then taking the quantity of coals which it is consuming per day, I reduce it to hours, and then ascertain the value of the coals and bring it into pence, and dividing that by the number of gallons will show the cost per gallon of lifting the water.

6316. (*Mr. Holland.*) Does that include all the expenses; there are other expenses besides coal?—I take all the expenses. The items of expense in the pumping charges are, coals, candles, oil, tallow, gaskin, and cotton waste. I have worked this apparatus for the last 8 or 10 years myself.

6317. (*Mr. Davey.*) What is the name of the mine?—The Charlestown United Mines is where his lordship saw it; but I have also worked it at St. Austell Consols Mine.

6318. What mines are the Charlestown Mines?—Tin.

6319. Do you not always find the air very much cooler in tin mines than in copper mines?—Yes.

6320. (*Mr. St. Aubyn.*) Is the apparatus still working in both those mines?—Yes.

6321. (*Mr. Kendall.*) What is the greatest distance that you have ever been able to throw air with that machine?—The greatest distance that I have ever required it has been 100 fathoms; but I have put a rise through to the Charlestown mines 20 fathoms, and the commencement of the rise was 80 fathom off the point from which we took the air.

6322. From your jet?—Yes; and we put the rise through 20 fathoms under the lode.

6323. Whilst you were going through that distance of 80 fathoms and progressing with your rise, was the air invariably good while that engine was at work?—Yes; very good indeed.

6324. There was no complaint?—None at all.

PENZANCE.

Capt. R. H. Williams.

30 July 1862.

6325. There was no dull burning of the candle ?—Not the least.

6326. (*Chairman.*) Therefore, in your opinion, where a winze is driven merely for ventilation it would be much cheaper to put this pipe than to sink a winze ?—Yes.

6327. (*Mr. Davey.*) Have you ever tried it or seen it tried in a copper mine ?—No ; although about three years since I sent a part of the apparatus, namely, the rose and the cock part, to Captain Richards of the Devon Great Consols, and also a drawing of it ; whether he fixed it there and used it I do not know, but I believe so. The only difficulty which there is to contend with is having a point at which you can take off good air. There is no difficulty with this machine in throwing in the amount of air.

6328. But you must first get it from a shaft where there is an abundance of air to spare ?—Yes.

6329. (*Chairman.*) I presume that you can draw air to the jet at as great a distance as you can throw the air ?—Yes. For a very long time in Cornwall we have used wooden air pipes, and men in putting them in sometimes give them a blow too much, and they open the sides a little, consequently they have been so imperfect that I have found that in drawing air with the wooden pipes, we have been taking in air all through the level, so that we have had a very strong blast, at the end of the air pipe, but it has sent an impure air to the ment at work But if the pipes are tight, as we are now making them with galvanized iron, there is not the least difficulty.

6330. What is the cost of the galvanized pipe ?—I am giving 4*s.* 9*d.* a fathom for a 7½-inch pipe.

6331. You could make that to draw air down to the jet as well as to throw it ?—Yes. With the first machine which I put in I took the air 30 fathoms above the level. The machine is working 124 fathoms under the adit level.

6332. How far is the furthest end from a shaft and from ventilation, where this is at work ?—Fifty fathoms.

6333. How long is the smoke, after a blast, getting away from the end of the level where the men are working ?—We found that in five minutes the smoke was gone sufficiently for the men to go to work, and in 10 minutes the air was perfectly clear ; there was not the least smoke any more than there is in this room.

6334. (*Mr. Davey.*) In fact you force in air ?—Yes ; from the great velocity with which the air is sent through the pipe, it is as it were condensed ; the air goes in in a larger volume than its actual contents according to the weight of the atmosphere, from the great velocity with which it passes through the pipe, so that when it comes to the end it expands. I think that the forcing in of fresh air is advisable.

6335. (*Chairman.*) Have you any doubt that the process of ventilation would keep cool the end of a copper mine ?—I have not the least doubt of it, if the air could be taken away from a shaft.

6336. If a pure supply of air is introduced at one end behind the jet you think that it would be sufficient to cool a hot end ?—I think that it would cool it to a certain extent.

6337. (*Mr. Davey.*) Could you get air from the surface? In many of these copper mines it is impossible for you to get cold air to blow in, it is always hot ; could you draw air down ?—For a given distance I think you could.

6338. To what extent do you think you could do it ?—I have done it for 30 fathoms ; but of course we should have to force down the atmosphere, which has always a tendency to ascend. If pipes were constructed to the surface from the end this jet would not be required, because the action of the atmosphere would play of itself ; the rarified atmosphere of the mine would ascend through it, provided the pipes are continued up some 30 or 40 feet above the level of the top or colear of the shaft.

6339. (*Chairman.*) We want it the other way ?—This could draw out the air from the end instead of drawing it in. I have been in a mine to the 240 fathom level, to the bottom of a shaft where the air has been quite cold, and the men have been filling the kibbles with their jackets on. I have stepped from that shaft into an end where the temperature has been 97 or 98 degrees. No machine of any kind was used when I went into this end. The level was suspended. I have no doubt my jet would reduce the temperature and enable the men to work with comfort.

6340. (*Mr. Kendall.*) What mine do you refer to ?—Fowey Consols.

6341. And you have found that at 240 fathoms deep, in some of the main shafts, it was actually cold at the bottom ?—Yes ; I have come out of the main levels and have buttoned up my coat.

6342. (*Chairman.*) There your machine would supply good air ?—Yes ; but in the case of cross levels, perhaps the heat would be something like 80 or 85 degrees ; but then, I think that with this jet, blending the water with the air, cools it. The water is a sort of mist, it is something like a steam, the water is almost decomposed as it were, so that it cools the air. I believe that the air coming out at the end of the pipe is colder than that which enters it.

6343. (*Mr. Kendall.*) What is the distance of the jet of water ?—From 20 to 30 feet, and ejected with great force.

6344. (*Mr. Holland.*) Have you tried any other form of jet than that ?—I have tried larger ones ; but I find the size used to answer the best.

6345. (*Chairman.*) How long have you been at Charlestown United Mines ?—From their commencement.

6346. How many years is that ?—Since March, 1859.

6347. I believe that your men in blasting always use cartridges ?—Yes.

6348. They make them themselves down below ?—Yes.

6349. Have you ever had an accident from blasting ?—We have had no serious accident since the mine has been at work.

6350. Will you describe what was very nearly being an accident the other day ?—A pair of men had an upper hole ; that is to say, bored up in the back of the level, and the hole was very ragged, and they put their bag up, and put up three plugs of tamping. There was one man holding the bar and the other was driving it up, and they saw the fire come out of the hole, and they just fell back, and it went off bringing part of its burthen ; that was by cutting the fuse—the ragged hole cut the fuse.

6351. In your opinion, would not that have been avoided if they had used either a copper or a bronze tamping rod ?—Perhaps it would.

6352. Would it be desirable to have a tamping rod which would not create a spark by striking against the side ?—Yes.

6353. (*Mr Holland.*) Would that be a heavy expense ?—It would be very expensive in large mines. I have thought of a plan of having a copper tube the size of a tamping bar, and putting an iron bar in it so as to have an outer casing for the bar. I sent some iron to Birmingham, and had it galvanized, and tried some experiments with it, but I found that that galvanizing very soon rubs off. By the other plan we should have the stiffness of the iron bar to beat with and we should have the copper tube.

6354. (*Mr. Kendall.*) Have you any idea what the extra cost would be if you had the tamping iron cased in the way that you have suggested ?—I should say that one bar in that way would cost ten of the others.

6355. Even in this modified form ?—Yes.

6356. What is the cost of the present tamping iron ?—About 4*d.*

6357. Then I suppose that a copper one would be about 3*s.* 6*d.*?—I should think that it would.

6358. How long would that last?—I suppose that the copper would wear faster than the iron.

6359. But how long do you think that that might last?—I should that think it would last six months; a large portion of the copper would be still to be re-sold. This is only just an idea which has suggested itself to me, and I have been trying some experiments in the way of tamping bars lately. I think that a proportional length of the tamping bar might be made so as to have the full size of the iron up about 3 inches from the flooring, that is, the flooring to be 3 inches long, and to have the bar from the top of the flooring upwards its usual size. When the bar becomes short it is of no use, and is thrown away.

6360. Taking it in the most expensive form it would not cost much more than 7*s.* a year in order to ensure against striking fire?—I should not think that it would.

6361. (*Chairman.*) The men at present pay for the wear and tear of their tools?—Yes; we should have to be very careful, and perhaps make some different arrangements with respect to copper tamping bars, because copper is so easily disposed of.

6362. If you make any experiments will you furnish the Commission with the results of your experiments?—Yes.

6363. (*Mr. Holland.*) I understood you to tell us that by the use of a jet the temperature of the air sank from 78 degrees to 71?—No; it increased from 77 degrees to 78. It was only one degree increase of temperature after stopping six hours. Then the machine had been idle only six hours.

6364. Did you notice the temperature of the water?—No, I did not.

6365. Would there be much increased cost in bringing cold water down instead of the mine water?—That would depend very much upon circumstances; it would be a very great cost to be brought down from the surface in a very deep mine, but then you generally get at some point in the mine water moderately cool.

6366. Could not you get water trickling down the shaft, which is mostly surface water, at a temperature of about 40 degrees?—Yes; 40 to 45 degrees.

6367. If that was got it would lower the temperature in the mine?—Yes, undoubtedly, and there is no doubt that the air going out at the mouth of the pipe is of a much lower temperature than what is going in, because the water is cooling it. The water absorbs any excess of impure gases contained in the air.

6368. What is the quantity of air driven in?—About 2,000 gallons of air in a minute. I have only roughly estimated it.

6369. That 2,000 gallons of air in a minute is driven in by 12 gallons of water?—Yes.

The witness withdrew.

Note on 6338.—I cannot see any necessity of drawing down air from the surface, as all mines have good air in the main levels, although thick and hot. Yet a candle will burn well and bright. The water jet, as I have constructed it, so blends the air and water together, that it cools the air, and entirely frees the air of powder smoke; consequently, I think, if in the ends of our deep mines we could get the air equal to what is passing through the main levels, the evil would be cured, and the ventilation as far as practicable made perfect. I beg to call particular attention to the testimonial I have received of the effect produced by one of these machines I have recently supplied to Great Wheal Baddern Mine.

Captain JOHN TRURAN examined.

6370. (*Chairman.*) I believe you are the manager of the Ding-Dong Mine?—Yes.

6371. How many men have you working underground?—There are about 91 men working underground.

6372. The formation of the rock in your mine is of a peculiar character, is it not?—I suppose it is.

6373. The men work it not only by blasting, but also by chiselling?—Yes; they chisel out the centre of the lode.

6374. And then I believe they blast the sides?—Yes; there is a soft centre to the lode.

6375. How do the miners take it out?—The miners call the instrument a picker.

6376. It is in fact like a chisel?—Yes, it is; they chisel it out; they use a hammer, and cut away the centre of the lode, and bring it out, it being soft in the centre, and then they blast the sides.

6377. In chiseling out the centre part do they make a great deal of dust?—No doubt.

6378. (*Mr. Davey.*) Is the ground generally very dry?—Yes; it is generally very dry.

6379. What is the nature of this fair part of the lode?—It is steatite more particularly; there is a soft substance in the centre of the lode, and there is what we call antimony; but that I suppose will be found to be mica chiefly; it is a sort of oily substance softer than the surrounding rock and of a different character.

6380. You say that it is a sort of oily substance; would you get much dust from that?—The coating, as we call it, is very hard, and the end becomes filled with dust; that is, it rises very thickly about the mens' faces.

6381. Do you find that that dust affects the men much in their breathing?—Not in their breathing I think.

6382. How does it affect them?—It does not affect their breathing I presume immediately; but the miners are affected slowly. I do not think it is perceptible at first, not perhaps until several years have passed by.

6383. Are any of the men affected with what is called miners' disease?—Yes; some of them are.

6384. Do you attribute that to the dust?—Not altogether.

6385. (*Chairman.*) Two or three of your men have died lately, have they not?—Yes; not long since.

6386. Did you attribute their deaths to the dust or to any other cause?—We could not ascertain that, we had no means of ascertaining that.

6387. Is your mine well ventilated?—Yes; it is well ventilated as a mine.

6388. Are there not two or three other men who have been affected to whom you have given work on the surface?—Yes.

6389. (*Mr. Kendall.*) As I understand your evidence you have a very hard thin lode which you blast?—Yes; but sometimes the lode is not hard.

6390. You can blast it?—Yes.

6391. What is the average size of the lode?—About six inches.

6392. In the centre of this lode of six inches there is a part which is softer than the other parts of the lode?—Yes; generally.

6393. Then in order to facilitate the operation of blasting, and to make more room, you create a hollow in the centre of it by chiseling it out?—Yes; that is what we do.

6394. Is the soft part mineralized or not, generally speaking?—The soft part is generally mineralized, but not always.

6395. Do you generally save that or not?—We save that if it is mineralized.

6396. Take, for example, 10 holes; out of 10 holes do you save the part which is chiseled from one?—The chiseled part is not allowed to go with what is brought from the hole; the chiseled part is not mixed.

PENZANCE.

Capt. J. Truran.

30 July 1862.

6397. Is that because the chiseled part is generally speaking less mineralized than the blasted part?—No; it is more mineralized, but not always, it is generally said to be mineralized; it is of course selected; they take care of it; if it is not mineralized in the judgment of the miner then it is thrown away with the refuse.

6398. Generally speaking you would say that nine-tenths of what is chiseled out is thrown away with the refuse?—That would depend upon the character of it.

6399. Take an average of six months; is a quarter part of that which is so cut out saved?—I do not think that a quarter part in our mine is saved.

6400. Have you ever had that part which is chiselled out analysed in order to see what it contained?—Never.

6401. Then you do not know whether it contains noxious particles or not?—We presume that there is nothing more in it than what might come from the granite decomposing, or a little steatite; there is no arsenic I suppose, or rarely; no copper.

6402. It creates a small kind of dust being so very hard?—Yes; it is ground out sometimes; when it is hard we grind it out; the chisel reduces it to an impalpable powder.

6403. Do you conceive that the men must inhale some of this powder?—There can be no question of it, I think.

6404. But whether that amounts to inhaling anything more than the ordinary dust you do not know?—It is nothing more; we suppose so.

6405. Have you fancied in your own minds that this dust has been injurious or not?—It is our impression that it is injurious.

6406. What do the medical men say upon that point, or have you brought it under their notice?—Yes; it has been mentioned to them; but they have never been underground; we mentioned it to Mr. Bolitho.

6407. Have you ever known a case of this kind, that a man has become ill while employed in chiseling out this stuff, and has been then sent to some other part of the mine where he has become better, and then upon being sent back again to the first place has been taken ill again?—The last man who died in that neighbourhood was one of our miners; he was taken ill, and he remained at home for a little while. He came back again to work; we could not persuade him to give it up; and he then had a relapse, and he was very soon carried off.

6408. Have you ever had a man in your employment who was taken ill whilst employed in chiseling, and who was sent away under the idea that his illness was caused by that mode of working, to another part of the mine where there was no chiseling going on, and where he got better, and then returned to his former work and got worse again?—No.

6409. (*Mr. St. Aubyn.*) Have you ever known a man who was working in a bad part of the mine where his health suffered, and who was then sent to work in another part of the mine where his health improved?—They will improve if they have been working in a close part of the mine, and if they go afterwards into a part of the mine which is better ventilated. If they begin to fail a little underground you will find that they will improve if they come to the surface.

6410. (*Chairman.*) Do the men who work in the close ends suffer in their health?—Yes; there is no question about it, from working underground.

6411. (*Mr. St. Aubyn.*) Have you ever tried the plan of removing them to another part of the mine where there was less dust?—No; we do not suffer as to that; these men who died had not always been in the dusty part of the mine.

The witness withdrew.

Mr. RICHARD QUILLER COUCH examined.

Mr. R. Q. Couch.

6412. (*Chairman.*) I believe you are surgeon to several mines in the neighbourhood?—Yes.

6413. Have you been so for many years?—Yes.

6414. For how many years?—For 13 years.

6415. During that time have you turned your attention very much to what is termed the miners' disease?—Yes; very much.

6416. I believe, in the course of your practice you have for some time been making a record of such cases?—Yes; I have been making a record of every case that occurs.

6417. Will you be so good as to furnish the Commission with a copy of such record as you may have made?—I will.

6418. Do you consider that the disease called "miners' disease" is consumption or not?—If by consumption we mean tubercular phthisis, then I should say it is not.

6419. Does this disease end in tubercular consumption?—Very frequently.

6420. Have you had any opportunities of making post mortem examinations in such cases?—Yes; perhaps in 20 or 30; but it is very difficult to get them.

6421. But you have had some opportunities?—Yes.

6422. Is the opinion which you have formed as to this disease based upon the post mortem examinations which you have made, or upon the cases which have been brought under your notice?—The post mortem examinations have either confirmed or altered my previous ideas of the disease.

6423. Should you say that consumption generally prevailed in this part of Cornwall amongst other persons not miners?—Yes, I should. I think it does, but in considerably less numbers.

6424. In what district should you say it prevailed?—The district that I have particularly examined has been West of Hayle, and across the country to Marazion.

6425. *Mr. St. Aubyn.*) Do you mean west of a line drawn from Hayle to Marazion?—Yes.

6426. (*Chairman.*) Does that include any portion of an agricultural district?—Yes; St. Buryan and St. Leven, which are purely agricultural.

6427. Have you observed any difference with regard to consumption between the agricultural districts and the mining districts?—Yes; much difference.

6428. In which district does consumption most prevail?—Tubercular disease, or any disease approaching to disease of the chest, is occasional, and rarer in Sennen, St. Leven, and St. Buryan, than to the north of that which includes the mining district.

6429. Have you made any investigations as to the fishermen?—Yes.

6430. Have you observed that among the fishermen there is any tendency to tubercular disease?—Yes.

6431. Is that to a greater or less extent than amongst the agricultural population?—I think it is rather more than amongst the agricultural population; but considerably less than among the miners. I can furnish the data to the Commissioners upon which I found that opinion. I have made out the particulars for five years, and as I understand it, the fishermen are more liable to that disease than the agricultural population, and the miners are more liable to it than the fishermen; but I can furnish the Commission with the statistical proportions; they are already drawn out; a summary has been made for five years.

6432. You will be kind enough to furnish the Commission with that information?—Yes.

6433. (*Mr. Holland.*) Have you data to prove that there is an excess of tubercular consumption among fishermen as compared with agricultural labourers in this part of the county?—Yes.

6434. (*Chairman.*) Have you any data upon which you found your opinion that the miners are more affected with diseases of a similar kind?—Yes.

6435. (*Mr. St. Aubyn.*) Leaving the particular cause of death out of the question, do you find that the ratio of mortality is greater among miners than among fishermen?—Yes.

6436. Is it greater among fishermen than among agricultural labourers?—Yes.

6437. Independently of death caused by violence or accidents?—Yes; speaking of deaths from disease.

6438. (*Mr. Holland.*) Thoracic disease?—No, all diseases; I say that there is also an excess of tubercular disease among fishermen over agriculturists.

6439. And amongst miners over fishermen?—Yes.

6440. (*Chairman.*) How would you account, in the first place, for the excess of the disease amongst miners, and then amongst the fishermen?—It must arise, I think, from the nature of their occupation. It is not confined to this district; but it is so throughout the county. I have generally supposed (but it must only be taken for a supposition) that it arises from undue exposure, and the impossibility of getting that shelter and other comforts which fishermen are unable to get as compared with agriculturists.

6441. Then what should you say with respect to the miners?—I think that the occupation of the miners predisposes them to diseases of the chest; but to enter minutely into that subject I should have to go into the record of my cases.

6442. (*Mr. St. Aubyn.*) The general conclusion at which you have arrived is that the difference in the ratio of mortality among these labouring classes is caused by the nature of their occupation?—Just so.

6443. (*Chairman.*) Will you be kind enough to describe to the Commissioners the nature of the miners' disease as far as it has come under your observation?—The first indications of ill health are very obscure, extremely gradual in development; so gradual that the miners themselves never acknowledge it. You will find that the first symptom, perhaps, of the disease will be pain at the pit of the stomach, or an inability to climb the ladders with the usual rapidity; the muscular power becomes less than it has been in times past; and then, if I keep them at grass for a fortnight or three weeks, I find that they regain that muscular power, and they say that they are able to climb the ladders again with the same elasticity as before, and they will go on in that state for years without any apparent diminution of health, if the air be good.

6444. You say that they will go on in that state for years; but if they return again to mining do they suffer a relapse?—Yes.

6445. Do you, as a medical practitioner, when they come to you suffering from ill health, advise them to give up mining for a time?—Frequently, and especially if I find they are not improving under treatment. I find also—for I have had 1,100 or 1,200 men weighed—that if, before going down a mine, they are weighed in the same dress in which they come to the mine, and then work underground for six or eight hours, and are again weighed in the same dress, they have decreased in weight very considerably on coming to the surface, and if, the next day, I find that they have not regained the weight which they lost the day before, I advise them immediately to stop.

6446. That is in the case of those men who consult you as patients?—Yes; it is not the case with all miners that they regain on going down the second day the weight they lost the day before; but taking the average of all the mines in this district, or the 16 or 17 where I got the captains to weigh the men for me, and taking into account the shallow workers with the deep workers, the decrease is about 3 lbs. and 3 quarters; but if the deep workers only are taken into consideration the decrease in weight then amounts to very nearly 6 lbs. and sometimes more than that. With regard to the captains who go underground only occasionally, I find that they sometimes decrease in weight from 10 to 13 lbs. in the same number of hours.

6447. What is the greatest decrease that you have known to take place in the weight of a working miner?—About 7 lbs.; but in that mine they have been going from a shallow level to a deep one; after that the decrease in weight becomes greater; before that the decrease has not been so great. The nearer they are to the surface the less they decrease in weight, I think. I have small books provided I have arranged in a tabular form. I have given them to the captains, who have weighed the men on going down, and then entered their names and weights, and when they come up again they have weighed them again.

6448. The utmost loss of weight which is recorded is 7 lbs. in the case of a labouring man; what has it been in the case of a captain?—In the case of Captain Thomas Roberts there was a decrease in weight of 10 lbs., and in the case of another person the report made to me showed a decrease of 13 lbs., but he was a very stout man.

6449. Do you know at all the depth at which the man worked who lost 7 lbs. in his weight?—He worked, I think, at about 180 or 200 fathoms in a close end.

6450. Do you think that if a man worked in a close end at a shallow level, there would be any difference as compared with a man working in a close end at a deep level?—I think that they would lose more weight in a deep level.

6451. Should you attribute that to the exertion made in ascending?—It is much hotter below, and they lose more weight in proportion to the closeness of the end as well as the depth of the level; there are many circumstances to be taken into consideration. I think they lose it chiefly in work. In hot deep mines they lose more in reality than I have stated, for a large supply of water is sent down and much is drunk by the men.

6452. In any of the cases in which you have had the men weighed was there a man-engine to ascend by?—No; they all climbed up the ladders.

6453. Do you think that that would tend to diminish their weight?—I find that in a case where there is a man engine, at Wheal Reeth, the boys actually now get out of the man-engine and climb up between the lifts in order to give themselves a little exercise.

6454. (*Mr. Kendall.*) As I understand you, it is beyond all doubt that the miners, as a body of men, are less healthy than either the agriculturists or fishermen?—Very much so. Even healthy miners are more frequently on the sick list than other labourers.

6455. Does that bad health, on the part of the miners, in your opinion, arise from simple causes or from complicated ones?—I believe that there are several causes to which it is to be attributed, but chiefly to bad ventilation.

6456. Amongst them I presume you would enumerate the climbing up the ladders?—Yes.

6457. And perhaps also the want of drys?—Yes; the want of drys at the surface.

6458. And then, perhaps, also their mode of living, too many of them huddling together in small rooms?—Yes.

6459. Can you suggest any other causes which you think affect their health?—The first is, I think, a want of ventilation below the surface; that I think lays the foundation for all the mischief. That is why I think that the men, apparently in the enjoyment of good health, become blanched, their skin becomes sallow, and frequently assumes that kind of appearance which Dr. Addison calls the bronzing of the skin; and on examination, in several cases in which they have sustained injuries to the hand from jammings, I have placed the blood under a microscope, and I have found that the red corpuscles are very pale, and very much shrivelled, showing a deficiency of blood power. That is before they give any indications of disease, or before they complain.

6460. Would that arise as much from bad ventilation in their dwellings as from climbing, or from the

PENZANCE.

Mr. R. Q. Couch.

30 July 1862.

perspiration being checked, because there were not proper drys for them to go to?—I put it down principally to their working at deep levels with bad ventilation, and for this reason I find that the engine-men, and those who work at the surface, and whose mode of life otherwise is of the same character, do not suffer from the same diseases.

6461. You have been, I believe, underground a good deal?—Yes, very frequently, and I find that the men are better taken care of than I was led at first to expect.

6462. Have you been through deep levels?—Yes, and think that much mischief is caused by the men themselves, by their throwing the "deads" or rubbish in the levels, so as to block out the ingress of fresh air.

6463. Is the natural ventilation fairly good in the mines which you have seen?—There is no system of ventilation in any mine I have seen. Where there are many shafts, the ventilation is very good, except in "ends" or backs of levels and winzes, as well as crop cuts. In Botallack, which is worked under the sea, there is a diagonal shaft going to the bottom. By this means, the ventilation is much better than before. But it is impossible thoroughly to air all places so situated. In one mine where there was only one shaft a few years since, the ventilation was dreadful, and all the men had failing breath, and on going to other and colder mines died from pneumonia and phthisis.

6464. How did you ascertain that the ventilation in that mine was bad?—I first enquired of the men, and took their accounts when they came to consult me without any reference to any enquiry afterwards; and they invariably described the ventilation as being excessively bad, as judged by their own standard of the "candles would not burn." This mine was unfairly bad.

6465. What do you mean by the terms "unfairly bad"?—I mean that there was a single shaft, and the mine was worked down into a deep pit, the levels running east and west of it, without any other ventilation, and very few winzes; and the health of the men was very bad.

6466. That would appear to have arisen from a desire to save money at the expense of the men's lives?—I will not give any opinion upon that; but I should hope not. The adventurers lived out of the county.

6467. You say that there were no winzes, or very few?—There were very few, and only one shaft.

6468. (*Chairman.*) Who was it that prevented you going down that mine?—The gentleman is dead now; but I could never get access to the levels, and even after I was appointed surgeon I never could get an opportunity of going down nor obtain any return of the ages of the men; in fact, I could get no information from the mine, except what I got from the men.

6469. As a medical man, you had no real opportunity of judging of the disease which afflicted the men?—Yes, I had; but I had no opportunity of judging of the state of the mine except from the reports of the men.

6470. Do you consider it your duty to enquire into the state of a mine?—When I find that there is much disease in it I do; and I must say that the captains are always willing and anxious to remedy any defect when it is mentioned to them.

6471. You make it a point of giving them notice?—Yes. I always talk to them about it, for the purpose of making alterations.

6472. (*Mr. Kendall.*) Have you any suggestions to make to the Commission with a view to improving the ventilation in the mines?—There are many suggestions to be made. Some of the miners are injured by accidents, for instance, by explosions; and I have tried to invent something in order to remove the tamping from the holes, but they object to use anything new, and will not even use what has been proved to be good; the captains have often to complain.

6473. What is it that you would substitute?—Instead of taking the tamping out in the usual way, I would use a thing something like a cork-screw, to be worked in the same way that a carpenter works an auger, to go down to the bottom, and then drawing it out almost like a cork from a bottle; you may not take all of it out, but it would be so loose that water could be thrown in on it and so prevent explosions.

6474. (*Mr. St. Aubyn.*) You have mentioned the circumstance of the men losing a great amount of weight in going down a mine, do you weigh them yourself?—No; the captains of the mines weigh them, or the managers of the mine; the local agent of a mine.

6475. Have you every reason to believe that the weights were correctly taken?—I asked them to do it to avoid doing it myself, and that they should make their own returns.

6476. Are you just as sure that they were correctly taken and recorded as if you had done it yourself?—I was weighed myself two or three times in their scales, and I found that I was the same weight with the exception of a quarter of a pound that I was in Penzance before I left.

6477. Do you believe that their scales were correct?—Yes; and their weights.

6478. You have no reason to doubt the correctness of their reports?—No.

6479. You have mentioned a number of causes of disease which are peculiar to miners, and with regard to the miners' disease, which you cannot call tubercular consumption, you think that that is chiefly produced by bad ventilation?—Yes.

6480. Are not miners subject to diseases of the heart?—Yes.

6481. To a considerable extent?—Not to such an extent as you might expect to find. I found those cases more at Camborne than here, where the mines are deeper.

6482. The deeper the mines are the more you find diseases of the heart prevail?—Yes; I would say affections of the heart.

6483. In mines where the men come to grass and go down again by ladders, would not the climbing rather produce affections of the heart?—Yes, I should think so; certainly the climbing would aggravate the disease if it had once set in.

6484. Are you not of opinion that climbing great heights by ladders from great depths, is calculated to produce an unhealthy action of the heart?—Yes. I think that the blood of the miner is decidedly in a state of impurity during the operation of climbing; while in the act they draw themselves up by their arms, and not by their feet; and then that impurity of blood is rendered still more impure by the cessation of respiration during the act of climbing; so that the state of the blood is rendered more unfit for circulation by the absence of respiration in the ascent.

6485. Then this action of the heart, caused by climbing supervening on the unhealthy state in which the blood of the miner is for want of ventilation aggravates disease?—Yes.

6486. Do you not think that any system by which climbing from great depths could be avoided would materially improve the condition of the miners?—Yes; and I may mention a case that occurred only a day or two since. A man was working in Wheal Reeth in a very close end, and disease of the chest was coming on. He went to work and was put in another place where he was lifted by a man engine, and he recovered, I should think, in less than a third of the time that other men labouring under the same disease would have recovered in. They were ascending to another shaft. I find that continually the case where the man-engine is employed, the men do not suffer so much, and they recover more quickly than they do when they have ladders to ascend.

6487. Have you put down in writing any observations as to the comparative state of health of miners in places where the man-engine and the skip are used and where the men ascend by ladders?—The man-engine has been so recently introduced into this district that I think it can hardly have produced any effect upon the health of the miners engaged; but they recover better and more quickly where the man-engine is used than without.

6488. (*Mr. Holland.*) After their lungs have been affected?—Yes.

6489. (*Mr. St. Aubyn.*) The skip being of still later introduction you have probably not made any observations upon the effect produced by its use?—Very few men come to the surface in the skip in this district.

6490. Do you attend any mines where they use the skip?—Yes, Wheal Reeth; and I see many men from Levant, where they employ a skip.

6491. You say that the men do not use it, do they prefer coming up by the ladder?—I do not know why, but there has been an objection and a difficulty in getting the men into the skip.

6492. Do you mean to say that where the skip is in use the men do not use it but come up by the ladders?—No; I have no experience upon that.

6493. You stated I thought in a former part of your evidence that they sometimes got out of the skip?—No, out of the man-engine.

6494. Upon the whole you are decidedly of opinion that either the man-engine or the skip, if they were introduced, would materially improve the condition of the working miners?—I think so.

6495. (*Mr. Davey.*) You did not give any reason why the men left the man-engine in order to ascend by the ladders?—They said that they found themselves so cold from coming from a deep level between the lifts, that they would get the advantage of running up the ladders until they reached the next lift to get themselves warm.

6496. It was not done from distress?—No; from mere wantonness, and only by boys.

6497. You stated just now that you had not found that the engine-men were affected in the same way as the men working underground?—Yes.

6498. I believe it is generally the case in Cornwall, when a man has been injured underground that he is set to work at the engine?—Yes.

6499. And the question is whether by working at the engine, and therefore at the surface, he becomes benefited?—He does become benefited. There are some cases in this neighbourhood of men who have been young, and have been so benefited when they have gone to work at the engine. The only indication of miners' complaint has been blood in the expectoration at intervals and from cold.

6500. How long have you been practising among the miners?—I think about 13 years.

6501. Have you found any difference in the health of the miners during that time?—Yes; I think that they are improving.

6502. Do you think that they are improving much?—Yes. I think that the young men do not show the same indications of disease that the old ones have done.

6503. Do you think that the miners are degenerating as a class?—I do not think that a period of 13 years is enough to indicate that.

6504. You say that the men lose weight in going up and down a mine, and that the loss of weight in the captains has been much greater than in the working men?—Yes.

6505. How do you account for that?—In the case of the captains, from their going underground so rarely as compared with the men. I do not now speak of the underground captains, but of the managers or residents of the mines who go underground perhaps only once a week to examine the mine.

6506. You do not speak of the captains?—No.

6507. Do you consider that they are in a worse condition from want of exercise?—They are very much stouter from not going underground. You rarely find an underground miner with any superfluous fat upon him.

6508. You have stated that you have been frequently underground, do you ever see much dust rising?—In the dry ends I have; but generally speaking, they have been wet.

6509. As a general rule I suppose the men cannot be injured much by imbibing the dust in working?—Under the microscope I discover dust, or at least I discover minute particles of granite and of other rocks where they have been working, mixed up with the sputa. Dr. Peacock was down here, and I have at his suggestion taken the expectoration and placed it under a microscope, between thin layers of glass, and I have found minute particles of stony dust.

6510. That could not have occurred except in very dry ends?—No, at least I presume so; where the rock is struck, and it is dry, although it may get wet afterwards, a blow will produce a dry cut, and dust may arise then. But very frequently in the expectoration of the miners we find these minute particles of dust, as I may call them.

6511. (*Mr. Kendall.*) Did you ever analyse the ordinary expectoration of a man on a dusty day?—Yes, and I have found dust there as well, but not angular particles of stony.

6512. (*Mr. Davey.*) Are you aware whether the places in which those men worked were wet or dry?—No.

6513. (*Mr. St. Aubyn.*) Have you examined the expectoration of those miners who have been working in wet ends?—Yes.

6514. Have you found an absence of dust in their expectoration?—I cannot say that I have particularly noticed it; I have not entered it, whether they have been working in one or the other. I have given them a bottle with a screw top, and I have said "When you get to the surface and you find any "expectoration is coming up, put it into this bottle, "and screw it down, so that no dust from the sur-"face shall get into it;" and allowing for some getting in, yet the quantity has been greater than with the ordinary precautions would have entered into it.

6515. You say that you have examined the expectoration of miners who had worked in dry ends, and there you found minute particles of granite?—I should say that I have examined the expectoration of miners without reference to whether they worked in dry or in wet ends, and frequently find in the expectoration angular dust.

6516. You cannot say from your own microscopic examinations whether there is more dust in the expectoration of those who have worked in dry than in the expectoration of those who have worked in wet ends?—No, I cannot.

6517. (*Mr. Holland.*) Are the mines here chiefly granite mines?—Yes, chiefly so; just on the borders of the slate with the granite.

6518. Although the floor of the level might be wet the rock itself would be dry?—Yes; but I have not made sufficiently minute observations as to the proportion or quantity of dust in a particular mine; I have not noticed it.

6519. You have stated that the miners' disease terminates in phthisis, is that a general observation?—It is a general observation. I do not say that every case terminates in phthisis, but only occasionally; I look upon miners' disease not as consumption, that is tubercular disease, but that the miners from their habits are so strongly predisposed to it that unfavourable circumstances will develop it.

6520. You are no doubt aware that there is somewhat less than the average amount of consumption among miners below the age of 30?—No, I do not know that.

6521. Assuming it to be the fact that there is less than the average amount of what is called consumption among miners below the age of 30, does not that

PENZANCE.

Mr. R. Q. Couch.

30 July 1862.

seem to imply that miners are not more liable to consumption than ordinary men ?—I doubt the fact.

6522. But assuming that to be the fact ?—I doubt it.

6523. Do you doubt the accuracy of the returns made by the Registrar General ?—I doubt the fact of the Registrar General knowing whether it is tubercular disease or not.

6524. Is hemoptysis a common symptom in miners' consumption ?—Yes ; I have had eight cases since this day week.

6525. Take, for example, 100 cases, would it occur in 50 of them ?—No, I think not.

6526. Would you not find hemoptysis in 50 cases out of 100 of common phthisis ?—No, not here.

6527. Do the miners suffer much from hectic in the advanced stages of miners' consumption ?—No.

6528. Have they often symptomatic diarrhœa ?—No.

6529. When the disease is tolerably far advanced in miners and their occupation is changed, is not the disease frequently suspended ?—Yes.

6530. Is that commonly the case in ordinary consumption ?—No, I think not here ; when you speak of consumption I presume that you mean tubercular disease ; I think where it is pretty far advanced it occasionally will be suspended, but in the majority of cases it will not be, it will progress.

6531. At what age do miners generally become consumptive and die ?—I stated just now that the tendency of miners' disease was not consumption in the ordinary meaning of the term.

6532. At what age do the miners die of what is called miners' complaint ?—That will depend upon the mines they are working in and the influences they are under ; the average age, referring to deaths from all causes, in this district is about 44 to 47.

6533. (*Mr. St. Aubyn.*) That is amongst miners ?—Yes.

6534. (*Mr. Holland.*) That is about the age at which miners' consumption is most fatal ?—Yes.

6535. Ordinary phthisis is much more fatal early in life, is it not ?—Yes.

6536. Ten or twenty years earlier ?—Yes, very frequently.

6537. Does that seem to show that miners are peculiarly liable to phthisis ?—When you take that in connection with this, that the miner who is subject to the miners' complaint takes cold, and I have a case of that kind now. A young man at St. Just, called Harvey, was labouring under the miners' disease, and I had examined him not very long before as a matter of enquiry ; he was a healthy miner and I think about 25 or 26 years of age ; he was working in a shaft where there was good air, he having been placed there in consequence of having worked in a foul end where he had got the miners' disease, it was developing itself, not consumption ; he then fell from a board into the water, he caught cold, tubercular disease immediately developed itself, and he died.

6538. Have you been so fortunate as to be able to make many *post mortem* examinations ?—Not so many as I could wish to have made.

6539. How many have you made ?—Not more than 30.

6540. In how many of those 30 cases do you think there was tuberculous deposit ?—I should think in perhaps about half or rather more ; I should observe that they were selected, or at least I rather pressed the matter because I thought there was tubercular disease. The first few cases that I examined were tubercular, and in those cases that I thought tubercular, I rather pressed to have them, and I found that they were so.

6541. The number of cases in which there was tuberculous deposit would be above the average ?—Yes, it is not a fair average.

6542. The conclusion I should draw would be that tuberculous deposit was the exception and not the rule in miners' consumption ?—I have stated distinctly that tubercular disease is not the result of the miners' occupation, but it is the effect of it under unfavourable circumstances afterwards.

6543. But that effect is produced in the minority of cases and not in the majority ?—I wish distinctly to be understood to say that I do not think tubercular disease is the necessary result of the miners' occupation.

6544. (*Mr. Kendall.*) You have stated that you have sometimes heard of the men leaving the man-engine and getting on to the ladders. and then again ascending by the man-engine ?—Yes.

6545. I suppose that they get stiff and cold coming up by the man-engine ?—Yes.

6546. Is it not probable that in some cases the man-engine may be almost more dangerous than the ladders when the men come up from very hot ends through a cold shaft without having any exercise ?—No. If the drys were good at the surface I think that the man-engine would be a greater benefit, but the man-engine is a benefit under all circumstances.

6547. (*Mr. St. Aubyn.*) You do not think that the chance of catching cold while standing on the lifts would do away with the advantage that is derived from the man-engine ?—No; I think that the man-engine is a great benefit to them.

6548. (*Chairman.*) Is it not important to have changing houses near the ladder ways ?—Yes.

6549. (*Mr. St. Aubyn.*) You have mentioned the case of a young man whom you examined and found perfectly free from tubercular disease ?—Yes.

6550. He tumbled by accident into cold water, and rapid consumption set in, from which he died ?—Yes ; it was not immediate, he had an attack of inflammation in the upper part of the lungs, which in some six or eight weeks ended in tubercular disease.

6551. His death resulted from the effects produced by falling into cold water ?—Yes.

6552. Do you think that real consumption set in more quickly perhaps on account of his predisposition to it from having worked underground ?— Yes ; and I give that as an illustrative case.

6553. Have you observed in the mines with which you are connected that the drys are kept in good order ?—Yes ; the agents are erecting new ones in some of the mines with which I am connected.

6554. Do you find that there is generally a disposition to improve the condition of the mines ?—Yes ; if I speak to the pursers I find very little difficulty in getting my suggestions attended to. If you speak to the underground captains they sometimes forget. It is not done by the adventurers.

6555. If proper representations are made in the proper quarter do you find that there is every disposition to provide for the comfort of the miners ?—Yes.

6556. (*Chairman.*) Are those mines with which you are connected legitimately worked, or are they jobbing mines ?—There are some of a jobbing character ; but in others the shares are so large that they very rarely change hands.

6557. Have you found any difference, on proper representations being made, in the attention that is paid to them ?—Yes ; I think that those persons who are *bonâ fide* miners take more care of the health of the miners than persons who are in to-day and out to-morrow.

6558. You have stated that you think there has been an improvement in the health of the miners, judging by the younger ones ?—Yes.

6559. Do they go at a younger age to the mines now than they did formerly ?—No. I think that they go underground at 10 years of age. I have known two cases in Balleswidden go underground at eight years of age ; but that is an exception. I inquired of Mr. Young, at St. Ives, and he told me that the health of the miners was the same precisely as it had been when he was a young man ; he is connected with the old deep mines ; but his experience and mine do not agree on that point. I find the miners better in health.

6560. Do you find their health better in the shallow mines ?—Not merely there ; but in the new mines.

6561. The experience of Mr. Young was that there was not an improvement ?—Yes.

6562. Is the health of the miner likely to be more affected if he goes underground at the age of ten, or if he goes underground at the age of 17 ; in other words, would he become more accustomed to it by going underground younger ?—That varies very much. If an agricultural labourer goes underground at the age of 23 or 24, and works in a deep part of the mine, he is more rapidly affected than a man who has been working in the mine from a boy.

6563. As far as you can judge, the circumstance of going underground at 10 years of age rather acclimatizes the miner than otherwise ?—Yes.

6564. Have you arrived at any conclusion as to the ages of the working men in the mines ?—I have published one or two short papers on that subject, from the returns I have obtained at the request of Mr. Fox ; he wished me to publish them to the Miners' Association, and I think I may say that the average age of the males engaged in underground work is rather below than above 30. At St. Just I find that the average age, including the timber men, is 28 ; but excluding the timber men, the average age sinks down to about 26 and 27. Some time ago a gentleman connected with mining, said that he could not believe it. His son was appointed under the Census Act to take the census of that district, and I asked him to make a return, which he said he would do. He told me afterwards he was sorry to have to report that the average age of the whole of the miners in St. Just was 26.

6565. The average age was below what he expected to find it ?—It was below what I have stated. I have taken four or five of the most important mines, and left alone the others in order to save trouble.

6566. (*Mr. Kendall.*) You have given the average age of all the working men and boys ?—Yes.

6567. How low does that go down ?—Down to the age of 10 ; but I think there ought to be something put in the balance against that, and for this reason, that a number of able-bodied men from St. Just have emigrated to California and to other places ; but then I think that the average age of the working miners would be below 30 in this neighbourhood.

6568. (*Chairman.*) Would any difference, do you think, be made in climbing the ladders if the space between the bars was 10 or 12 inches ?—I think that the smaller the space between the bars the better.

6569. Can you state from your own knowledge what amount of money the men contribute to the club ?—I do not know exactly ; but I am acquainted with the working of the clubs.

6570. Referring to the working of the clubs in the mines with which you are connected, is relief given in case only of accident, or in case of sickness also ?—It is only given for external and visible hurts ; that is the phrase which they employ.

6571. In all the mines with which you are connected that is the case ?—Yes.

6572. Is the club-money left entirely in the hands of the pursers to manage ?—Yes. There is one mine where, I believe, the club itself is in a state of bankruptcy ; but still the adventurers pay the money, although they have no money in hand.

6573. When a man is laid up suffering from miners' disease, does he receive no assistance ?—I believe not.

6574. Then what means has that man of obtaining a sufficient supply of necessary food when he is out of work ?—I suppose the union.

6575. In the cases of the men whom you have attended, do you think that they would have recovered sooner if they had been supplied with more nourishing food during the time they were out of work ?—I have adopted the plan in the mines with which I am connected, of very frequently requesting the captains just before the pay-day or the account, to have soup and broth sent to these men, and in case there should be any meat left behind, that it should be given to these sick men.

6576. There is no regular provision made for a man if he is out of work ?—No.

6577. Do you not think that such a provision would be very desirable ?—Yes, most desirable.

6578. (*Mr. Kendall.*) You are aware that in every mine there is a club, and you have known many mines which have stopped. Do you think, upon the whole, that the club is a matter of profit to the men or to the adventurers ?—I am afraid that it is to the adventurers in jobbing mines.

6579. Do you know of any case in which a mine has stopped working when the club money has been divided ?—I know of a case in which a mine has stopped when the club money and the doctor's money, a surgeon never having been appointed, have been thrown back among the parties to pay for a dinner that was given at the closing of the affair.

6580. I suppose it was a small amount ?—No ; it went pretty well to pay for most of the expenses.

6581. (*Mr. Davey.*) You do not know of any instance in which the club-money has been divided among the men ?—Never. But I have made no enquiries on the subject.

6582. (*Mr. Kendall.*) I suppose there would be very great difficulty when there was a balance in hand in fairly paying it back to the miners, as they are a shifting population ?—Yes ; but it might be distributed among the sick connected with the mine at the time of its stopping, or given to a general fund for the benefit of miners.

6583. (*Chairman.*) Would it not be desirable that the club money should be used in affording relief in case of sickness, and not only in the case of accident? —Yes. I think it should be applied in the case of all sickness, as a good deal of that arises from the nature of the occupation of the miners, and when that is the case, I think that the club money should be used in affording relief in the one case as well as in the other.

6584. (*Mr. Davey.*) Would you not require a much larger sum to do that ?—No. There are some mines in this neighbourhood, which, so far as the club is concerned, are in a state of bankruptcy ; but in others, I believe they have 400*l.* or 500*l.* in hand; and if the club was made a combined club the redundancy in the one would counterbalance the deficiency in the other.

6585. If they began to work in a new mine, then, of course, the payments to the club would increase ; but if it were a mine that had been worked for many years, so many demands would be made upon the club that it would become bankrupt ?—It might, if accidents were numerous.

6586. (*Chairman.*) Would it not be very desirable that something in the nature of a dispensary should be established at which the men could obtain relief ? —Yes. There is one class of diseases to which no reference has yet been made, and that is diseases of the stomach. I have found in my experience that before any disease of the chest occurs the stomach becomes disordered, and the miners complain of pain in the head ; to such an extent does the stomach become affected that they cannot bear any pressure. This has struck me besides disease of the chest, and there is a general disinclination to work on the part of the miners, for there is great prostration of the nervous system ; the pulse beats not more than 48 or 50 in a minute, the depression is great. I believe it first arises from the stomach.

6587. From breathing bad air or poor air the miners become first affected in the stomach ?—The first visible effect has been in the stomach. The appetites of the miners then become very much impaired, and they are incapable of taking that food which is fit for them, and in fact, the foundation of very serious illness is laid.

6588. (*Mr. Kendall.*) Are you of opinion that their occupation produces indigestion ?—It is not that ac-

PENZANCE.

Mr. R. Q. Couch.

30 July 1862.

tually; there is actual disease of the stomach, and they cannot bear any pressure.

6589. Is it inflammatory?—It is excessive tenderness.

6590. (*Chairman.*) In this district do the miners take down into the mines with them cold pasty or bread and butter?—They sometimes take down with them bread and butter, and sometimes cold pasty.

6591. But that is a heavy thing, is it not, for the stomach in a delicate state?—Yes, it is. There is one question which Mr. Holland proposed to me this morning, as to which I think some misunderstanding has occurred, in relation to the mortality of the children. Mr. Holland supposed this morning, when I referred to the mortality of children below five years old, that it was a low mortality upon the births; but on looking at my papers I find what I suspected, that that is not the case. I find in my reports that a certain number of children belonging to miners die below five years old, and therefore it is a per-centage upon the deaths of the children, and not upon the births of the children, to that statement I adhere. Many die very early; but if they survive that age, they live on in health.

6592. With regard to the dietary of the miners, the agricultural labourers, and the fishermen, which of the three, in your opinion, lives the best?—The agricultural labourer. He has a stomach to digest his food; but the miner could not digest what the agricultural labourer does.

6593. Which of the two spends most money upon his food?—I believe the miner does.

6594. Do you think that the miners are amply fed?—I do not think so.

6595. I mean considering the work they do?—I do not think that they digest the food which they get, and they want a better class of food.

6596. (*Mr. Kendall.*) Although the miner spends more, yet he requires more, and also a better class of food?—Yes. There is a woman who is living about four or five miles from this place, and she has a husband and four or five boys, who are all working in a mine, and I have made the calculation that they are earning from 11*l.* to 13*l.* or 14*l.* per month, and yet they have not a chair to sit down upon; there is scarcely a cup or a saucer in the place, and as for a bed, what they have got would be a disgrace to the poorest persons in the kingdom. But there are many others the reverse of this.

6597. Do you think that is attributable to intemperate habits?—No; I cannot account for it.

6598. (*Chairman.*) But that, I presume, is not general?—No.

The witness withdrew.

Mr. JAMES RICHARD QUICK examined.

Mr. J. R. Quick.

6599. (*Chairman.*) How long have you been practising in Penzance. Between eight and nine years.

6600. Have you had the charge of any mines as the doctor?—Yes.

6601. Of how many mines have you had charge?—15 or 16 at different times. I should mention that I resided at St. Just between 12 and 13 years, and at Chasewater 4 or 5 years, before I came here.

6602. During that time have you had more or less practice in mines?—Yes.

6603. Are you also surgeon to clubs which are not miners' clubs?—Yes.

6604. You have had considerable experience in this district especially?—Yes; I have.

6605. Should you wish to confine your observations to this district?—Yes.

6606. Have you turned your attention specially to the disease which is called miners' disease?—Not specially, but it has always had a considerable share of attention.

6607. Have you kept any register of the cases?—No; I have not.

6608. Have you made any investigations into the disease by means of *post mortem* examinations?—I have never had an opportunity of making one, there is always such an objection to it amongst the miners or their friends.

6609. I suppose you think it is desirable to make such examinations?—Very so.

6610. How have you arrived at your conclusions as to the nature of the disease; merely from the symptoms?—Yes; assisted by the stethoscope.

6611. Will you have the goodness to describe to the Commission what you consider to be the miners' disease?—Chronic bronchitis, or a thickening of the lining membrane of the air passages.

6612. Does the disease usually end fatally?—Yes.

6613. Does it ever lead to consumption?—No.

6614. You are of opinion that it is quite independent of that?—Yes; it is quite a distinct thing from consumption.

6615. Have you never, in your practice, seen any cases in which it has ended in tubercular consumption?—Not as a consequence.

6616. Do not you examine those who are afflicted by the stethoscope?—Yes.

6617. Have you never discovered in any of those cases that the disease was tubercular consumption?—No.

6618. Have you found any cavities in the lungs?—Not in what is commonly called miners' consumption.

6619. Have you met with many cases of real consumption in this district?—Yes.

6620. Does that disease prevail amongst the agriculturists or amongst the fishermen?—They are all liable to it; we get it in all classes.

6621. Do you find it in any one class more than in any other?—I do not know that it is so. I cannot speak from observation upon that point.

6622. Do the cases of miners' disease prevail to a great extent?—After a certain age a large proportion of miners have it, more or less.

6623. At what age should you say that they were generally affected by it?—After the age of 20 years, seldom before.

6624. You think that there is more of it after the age of 30?—Yes.

6625. When a miner comes to you complaining in that way, what course do you recommend him to take for the purpose of preserving his health?—If he can give up the work we recommend it by all means.

6626. Do you recommend a man not to go down into a mine again?—Yes, if he can avoid doing so.

6627. Are they not sometimes obliged to go?—In many cases they are obliged to do so.

6628. For what reason are they obliged?—For the want of other means of obtaining a living.

6629. Therefore after you have warned them of the consequences of going down into a mine again they are compelled for want of other means of obtaining a livelihood to go down?—Yes; many of them are, but some may be able to obtain their living by taking a small farm, or by some other means on the surface. Some of them after giving up going underground will go to work on the burrows, are exposed to the cold, and consequently do not obtain the benefit that they would if they were engaged in other employments.

6630. In those cases do you ever endeavour, at the mines with which you are connected, to obtain employment for them on the surface?—I sometimes direct the attention of the agents to such cases. When a man has become disabled underground, if they can possibly find a place for him to work in at the surface they do so.

6631. When a man is merely affected slightly and comes to you in the first instance, what do you recommend him to do?—To rest, and use the means

that generally relieve such cases. If an advanced case, to seek other employment.

6632. You do not mean the case of a man who is merely slightly affected?—No; perhaps he would not do so, he might endeavour to get work at a shallower level than he was working at before.

6633. In cases where you have seen the men and warned them that the disease would continue if they went to work below, do you think that if they did not go down the disease would be arrested?—I do, if in an early stage.

6634. You think that the disease would be stopped?—I think it would not progress, perhaps they might not get much better, but they would continue to live many years if they gave up working underground.

6635. Being obliged to go to work underground the disease gets worse, and it ends in the early death of the miner?—In some cases it ends in an early death, but not always. Some miners work on in suffering for many years, which they may do by selecting a well-ventilated place. Some mines are worse than others.

6636. Do you think that there is any difference between the tutwork men and the tribute men in the way in which they are affected?—I cannot speak of any difference. I have not remarked it. I should not know one from the other by his appearance.

6637. When the miners come to you do not you enquire where they have been working, and whether at tutwork or at tribute work?—Not always; if they work underground I think the work is very much the same. They use a mallet in boring.

6638. What, in your opinion, produces the diseases?—The disease is produced by several causes; such as breathing in an atmosphere rendered impure by powder smoke, combustion, dust and exhalations from the ground, climbing, and boring, and changes of temperature in going from cold to hot, and vice versâ.

6639. Do you mean in coming up and going down the mines?—Yes, and as well while working underground; if a man has been working in a very hot place, after a time he comes into a draught to cool himself; that is one of the causes that I think would operate in producing the disease.

6640. Have you been down many of the mines?—No; I was down once only.

6641. Have you not turned your attention particularly to the causes of the disease, and considered what are the best remedies for it?—I have considered both, and have found that, although the disease is not cured, it is often very much relieved by emetics, alteratives, expectorants, and counter irritation.

6642. Do you think that the food which the miners eat at all affects the men, or has anything to do with it?—Yes; many of them live very hardly, and are thereby rendered more susceptible of disease. Those who have health have generally very good health.

6643. Do you think that the kind of labour which they perform requires any better food to sustain them than they get?—In many cases I have no doubt that it does; some of them are in better circumstances than others, and have very tolerable food.

6644. When they are out of work, and suffering from illness, and come into your hands for treatment, what provision is there for them?—I am not aware that there is any, in the mines, if suffering from temporary illness only.

6645. If he is suffering from bronchitis, or from miners' disease, does he receive any assistance then? If completely disabled by disease or infirmity they are generally provided for in the large mines, but always so, in all mines, if disabled by an injury. A great number of them are members of benefit societies, and receive pay from them whenever lawfully disabled.

6646. Otherwise there is no provision, I suppose, but the union for a man who is ill?—I do not know that they have any means provided for them, and unless they have some of their own they must have parish relief.

6647. As a patient, I presume you would think it desirable that a miner should have good food while under treatment?—Yes.

6648. But there is no provision of that kind for them?—If a man meet with an accident he is allowed a certain sum monthly during the time he is disabled, if sick he has weekly pay from his sick club.

6649. (*Mr. Holland.*) I think you stated that you had a large number of men in your charge both as ordinary club patients and as ordinary mine patients?—Yes.

6650. A large proportion of both classes come to you?—Yes.

6651. Is there a much larger proportion of chest disease among the miners than among the other men?—Yes; I have here the 16th annual report of the Polytechnic Society, which contains a paper on this subject from St. Just, and which shows that out of 63 deaths, of males above 10 years of age, 34 were from diseases of the chest, and of these 28 were miners and 6 not.

6652. So that three fourths of the deaths from diseases of the chest were amongst miners exclusive of accidents, one fourth being not miners?—Rather a larger proportion, about 4 to 1.

6653. Is the chest disease among miners chiefly that disease which you recognize as the miners' complaint?—Yes.

6654. But does the result of your own observation correspond with that report?—Yes, I think so; pretty nearly for that district.

6655. Of the chest diseases which you have seen among miners, has a large proportion been that which you recognize as the miners' complaint?—Yes.

6656. Are you certain that that miners' complaint is but rarely true phthisis?—I think it is never so.

6657. (*Mr. Kendall.*) In your opinion, does miners' consumption ever degenerate into the other disease?—No.

6658. You do not think that it predisposes the miners to tubercular disease?—No. If there be a tendency to tubercular disease previously, it might hasten its development.

6659. (*Mr. Holland.*) In practice, are the two diseases easily distinguishable?—Yes.

6660. And they vary very much in their history?—Yes.

6661. Is not spitting of blood a very rare symptom in miners' consumption?—Yes; it is not a very common symptom. We meet with it occasionally.

6662. Does it occur in one case in six?—I cannot say exactly.

6663. Does not spitting of blood occur in a much larger proportion in cases of phthisis?—Yes.

6664. A very much larger proportion?—Yes.

6665. Is not hectic of rare occurrence in miners' consumption?—Yes.

6666. Is diarrhœa a frequent consequence of miners' consumption?—No.

6667. Is it a very rare consequence?—It may occur occasionally; we do not expect it as a regular symptom.

6668. Is there much pain in miners' consumption?—Not generally.

6669. Is there much less pain than in phthisis?—There is less pain, unless there is any complication. I am speaking of the disease itself.

6670. Is pain more frequent in phthisis than in miners' consumption?—Yes.

6671. When the disease is considerably advanced, and the miners can change their employment and work at grass, is there a fair chance then of arresting the progress of the disease?—Yes, or, at least, in retarding it.

6672. When phthisis is far advanced can the disease frequently be arrested?—No.

6673. These are clearly distinguishing marks between the two diseases?—Quite so.

6674. (*Mr. Kendall.*) As I understand your evidence, you are satisfied that the miners' disease and

PENZANCE.
Mr. J. R. Quich.
30 July 1862.

true phthisis are distinct and separate diseases?—Yes.

6675. Are you able to state, from having in your practice attended both agricultural labourers and miners, and from having seen cases of true phthisis and miners' consumption, what is the average duration of the one as compared with the other? Or, in other words, after a man is attacked, is the miners' disease longer in causing a man's death?—Yes; it is generally very much longer; it may last for many years.

6676. Take the average in a given number of cases of true phthisis, and the average in a similar number of cases of miners' disease, what should you say was the duration of life after the first attack?—I am not prepared to answer that question.

6677. Have you come to this conclusion, that the miners' disease is of a much more lingering character than true phthisis?—Yes; decidedly.

6678. You are of opinion, I think, that the miner's life is shorter than that of the agriculturist?—Yes; it is generally so.

6679. Of the two, which do you think is the most careless of life; the miner or the agricultural labourer?—The miner.

6680. Although his life is confessedly shorter, yet he is less careful of it than the agriculturist?—Yes.

6681. What is your opinion with regard to the food of the miner? Do you think that he requires better food than the agriculturist?—Yes.

6682. Do miners live better on the whole than agricultural labourers?—No.

6683. Comparing the wives of the agricultural labourers with the wives of the miners, do you think that the miner's wife is as attentive to her husband's food, and as careful in the management of his domestic affairs as the wife of the agricultural labourer?—Some of them are, but there is a great variety in both classes.

6684. But take them on the average?—I should say, taking them on the average, yes. There are, of course many of them who are not so.

6685. You think that they make a shilling go as far as the wife of the agricultural labourer?—Yes, very many of them do.

6686. (*Mr. St. Aubyn.*) Is the principal part of your practice among miners?—Not at present.

6687. How many mines do you attend at the present time?—I attend at only two mines now. I have attended more until lately.

6688. I think you stated that you had only been once underground?—Only once.

6689. You have not made any *post mortem* examinations?—No.

6690. And you are not acquainted with the operations of a miner underground so far as they affect his health?—I have an idea of it, but not from my own observation. I fancy just what it is.

6691. Have you ever made practical experiments on the condition of the men before going underground, and when they have afterwards come up; such as weighing them, or analysing their blood or their expectoration?—No; nothing of the sort in any way.

6692. (*Mr. Davey.*) I think you stated that the miners were obliged to work in foul air as they cannot get any other place to work in?—I stated that many were obliged to continue their work underground, not in foul air.

6693. Do they not receive better wages when they work in these bad places?—I think they do.

6694. Are you aware whether they work there from choice, and because they do receive better wages?—I suppose they do, and that the extra wages are an inducement.

The witness withdrew.

Adjourned to St. Just at 12 o'clock to-morrow.

ST. JUST.

Thursday, 31st July 1862.

PRESENT:

The Right Honourable Lord KINNAIRD, K.T.	JOHN ST. AUBYN, Esquire, M.P.
NICHOLAS KENDALL, Esquire, M.P.	P. H. HOLLAND, Esquire.

The Right Honourable Lord KINNAIRD, K.T., in the Chair.

Captain RICHARD BOYNS examined.

ST. JUST.
Capt. R. Boyns.
31 July 1862.

6695. (*Chairman.*) Of what mine have you charge?—Huel Owles.

6696. Have you charge of any other mines?—Yes, I have had the management of another mine this last week or two, but I cannot make much report of that yet.

6697. What is the produce of Huel Owles?—Tin.

6698. How many men are employed underground?—About 170.

6699. Is it a long established mine?—The present working has been from 1834. I have been in the mine from that time.

6700. Is it a deep mine?—Not very deep. We have several shafts down from 160 to 170, the deepest shaft would be 175 fathoms; that is the deepest pit in the mine.

6701. How do the men ascend and descend there?—By footways.

6702. And ladders?—Yes.

6703. What is the distance between the staves of the ladders, are they 10 or 12 inches?—Principally a foot; in this last year or two we have introduced some 10-inch distances. The miners do not like the short distances.

6704. Which do you think is best?—I think that the foot is quite as good as the 10 inches.

6705. Are there any hot levels in the mine?—I do not know of any part of our mine but what is in a good state of ventilation.

6706. With regard to the heat, have you ever ascertained the heat of any of the levels?—No; our miners can work with all their clothes on comfortably; in some mines they throw their clothes off, they are not required to do that in our mine, ours is rather a cool temperature; but what the temperature is I am not exactly prepared to say. I think the principal reason of that is because we have cross-cut from one lode to another. We are working on six or eight lodes, and a great many of the parallel lodes are being cross-cut, which is quite as good if not better than bringing down a shaft from the surface.

6707. Are there any particular shafts which you know of that are down-cast or up-cast shafts?—I have observed a current of air coming up and passing down slightly.

6708. Is there constantly the same up and the same down-cast, or do they vary according to the wind and weather?—I think that there is a variation. I have been struck with the current going down and

coming up, but I cannot say that it continues regularly. I do not think it does; I think that it varies.

6709. If it changes, and there is no regular up-cast; does that air circulate constantly through your cross-cuts and your winzes, without coming up at all to the surface; may not that be the case?—I should fancy that it came up. Where we have so many cross-cuts it must get up in some way or other. I can hardly see how it can come up where there are very few shafts in a mine; I think that it would die away.

6710. And circulate through them?—Yes, I think it would.

6711. How far would you say that it would be safe as regards ventilation to drive a level from a winze or a cross-cut?—30 or 40 fathoms in most cases would be quite far enough. Sometimes we can drive 50 fathoms better than we can drive 10 or 15.

6712. You cannot account for that?—I cannot.

6713. Are you speaking now of the same mine?—Yes, in our own mine. On the average we can drive 20 or 30 or 40 fathoms very comfortably.

6714. How do you judge as to being able to drive further or not?—The burning of the candles is one test.

6715. Have you any other test?—We find that we cannot breathe very well when we get into bad air.

6716. You have no test but the burning of the candles or the feelings of the men?—We are governed generally by these.

6717. Do you ever try whether the draught ascends or descends the winze nearest the level; whether the draught is up or down the winze which communicates with the level in which you are working?—I think that it is up in most cases. I am not prepared to answer that question with confidence, but I think that the draught would pass up.

6718. You have not tested it?—No.

6719. (*Mr. Holland.*) You have not particularly observed it?—No.

6720. When you find that the candle goes out, and that the men are suffering, do you use artificial ventilation?—Yes.

6721. But not invariably?—Always when required.

6722. Do you think that it would be desirable to do it as a regular rule?—I think very much can be done by turning the draught, as in the coal mines for instance.

6723. (*Mr. Kendall.*) By sollering?—Yes. There is a winze in our mine now where we have put in woodwork on purpose to stop the draught from going up and to send it on.

6724. (*Mr. Holland.*) That is a temporary stoppage of the winze?—Yes.

6725. (*Chairman.*) Do you soller at the side and bottom, or the top?—In this case it is put in at the top for safety.

6726. Have you found that the soller when put in has created a sufficient current of air to allow the candles to burn, and the men to work without suffering?—Yes, quite. I have scarcely known an instance of a candle going out in our mine for the last 20 years. We are in the habit of sinking so many winzes, and have so many shafts from the surface; I think we have nearly 20 shafts in the mine. We do not know much about bad air; we profess to be in a good state of ventilation, and that is one reason why I am not prepared to answer any difficult question upon the subject. Our ventilation is decidedly good.

6727. (*Mr. St. Aubyn.*) What is the greatest distance in Huel Owles from any close end to a winze or shaft?—I do not think that we have ever driven above 60 fathoms.

6728. But you find that even in close ends 50 fathoms from a winze there is no difficulty in a candle burning?—We are often compelled to bring down a winze, or some other means, before we have driven anything like that distance. We have driven nearly 30 miles of levels, and as much as 50 fathoms without artificial ventilation.

6729. That is an extreme case?—Yes.

6730. Ordinarily speaking in your average working what is the distance?—About 20 or 25 fathoms would be as far as we should think of driving.

6731. And you never find that a candle burns badly at that distance?—We have found that at not more than 10 fathoms, and sometimes when the lift has been put down and the ends only just pitched off, the air very indifferent. When the miners have complained to me that the air has not been good, I have called the attention of the under-ground captains to it, and they have given a similar report that the air has been bad, although such a short distance from a draught. That, however, is a very rare instance.

6732. (*Chairman.*) When were you last down the mine?—I have not been in the habit of going down lately. I have never had much underground work except dialling.

6733. Did your health suffer much from going underground?—I am not prepared to say it did; but the doctor advised me not to go underground, as I have been subject to pleurisy.

6734. The underground captain, I suppose, could speak more to this point?—Yes.

6735. Will you give me the names of your underground captains?—John Halls the senior captain and William Rowe. I have laid out the surface work entirely.

6736. On setting days a list of rules is referred to, is it not?—Yes.

6737. Have you a copy of that list with you?—No.

6738. You can furnish it?—Yes. Our rules are stuck up in three or four places in the mine, constantly, and we refer the miners to them every setting day.

6739. With regard to candles; what do the men pay for the candles?—9*d.* per lb.

6740. And how much for the powder?—The same.

6741. Those are bought wholesale by the mine, I suppose?—Yes.

6742. What is the average price for which you get candles and powder?—Candles, I should think, at about 6*s.*; from 5*s.* to 6*s.* Of powder, 54*s.* or 55*s.* is about the average.

6743. Is there any peculiar kind of powder which you use?—We have been supplied from Kennall Vale I believe from the beginning. We have tried a new sort of powder from Davey, Brothers, and our miners did not like the powder, it did not seem to have sufficient percussion quality. It was too slow in doing its work. The smoke, however, was not quite so much.

6744. Are the men allowed a certain quantity of candles each time they go down?—Two lbs. are delivered on Monday morning for the week.

6745. Are they never allowed any more?—Scarcely ever. A great many applications are made for additional candles, but we hold that all increase of consumption will come out of the adventurers' pocket.

6746. And therefore you limit it?—Yes. In some cases where candles have been stolen, and where men have been working a very long time, we have given more, but very seldom.

6747. What is the amount of money that the men pay for club-money?—One shilling. That includes the doctor and club; sixpence the doctor and sixpence the club.

6748. Is there anything paid to the barber?—No.

6749. I suppose that for sharpening the tools there is so much?—The blacksmith's charge is deducted with the materials. It is very small compared with what it used to be, since cast steel has been introduced into the mines.

6750. Are the tamping rods of iron?—Iron, with a composition of brass, copper, and some mixed metal, but latterly we have introduced oak sticks. We cannot get the men to do as we wish. When the

agents turn their backs, the men will very often charge their hole with the borer; they are very reckless in this respect.

6751.—These tamping rods are of composition?—Yes, a piece about two or three inches long, put on at the bottom of an iron bar.

6752. (*Mr. Holland.*) Is it bronze?— Yes.

6753. (*Chairman.*) And it is such that if struck against the rock it will not create a spark?—I have heard some of the miners say that they have seen fire when they have been using them.

6754. The object, of course, in furnishing them with these rods is to prevent a spark being created and igniting the powder?—That is the object.

6755. But you are not quite sure that the composition which you use has had that effect fully?—I believe it has. I have heard some of the miners say that they have seen fire in the hole. Some of our miners would strike fire with almost anything. We have engaged to supply them free of cost with oak sticks, which is the hardest wood, and the greatest portion of them at this time are supplied, on purpose to prevent accident.

6756. Is the oak stick considered by a miner heavy enough for that work?—That is a question upon which they differ very much. I can come to no decision at all upon it in my own mind. I have heard some of our best miners say that they can sufficiently tamp the powder with oak to blast the rock in this district, and that powder does not require so much tamping as some of our miners imagine, and I believe that that is a very prevalent notion.

6757. But there is an impression that they cannot tamp sufficiently with an oak stick?—That impression exists, but I am inclined to think that the powder can be tamped sufficiently with it.

6758. At all events an oak stick is another tool that they have to carry?—Yes, they would have to carry it down; it would be very little trouble to them to do that.

6759. Would an oak stick be substituted by you for the other tamping rod?—No.

6760. (*Mr. Kendall.*) They would take both?—Yes; the tamping should be put in on the powder with something stronger than an oak stick, I think.

6761. (*Chairman.*) Therefore you would consider the oak stick extra to the present tamping rod?—Yes.

6762. (*Mr. Holland.*) Is the oak stick used for pushing the powder down, and the tamping rod for driving the tamping?—Yes.

6763. (*Chairman.*) Has the safety fuse been introduced in your time or was it before your time?—Since my time; I cannot say how long.

6764. That has been of great use in preventing accident?—Very great; there is no question about that.

6765. Have you had any accidents from blasting in your mine in the last five years?—We had an accident not more than two months since, but it was not a serious one; the man has recovered nicely. The rock was blasted to the bottom of the hole, I believe. The man has gone to work again. We have had accidents in our mine; but not many considering we have been working a long time. From 1834 up to this time, only three men have lost their sight.

6766. Was that what induced you to recommend some other tamping rod; was it in consequence of an accident?—It was in consequence of the accident the other day. We cannot get the men to use the oak sticks. We have offered to supply them with as many as they will call at the carpenter's shop for; when one has got unfit, they can have another for asking, and yet they will not do it.

6767. How did the accident occur to which you have last referred; can you state the exact cause of it?—I think that the man was charging the hole with the borer; he fired the charge.

6768. (*Mr. Holland.*) While tamping?—Yes.

6769. (*Chairman.*) Do you use cartridges?—Scarcely ever.

6770. Only in wet places?—We have no wet places. This district is very free from water; it is a very dry district; and very few cartridges are used; I should think that a dozen would last us six months.

6771. Have you ever in your experience seen a cartridge made by a miner on the spot, and then put into the hole?—Yes.

6772. How are the doctors appointed?—By the adventurers.

6773. Is there any examination or qualification for a doctor to be appointed as a mine doctor?—I cannot say much about that. I think that it is done by interest principally. In some of the mines in the parish the men have the control so far as to make choice of their own doctors, and keep their own club, but this is a bad way of getting on. We find that these things do not last long; they are generally knocked up. Our club is a great benefit.

6774. Is the club money only for visible accidents, or is it applicable for sickness in the mine?—It was started at the commencement as a sick and hurt club, and we found that the expenditure was more than the income; then we had to bring it back to a hurt club, and it is that now; it just meets its demands as near as possible.

6775. Do the men who are blinded receive anything from the hurt club?—Yes; and will as long as the mine is at work I expect; we have not thought of reducing their pay, or cutting it off.

6776. Men who have left work from illness have no right to relief from the mine?—We have occasionally departed from the regular rule, and in particular instances have relieved them. There is a provision in the rule of the club that the full pay will be reduced if the club will not support it, and that they will receive in proportion as the club will afford.

6777. Are the rules of the club given to the men, or do they know them?—They are read to them frequently

6778. Are the rules of the club included in the rules which I have asked you to furnish?—No; they are a separate set of rules, and there are rules of the death club as well.

6779. Have you any objection to furnish those rules?—I shall be very happy to do so.

6780. With regard to payment, do you pay a pair with notes or gold or partly gold and partly notes?—Partly gold and partly notes.

6781. Do you think that the payment of notes may induce the parties to go to the public-house in order to get change?—I suppose so, in a very few cases; but many of the men would go to the public-house whether they got notes or not.

6782. (*Mr. Holland.*) Does the mode of payment induce them to go to the public-house materially?—No; I think not.

6783. You have said that the club money was originally for a sick and hurt club, and is now for a hurt club alone; does it about balance itself now?—Yes; that is, keeping on the hurt money and relief in a few cases of any serious illness or any great destitution where persons are not able to work.

6784. Is not that independent of the club?—We have power by a regulation that we can relieve those cases out of the hurt club.

6785. Then the hurt money is a little more than sufficient to pay for hurts?—Yes.

6786. And the balance is used for extreme cases of sickness?—Yes.

6787. When you drive a level 50 fathoms in advance of a winze, I suppose you have a soller; you cannot drive it without a soller, can you?—Yes, sometimes we can; but very often we carry a soller or bolt at the bottom.

6788. A kind of imperfect soller?—Yes; for instance, if it is a tramroad level in fixing the runners for a tramroad the soller is easily made, and by carrying the level a little higher we can carry a bolt underneath the tram.

6789. You spoke of some of the men saying that

sparks had been seen in working with a tamping tool which was made of mixed metal, do you believe that?—No; I have no confidence in that statement; although we do not know exactly what the metal is. For instance, we knocked up a cylinder which was worn out, it was made of nice soft yellow metal, and that has supplied us for a considerable time.

6790. (*Mr. Kendall.*) But you mix tin with it?—We put a little tin with it occasionally.

6791. Your club money is one shilling a month, of which sixpence goes to the doctor and sixpence to the man?—Yes.

6792. For that the doctor is obliged to attend the miner's family, is he not?—Yes.

6793. You have mentioned about your own mine; from your experience, and from what you have heard, do you think that there is good faith kept with the miners, as far as the club money goes, by the adventurers and the pursers?—Yes; I have no doubt that it is kept correctly; our account has been kept separate from the beginning.

6794. Without speaking of your own case, do you think that good faith is kept with the miners by the adventurers?—I should hope so; in our case it is kept to a farthing.

6795. You have great experience, and I know that you have great shrewdness, and I want an answer to my question, which I am sure you will give me, be it for or be it against the adventurers generally; I ask you fairly, do you believe, as far as you have heard, that good faith is kept by the pursers on behalf of the adventurers with the miners as far as club money goes, or do you think that in some cases profit is made by the adventurers out of it?—I do not know of any case where any profit has been made. I cannot answer that question. Our account has been kept to a farthing, and balanced every quarter.

6796. As far as your experience goes, the money which is usually charged to the miner is not much more than enough to meet hurt cases?—No.

6797. You tried to make it meet hurt and other cases, and it would not do it?—It would not support that.

6798. But now, as I understand you, you first of all make hurt cases a matter of course, and if you have a balance you apply that balance to the other cases?—Yes.

6799. So that the whole of the money is applied to the benefit of the miners in some way?—Yes; every farthing in our mine, and I shall be very glad to see it again fully established as a sick and hurt club, which we shall do on the first opportunity, and then if we have not the means to support that we shall be obliged to fall back on the hurt club again.

6800. In Huel Owles your working extends back to 1834, but was not Huel Owles worked long before 1834?—Yes; I know that my grandfather worked Huel Owles for some considerable time.

6801. When you began to work in Huel Owles there were considerable old workings?—Yes, very extensive old workings.

6802. And you resumed a great portion of those extensive old workings?—We did. The sea level was brought in from high water about three quarters of a mile. We have driven that sea level into all the tenements round there.

6803. From 1834 up to the present time, after making use of the old workings by cross cutting and so on, you have found the natural ventilation very good?—Very good indeed.

6804. And you have never known a case where a candle has gone out?—I have scarcely known a case.

6805. Do you not think that sometimes in this county there is false economy in not having cross cuts?—Yes, I am quite satisfied in my own mind that it is very bad mining indeed when cross cutting is neglected. With good ventilation the men can do 50 per cent. better labour.

6806. The non-use of cross cuts is a very false economy?—I think so.

6807. You stated that you have observed that there is a variation sometimes in currents, but those variations are not very capricious are they; they do not change every hour or two?—No; but generally these currents seem to me to be so very trifling that you can hardly detect whether the current is up or down; it is very slight so far as is detected from the surface.

6808. Can you tell from the nature of the current whether or not the foul air is (to use a mining phrase) wabbling about the different levels?—No.

6809. You think that it moves about?—Yes.

6810. It remains there you think?—No; I think that it will pass up the mine eventually; but then it moves about through the mine before it finds its way out. It cannot get up at once, that is very clear.

6811. It takes some little while to get up?—Yes. Where there is so much good air getting into a mine, the poor air must be driven away.

6812. You have very little water in your mine you say; if that be the case, if there be dust in any mine, you ought to have dust in your mine in working; did you ever hear the miners complain of the dust?—No; we have sufficient water to prevent dust.

6813. Did you ever hear in your life a miner complain of dust?—Never.

6814. Of swallowing dust from boring and so on?—Never. There is a dampness, but the water in the district is certainly very little.

6815. Generally speaking, are the miners healthy as a body or not?—Yes. I am prepared to say that our men are a very healthy lot of men.

6816. (*Chairman.*) You are speaking of your own mine?—Yes. I would rather make remarks upon our own mine than upon any other. I know very well that from the meat which our men carry down with them there cannot be much amiss with them.

6817. (*Mr. Kendall.*) Do your miners live better than agriculturists; do they spend more money on their meat?—Yes, I think that that is certain.

6818. What is the nature of their food; pasties?—No, they do not do much in pasties. They carry underground bread and butter, and a little light cake, but I think that most of them live pretty well at home.

6819. What do they have for supper when they get back; is not their evening meal their chief meal?—Yes; they get beef sometimes and pork steaks, and so on; they can manage to live very well.

6820. Taking them as a body they are very intelligent I know. Are they reckless in their mode of dealing with powder, and so on?—I think very much so; some of the oldest men in our mine are so. There is one man in particular now, a man with eight or ten children, a nice steady man as any in the parish, and yet the miners and the agents tell me that when he charges his hole, he will take up the first tool that comes to hand, whether it is a borer or a bar, and will knock away upon the powder with the full length of the arm, the same as if it had been a little soller. That is only one instance, but as a rule the recklessness is principally among the young men.

6821. But you mention this as a case which has grown up with the man's growth?—Yes.

6822. They are reckless about powder?—I think so. I think that if anything could be done to make them a little more careful in that respect it would be very desirable.

6823. (*Mr. St. Aubyn.*) To the best of your knowledge and belief have the adventurers of the mines ever derived a single penny of profit from the club money belonging to the mines?—I do not know of any instance where they have done so.

6824. To the best of your belief they have not?—I have heard some observations upon that question before; but I have never known a case where money deposited by the men has been put to the adventurer's account.

6825. You have read observations to the contrary.

St. Just
Capt. R. Boyns.
31 July 1862.

Do you believe those observations to have had any foundation in truth ?—I do not know that I have got anything in my own mind definite upon the subject. I have heard a talk upon the subject, and I know very well that it ought not to have been so if it has been ; not a single case has ever come under my own observation.

6826. With regard to the accidents from tamping, we know that the men are very reckless ; do you think it would be possible by any means which you could devise to prevent the men using their borers and bars in tamping ?—I fear not ; I do not see how an accident could happen in charging with an oak stick ; but if the hole should miss fire the miner would beat out htat hole again, and although it need not be done of necessity.

6827. You mentioned cases in which the men had oak sticks supplied to them, but that they would prefer an iron bar ?—Yes ; the ordinary tamping bar.

6828. You do not think that it is possible by any system of watching to prevent their using an iron bar ?—I do not think it is. After an accident they will come to their senses a bit and will use oak sticks, but they get a dislike to them in a little while.

6829. Supposing a rule was made that when a hole had missed fire in no instance should it be re-opened without the presence of the captain of the mine, and that a fine should be imposed if that rule was broken ; do you think that that could be carried into operation ? —No ; I think that even then they would risk the penalty of a fine.

6830. You think that they would open the hole again ?—I think they would. In the coal mines, for instance, a coal miner is not allowed to fire a hole unless one of the under-captains is present ; but the men manage to do it ; they are fined or brought before the magistrates if they do so.

6831. Where do you get the composition which you have attempted to introduce for tamping the hole ?— We have been supplied for years from an old cylinder, from one of our drawing engines which we threw out for a new one; it was very good metal.

6832. What was it made of ?—Brass ; very nice soft metal, very good metal.

6833. Yellow metal ?—Yes ; we have put a little tin with it occasionally, but the old cylinder as it was was very good metal.

6834. Have you had it analysed to know exactly what its component parts are ?—No.

6835. You cannot be perfectly certain without its being analysed whether it may not contain some particles of a composition which may strike a light ? —No, I am not prepared to speak positively, but I should not think that there was any iron in it. I dare say that it is made of good metal.

6836. But your opinion is only founded upon the appearance of it. You cannot say for certain that there is no iron in it ?—No.

6837. Then you have no guarantee that it is a perfectly innocuous metal to use for that purpose ? —No.

6838. (*Chairman.*) Is a man-engine introduced at all into this district ?—There is one in Levant.

6839. Has it answered there ? — Yes ; I should think that it answers pretty well in Levant, it being a deep mine, it is an accommodation to the miners ; but they must be very careful I think, in my opinion quite as careful as in coming up by ladders.

6840. Have you heard of any accidents there from the use of it ?—Yes ; two or three, and perhaps there may have been more ; I know that one of the agents lost his life in coming up some year or two ago.

6841. From missing his step ?—I do not know the particulars. I think that in stepping from the man-engine on to the platform he missed his step in some way ; he got crushed between the engine and the platform, and lost his life.

6842. Have you any personal experience of the man-engine ; has it been introduced into any mine with which you are connected ?—No.

6843. Has a skip been introduced ? — Only for drawing stuff, not for taking the men up and down. In Botallack it is used, I think, for that purpose. I do not think favourably of it myself.

6844. Have you ever used it yourself ?—No.

6845. You cannot speak of it from your own experience ?—No ; but I do not think that it is a proper way for men to go up and down, and especially if working with chain.

6846. Why not ?—I think that a chain may break at any moment.

6847. Supposing you were to hear that a skip had been in operation in a mine for the last 30 years, and that it had carried some hundreds of men up and down shafts, or pits, without a single accident ever having happened, would your opinion be altered as to the danger ?—Not at all ; I should still have the same opinion that it was not a safe transit.

6848. Are you talking of a one-link chain ?—Yes. If it had worked 100 years and had had no breakage, I would not trust myself a bit the sooner on that account. We have had a skip drawing stuff for several years, and have had scarcely any breakage.

6849. That is a single link chain ?—Yes.

6850. Supposing a chain was made of three links instead of one, should you then think it safe ?—No ; I have no confidence in iron to draw up men.

6851. But if it went on for 30 years drawing hundreds of men without any accident, and if you would not consider that a proof of safety, what in your opinion would establish the safety of any means of bringing up men ?—A man-engine.

6852. What would prove it to you to be safe ?—I should object to chain, because a crystallization goes on in iron, so that it may give way at any time. If working for 30 years without a breakage, the chain would have to be thrown out repeatedly in that time, I would not, therefore, trust my life to a chain. I think that after the footway, the man-engine is the thing.

6853. What do you think of a wire rope ?—I think that it is very much better than a chain.

6154. Would you think a skip safe with a wire rope ?—No ; because they are very liable to go off the road or trip. I do not think there is any safety in a skip as a transit for men. I am now speaking not of perpendicular shafts, but of underlying shafts. With a good rope and with perpendicular shafts, as in the coal mines, I think that that is quite as safe a way of conveying the men up and down as with a man-engine, and even more so because there is no changing. A man must have his wits about him with a man-engine to change every 10 or 12 feet. In a perpendicular shaft, I think that a skip would answer with a rope, but not with a chain. I would never go down in a mine with chain unless it was perpendicular, if there were a ladder road.

6855. You have been at Huel Owles since 1834. I think you said that three men had lost their eyes from blasting ; have any men lost their lives from blasting? —No ; I do not know of a single case.

6856. Have any lost their lives from stones falling or from the country coming away on them ?—Yes ; we have had a few accidents in that way, I think that two or three men may have lost their lives, but not more than that.

6857. Have any accidents occurred from the men falling off the ladders ?—Scarcely an instance. Our footways are kept in good condition. I have strictly urged this upon our agents.

6858. You are acquainted of course more or less with all the men who work in your mine ?—Yes.

6859. Of what age are they now, are they young men or old ?—The majority of them would be young men.

6860. Under 30 ?—Yes a return of that has been sent in from our mine.

6861. Do you find the men leave off work at an early age with you, and that they are obliged to retire at an early age from illness or other causes ?—No ; I have stated that I think that the men are very healthy indeed, and my reason for saying so is that they can

generally clear their allowance ; and can work good long hours.

6862. Are there many men in your mine who are affected with what is called miners' complaint, is it prevalent with you ?—Hardly a man, owing mainly to the state of our ventilation. There are some mines in the parish which are hot ; Levant and Botallack have been so.

6863. Your's is not a wet mine ?—No ; still we have pretty much water in different parts of the mine ; there is not a wet mine in the district.

6864. The men work to a good age with you ?—Yes, if they take care of powder and shot.

6865. And the mine is well ventilated ?—Yes.

6866. Are the men well provided for in respect of dries ?—Not very ; I have an objection to dries in a mine, and my uncle had before me. We are working in several parts, or over a large surface, and it is desirable that the men should change as near where they go down as possible, we have several changing houses ; but even if they had all to go down at one place, I should like to have different changing houses. There is nothing that I should dislike more than to have the whole of the Huel Owles men in one changing house. I think strikes and other evils may to a great extent be traced to this source.

6867. In the different changing houses which you have, is the accommodation for the men good ?—We have put up a dry in the last three or four months for 60 or 70 men ; they change in the boiler-house in some instances.

6868. Do you approve of that ?—No ; and yet it is a nice place for drying their clothes. The powder is kept outside under sheds. I do not think that the boiler-house is the place for the men to change.

6869. Have you it in contemplation to erect more changing houses in different parts of the ground ?—Yes ; but they will be small ones. The dry which we have put up is very good indeed for 60 or 70 men. We have a warm-water place where they can wash under cover. My principal objection to having one dry is, that it would get the men all together, which I should like to avoid as much as possible. We have 170 men underground and 36 boys ; in the whole, we have 245 men, 138 boys, and 66 girls, making 449.

6870. You say that you prefer separate changing houses, and that those separate changing houses should be near the footways ?—Yes.

6871. Have you ever thought whether it would be desirable to have a portable iron or wooden changing house which could be moved to the different footways ?—No ; we can put up a changing house at a little expense.

6872. What is the cost of putting up a changing house for 60 men ?—I have not gone accurately into the cost ; still I think 100*l.* would cover the entire expense.

6873. You talk about changing in the boiler-house. I suppose you think that that is dangerous to a certain extent in case of an explosion of the boiler ?—Yes ; and because the men will take often their powder with them.

6874. Is the water here injurious or not for the boiler ?—Our water is pretty good.

6875. You never had a boiler explosion ?—No ; but I think that better attention ought to be paid to the cleansing of boilers. We keep a memorandum of of it in our mine, and we work by rule in that respect.

6876. How often do you think that a boiler should be cleansed out ?—I think that it ought to be cleansed every four months ; it depends upon the condition of the water ; there is a little trouble in it, but a great deal of safety. I think the cleansing should be attended to regularly, to see that the thing is all right, and how the water is acting on the iron. We keep a regular entry of the cleansing of every engine in the mine ; we have seven working. I make our engineer keep an account of this, so that I may refer to it at any time.

6877. Do you think that that is generally done ?—No, I think not. It is my opinion that the time of the boiler being cleansed should be recorded in the counting house. Engineers are inclined to shrink from it, as it is hot trying work ; but it is work that should never be neglected.

6878. (*Mr. Holland.*) Is once in four months enough for safety when the water is impure ; do you know of any case where the water is so bad and so full of sediment as to require its being done oftener than once in four months ?—I know that there would be a thin cab inside the boiler in four months ; and if so, the sooner it is removed the better, both for safety and economy. There is a great deal of saving and a great deal of safety in this I verily believe that in the average of mines the time is twelve months instead of four. A great many men will, what they call, blow out the boiler, but there is no safety in that.

6879. (*Chairman.*) Have your boilers a water gauge so as to show what quantity of water is in the boiler ?—Yes.

6880. Is that general ?—I think so.

6881. Is the balance of your club money taken every year ?—It is balanced every three months ; we have a separate club account book.

6882. You stated that you did not know a case in your mine where the candle had gone out on account of the condition of the air ?—Scarcely a case.

6883. Is it reported to you by the captains when the air is bad ?—Yes. The captains in our mine keep a daily report of every place which they inspect. That is not general. Some agents have to send their reports to London ; our agents have to enter them in the report book.

6884. And it has never been reported to you that there has been an end so bad that the candle would not burn ?—I have scarcely known a case of the sort.

6885. (*Mr. Kendall.*) With regard to the tamping, suppose that you made a regulation that in no instance should any man when a hole has missed fire attempt to re-open that hole under a severe fine, notwithstanding that he would lose a great deal of labour, and the position of the hole and the value of the position; do you think that you could carry that out by fine and by order ?—I think not. I think that if the fine was to the extent of their month's getting they would carry out the same hole rather than put in another.

6886. (*Chairman.*) Would it be desirable to have it reported to the captain when a hole had missed fire ?—I think that the captains like to keep out of the way as far as they can.

6887. To what extent have you been working since 1834 ?—We are at this time driving 43 levels, by small pairs of men, in different directions in the mine. Our mine has been opened in levels and shafts nearly 30 miles. I think that that is more than any mine in Cornwall has done. In the last seven years we have been opening in our shafts and levels nearly a mile and a quarter a year.

6888. (*Mr. Holland.*) Actual driving ?—Yes ; and I think there are but few instances where a mine is being explored on a more extensive scale.

The witness withdrew.

Captain Thomas Trahair examined.

6889. (*Chairman.*) What is the name of your mine ?—Balleswidden.

6890. Have you the charge of any other mine ?—No.

6891. How many men do you employ underground ?—Over 200.

6892. On the surface how many have you ?—We have 450 altogether, I think ; that is, men, boys, and girls.

St. Just.

Capt. T. Trahair.

31 July 1862.

6893. What is the youngest age at which the children work above ground?—Varying from 8 to 12 years of age.

6894. At what age do they go below ground?—We calculate at 14 years of age; from 12 to 14.

6895. Do you not allow them to go underground below that age?—No; no boys should go underground before he is 14 years of age.

6896. What is the greatest depth of level in your mine?—150 fathoms is our deepest level.

6897. What mode have you for the men to go up and down?—Some of our men go up and down in a skip and others a foot way, what we call the ladder.

6898. I believe that you have lately introduced the skip?—Yes, it has been working a year and a half or two years.

6899. Do the men object to use the skip?—They would like to go up and down in the skip very much oftener if we allowed them.

6900. Why do you not allow them?—We cannot allow them to go up and down and discharge, our work time will not allow it.

6901. Is it a single skip?—It is a double skip, and we can discharge plenty of work too.

6902. What regulation do you make with regard to men going down; is it at certain hours?—Yes, seven and two.

6903. I suppose that the tut-work men go down more than the tribute men?—It is more especially for the aged men; we let the young ones walk.

6904. Do you think that men having that means of going down can work below at a greater age?—Yes, certainly, it is a great benefit to the men.

6905. Do you think that it is a benefit for you to employ old and experienced men in working?—Certainly.

6906. Then the means of ascending and descending enables you to have more experienced men?—Yes, it does; and not only that, but we can get more labour out of every man by his riding up and down. We perhaps calculate two or three holes for a man to bore in a day. I think it is better for a man to ride up and down by the skip, and it will not harm him so much as if he put in an extra hole every day of his life. A man's walking fast in the footways is very injurious.

6907. How long does it take him to come up the ladder?—It ought to take from three quarters of an hour to an hour, but some of them come up in twenty-five minutes.

6908. You think that they injure themselves by coming up quickly?—Yes, just as much by walking fast in the footways as in damp ends. Very often when they are out the young men walk together, and one will not give way to another.

6909. I suppose you have no case in point of a man being injured where you can quite trace it to that cause?—No.

6910. How do you fill the skips?—We let our skip go just to the level of the soller; the top of the skip should come to the level of the filling soller, so that a man shall not heave at all, but only do it at the side.

6911. Have you a hopper?—No, I never saw one; our lode is very soft stuff, and you would be obliged to dig it out of the hopper again; we tip it into the skip.

6912. Would it not save time if you had a hopper that would, immediately on the skip arriving at the level, fill the skip?—I cannot see that it would; our lode is just like mortar, after our skip is up we dig it out with a pick; I cannot see that it would be any advantage to have a hopper.

6913. If any means could be adopted so as to fill the hopper quickly, it would give you more time, would it not?—Just so.

6914. And it would enable you to take more men up and down?—Yes.

6915. Do the men ever object to go down in the skip?—Never.

6916. Before it was introduced, did you ever hear that the men were likely to object to it?—I never saw any one ride in it before we put in one. All the agents go up and down in it, and we can get from the 140 in two minutes.

6917. How many men go up at a time in the skip?—Two.

6918. Have you two skips at work?—Yes, one going up, and the other going down.

6919. How is the skip hauled up, by a chain or a wire rope?—It is hauled up by a hempen rope, and at the end of that we have a double $\frac{5}{8}$ths chain; our hempen rope will heave up 30 tons.

6920. Have yon ever tried a wire rope?—No; but I have seen them at work.

6921. Do you see any objection to them?—They may be equally safe, as far as I know; and if they are as safe I also think that there would be a saving on the wire rope. You have not that amount of weight to heave.

6922. Therefore a wire rope would be a cheaper means of hauling up the skip than either a chain or a hempen rope?—Yes, certainly; you must do the one by steam, and it costs more to do it.

6923. Can you state to the Commissioners about the cost of the skip, and the apparatus?—A skip would cost about 20*l.* with catches to it, that is a patent skip; I can let you know.

6924. Have you ever seen a man-engine?—Yes.

6925. Have you ever gone down a mine in one?—never.

6926. How many men have you employed at your mine?—Over 200.

6927. Have you any close ends in the mine?—I do not know that we have one in the mine; we have plenty of shafts in the mine, something like 20 working shafts.

6928. Have you never been informed that there were ends in which a candle would not burn?—No; if there was any end of that kind I should see it myself.

6929. Do you employ no artificial means of ventilation?—No.

6930. How long is the powder smoke in clearing away from an end after the explosion takes place?—In seven ends out of ten, I think it is not more than five minutes clearing away.

6931. Will you be good enough to explain your plan of ventilation?—Yes (*explaining the same on paper*).

6932. (*Mr. Holland.*) Is the skip shaft vertical to the bottom?—Yes.

6933. Your mode of ventilation is to bring air from the shaft as near to an end as possible by a winze?—Yes.

6934. You do not try to drive it down a winze?—No, the object is to bring it up in this way (*explaining the same*).

6935. There is no one particular shaft which is always an up-cast shaft?—No; the draught is constantly going up the skip shaft, it does not go down; we have two or three shafts in those lodes.

6936. Do all your shafts go down to the lowest level; or how many of them do?—We have no less than two shafts in each lode going to our deepest level.

6937. Going to the lowest level of the lode?—Yes.

6938. To what distance have you ever driven from the skip shaft, before you had a winze?—50 fathoms.

6939. (*Mr. Kendall.*) How have you felt or how have the men felt at the 35th fathom?—The air is not quite so good there; we have no powder granite, or decomposed granite, it is there soft granite, and it is worked with a pick.

6940. Do you find that the air will percolate through the decomposed granite?—Yes; there is no blasting on this lode.

6941. Could the men work for eight hours at the 35th fathom before they hole?—Yes; I never saw it at any other; we have not been accustomed to go as far as that, but we might have done so.

6942. How far have you ever driven ?—From 30 to 35 fathoms.

6943. Have you known cases in which the men have been able to drive 35 fathoms without any inconvenience, before they have communicated with a winze ?—Yes.

6944. Would the candles burn well ?—Yes, just as well as in this room.

6945. (*Mr. St. Aubyn.*) What is the height of your level ?—It is seven feet high.

6946. What is the width of it ?—Four feet.

6947. (*Chairman.*) It is more safe to drive, is it not ?—Yes, the place is ventilated better.

6948. For the actual working is it desirable to give the men plenty of room ?—Yes ; we take away all the dirt.

6949. You have rules with regard to setting the work ; have you copies of those rules stuck up ?—Yes.

6950. Will you be so kind as to furnish the Commission with a copy of those rules ?—I will to-morrow.

6951. What do the men pay you for candles ?—9*d.* per pound.

6952. How much do they pay for powder ?—9*d.* per pound.

6953. Do you use any particular kind of powder ?—No, it is the common powder.

6954. Is there a specified quantity of candles allowed to the men ?—The quantity allowed is 2lbs. per man per week.

6955. There is a deduction made from the men for what is called club money ; will you state what that is ?—To the dead club each man pays one 1*s.* for burial. If a man dies or is killed in the mine each one contributes 1*s.*

6956. Is that only if the man is killed in the mine ?—If a man has died they must pay into that club.

6957. Is there any club fund for injuries ?—Yes ; there is a sick club to which they contribute 6*d.*

6958. Is that only for visible injuries ?—Yes ; not for sickness.

6959. How much is paid for the doctor ?—9*d.*

6960. Does the doctor attend the family of the miner or only the miner, or only the miner himself ?—He attends to the whole family.

6961. How are the doctors appointed ?—Our docter is appointed by the men, not by the adventurers.

6962. How is the election of the doctor made by the men ?—They call a meeting, and decide the matter by a show of hands.

6963. Do you think that the men are more satisfied with the medical men as they are selected by themselves ?—Yes ; there is no question about it.

6964. Is there no provision made for a man when he is unemployed on account of sickness ?—None whatever,

6965. Is there any account kept of the club money ?—Yes.

6966. How often is it balanced ?—Our account is balanced every month.

6967. Do the men know how it stands ?—They can know every month if they like to ask for it, they can come to see ; sometimes it will pay and sometimes it will not, and the purser advances the money if it will not pay.

6968. I suppose when it will not pay, it is because you have had more than the usual number of accidents ?— Yes ; there are more sometimes than at others, and then it will not pay. If we get a little stock of money in hand, instead of giving them 15*s.* or 20*s.* a month, the injured men, we give them 25*s.* a month, so as to take off all the surplus money.

6969. You do not take into account the whole amount for a year, but you ascertain what the balance is every month ?— Yes ; we bring up the accounts every month.

6970. If there is a large balance at the end of a month, you increase the allowance ?—Yes, that is our mode of dealing with it.

6971. If the balance was found to be smaller at the end of another month, would you diminish the allowance ?—No.

6972. (*Mr. Kendall.*) There is a certain sum fixed which the men are sure to receive ?—Yes.

6973. And if there is a balance in favour of the club, you increase the allowance ?—Yes.

6974. (*Chairman.*) And suppose the balance becomes smaller, you take off the additional allowance ?—Yes.

6975. But you do not reduce the allowance below a fixed sum ?—No.

6976. So that there never can be a larger accumulation ?—No. It is considered that it is their money, and that they ought to have it.

6977. Is that same system which you have described adopted in other mines ?—I cannot say that it is.

6978. (*Mr. Kendall.*) Have you known of clubs and witnessed the mode of conducting them in other mines ?—Yes.

6979. To the best of your knowledge and belief is or is not good faith observed towards the working miners by the adventurers and by the pursers ?—Generally so.

6980. Have you never heard of a case in which good faith has not been observed ?—No.

6981. Are you acquainted with the system which is pursued with regard to clubs in other mines ?—No, I am not. I do not know that they work them in the same way that we do.

6982. (*Mr. St. Aubyn.*) You can only speak with regard to the mine with which you are connected ?—Yes.

6983. (*Mr. Kendall.*) But you have worked in many other mines, have you not ?—Yes, in several.

6984. Where there have been clubs ?—Yes.

6985. (*Chairman.*) But you cannot state how those clubs are managed ?—No, I cannot. I rather think that there is a fixed sum. I do not think that they are on a sliding scale.

6986. (*Mr. Kendall.*) In any mine in which you have ever worked, have you ever heard any complaint made by the miners against the adventurers or the pursers as to their being unfairly dealt with with respect to the club money ?—No ; I do not think that the pursers ought to have anything to do with it. It is left entirely in our hands as agents, and the pursers have no more to do with our club than you have.

6987. Have the pursers anything to do with the club money in other mines ?—I believe that they have.

6988. But, to the best of your own knowledge and belief, the club money has never been made use of for any other purposes than for the men ?—Not that I know of ; at all events I am quite certain that it has not been in our mine. I cannot speak for others.

6989. (*Chairman.*) What is deducted in the bill for the barber ?—We have none in our mine.

6990. Do you pay the men in notes or in cash ?—Some of the money is in notes and some in gold ; about 300*l.* in notes, about 500*l.* in gold, and from 300*l.* to 400*l.* in silver.

6991. Do you suppose that the paying the men in notes induces them to go to a public house for the purpose of obtaining change ?—No ; I think that it makes very little difference.

6992. How many boilers have you ?—We have two boilers to each engine, to what I call our draught engines.

6993. How many have you altogether ?—We have seven machines.

6994. Are there 14 boilers ?—No, not 14 boilers ; to the pumping engines we have two, and to the winding engines we have but one.

6995. How often do you have the boilers cleaned out ?—Sometimes once in six months ; some of them will require to be cleansed three times as often as the others, some may require to be cleansed once in

St. Just.
Capt. T. Trahair.
31 July 1862.

four months, while others will work very comfortably for 12 months.

6996. But how do you judge of that?—We judge of it in this way; we find that there is a foulness in the boilers by the bottom cock, but there cannot be anything amiss if the boilers are cleansed often.

6997. You think that that is desirable?—Quite so.

6998. Is there any dust in your mine caused by the men working with the pick?—No, very little; we have a little too much water to have much dust.

6999. (*Mr. Holland.*) In Lancashire there is an arrangement by which the steam boilers are inspected by engineers appointed for the purpose; do you think that it would be wise to introduce that system into this county?—We have paid engineers who come into our mine every week, and never miss.

7000. Do the engineers examine every boiler, its gauge cocks and valves, in order to ascertain that it is safe?—Our engineers inspect our engines every week. They are paid every month in the mine as much as any agent there.

7001. Referring to the skip, it of course saves the men a great deal of fatigue to be carried up and down the mine in the skip?—Yes.

7002. Cannot the men do more work in the course of a day than they did in consequence of it?—Yes; no question about it.

7003. Can you make any estimate of the value of that extra work so performed by the men?—No.

7004. Do you think it is considerably greater than the cost of so lifting the men?—Yes; the cost of so lifting the men is very little.

7005. But the value of the labour saved is very great?—Yes; more than the cost of lifting them.

7006. Would it not be good policy to increase the number of men you carry up and down at once?—We have talked of putting in four bars for the purpose of carrying more men at once, a skip is five feet long, and we calculate upon putting four bars 12 feet long to run in pairs with sets, so that we could take up 6 or 8 at a time instead of 2, and then the skip would act as a means of safety over the men's heads if anything should come away.

7007. There would be a sort of bonnet over the men's heads?—Yes.

7008. Which they have not got now?—No. We could easily put a cover on the skip.

7009. And you think there ought to be one?—Yes; but there is not on ours, and I never saw a cover on one yet.

7010. (*Mr. Kendall.*) Have any accidents occurred since you have been at Balliswidden?—Yes; perhaps four or five, or six.

7011. Of what kind were those accidents?—Generally speaking they were accidents which arose from tamping the holes, from charging them.

7012. Do not those accidents principally arise from the recklessness of the men themselves?—Yes, they do, in 9 cases out of 10.

7013. Is it or not your opinion that as a body the miners are reckless of life?—It is my opinion, and I am sorry to say it; I can give the Commissioners one instance. It is but two months since that a man got down five fathoms under the surface; his candle was out, and he was simple enough to attempt to take off a light from a man's hat who was coming up in one of these men's skips, and which was travelling at the rate of 140 yards a minute, and before he touched the man's head his arm was gone.

7014. Taking them as a body you consider them thoughtless?—Yes.

7015. With regard to the general health of the men in your mine is that very good?—Yes; the health of 7 out of 10 of our men is just as perfect as if they were working in this room.

7016. And that I presume is entirely owing to good ventilation?—Yes.

7017. You have frequent cross-cuts in the mine?—Yes.

7018. Do you find that the men will frequently rush sooner than they ought to do into the ends which they have blasted, or do you not blast much?—Not so much as we do in other parts of the mine.

7019. But where you do blast are the men very reckless?—Yes. After a hole has exploded they run in, as they are anxious to see what amount of ground has been broken.

7020. Is it your opinion that much of the illness from which the miners suffer arises from that?—Yes; I should think a good deal of it. It must affect them.

7021. From your experience amongst miners and their mode of proceeding, do you not think that a great deal of their illness arises from want of care?—A very great deal of it. I certainly do think so, and I am candid about it.

7022. What kind of dwellings have they in this neighbourhood; do they sleep too many in a room?—I do not think so. Their houses are small enough, but they are very clean and very wholesome. I think they live in just as wholesome a house as you will find in the county.

7023. Is Balliswidden a dry mine?—Yes; we generally get all our water at the bottom level.

7024. Do you work a good deal in the dry?—Our tributors are generally working in the dry.

7025. Do you find that there is much dust in your mine?—No; there is rather too much water for that.

7026. Do you never hear men complaining of the dust that is made in boring holes?—Never.

7027. Have you worked up to your present position from that of a common miner originally?—Yes; I have worked underground for 30 years from the age of fourteen.

7028. But have you worked your way up to your present position from beginning as a common miner?—Yes; I have done nothing else. I was only at home six months with fever.

7029. What age are you now?—44.

7030. How often do you go underground at the present time?—Three or four times a week.

7031. How deep do you go down?—I go down to the 140, which is the deepest level, although the mine is 150.

7032. How long have you been agent?—16 years last June.

7033. How long did you work underground as a miner?—I worked for 14 years underground as a miner.

7034. Do you often meet with stronger men than you are?—No; I do not think I do.

7035. Are you in full health and strength now?—Yes; I am just as able a man as I ever was.

7036. When you were working as a miner, did you take your night cores as well as the day?—Yes.

7037. Did you work eight hours a day?—Yes, and very often 12 hours a day.

7038. Was your father a miner?—No.

7039. (*Mr. St. Aubyn.*) I believe your mine was lighted by gas?—Yes.

7040. For how long was it so lighted?—For nine months; from six to nine.

7041. How deep did you carry down the gas?—To the 130.

7042. Was the mine well lighted?—Very well lighted.

7043. Why was that mode of lighting the mine discontinued?—Because it was very badly managed, they threw away a fortune; that is the party who started it; but it ought to have been in existence now in two-thirds of the mines in the county.

7044. The supply of gas, I believe, was in the hands of a company?—Yes.

7045. The adventurers had nothing to do with it except to pay for the gas which they consumed?—No.

7046. Under proper management do you think that

the gas would have paid?—Yes; and very much better than candles, I think; there is no question about it.

7047. Did you ever hear or observe that the use of gas had any deleterious effect upon the air?—No.

7048. Did you ever hear the men complain of it?—The men complained when the gas engineer did not attend to their work, and they found an escape of gas from a fracture; it was complained of then.

7049. But not before then?—No.

7050. That was because the tubes were not of a proper description, was it not?—Of course, the tubes got out of order in time.

7051. Do you think that there is anything in the nature of a mine, or in using gas in mines, which should prevent its being used with proper management?—I think that gas is as well to work by as candles. I would as soon work with it to-morrow. I never viewed a pitch with a candle so well as I did with gas.

7052. The adventurers paid a certain sum for the use of the gas?—Yes.

7053. Was it as economical to them as the use of candles?—Yes.

7054. Did the adventurers charge the men anything for the light?—Yes.

7055. The same sum as for candles?—No, not so much by a sixth part. Of course the candles would cost them 1*s.* 6*d.* a week—2 lbs. a week at 9*d.* a pound, and for the gas we charge them 1*s.* 3*d.* instead of 1*s.* 6*d.*

7056. (*Mr. Holland.*) Had they a much better light?—Yes.

7057. (*Mr. St. Aubyn.*) What did you pay per cubic foot for the gas?—Before they commenced to supply it we were to give them so much a year for the whole mine; I cannot tell you what.

7058. You made a contract with them?—Yes; we made a contract that they should light the mine with gas, and that we should pay so much a year after they had lighted up all the mine, but that was never done.

7059. Were the charges that you made upon the men sufficient to provide the amount that you had to pay to the company?—Yes.

7060. So that you lost nothing by it?—Of course we never did.

7061. The result of your experience with regard to gas is that if the company managed it properly it would answer to introduce gas into the greater part of the mines in this country?—Yes; if the mines were well ventilated.

7062. And further that it would be both economical to the adventurers and to the men?—Yes.

7063. Without any detriment to the air, or to their health, if it were properly managed?—There would be no detriment whatever.

7064. (*Mr. Holland.*) Do you know how many jets they use?—I cannot say.

7065. (*Chairman.*) You have stated that the illness of the men was very much caused by their own want of care; what is the illness to which miners are liable from want of care?—In the first place, I fancy that they should be a little more careful in going up and down the mine by their footways. I mean that they force themselves to an extent that they have no right to do. I fancy that it produces shortness of breath in a certain time.

7066. Can you give any other example of want of care on the part of the miners?—There is of course the rushing into the powder smoke.

7067. Is there any other cause which, in your opinion, produces illness arising from want of care?—I do not know anything more.

7068. Do you think that the illness of the men is ever produced by bad air or poor air?—Yes, I believe it is in some mines.

7069. Would any care on the part of the men prevent them suffering from that?—Not if they went into bad air.

7070. The only way would be not to work in it?—That is the only way to prevent it.

7071. Do you suppose that a miner would give up his work because he had to work in bad air?—I believe that some would, and that others would not.

7072. Do you not think that that would depend very much upon whether they could obtain employment elsewhere?—Perhaps so. It would depend upon what they were allowed to get in those places; where the pay is better in poor air ends, for the sake of that they will work there.

7073. You have stated that accidents happen very much from the men being reckless?—Yes.

7074. But would you not consider it right at the same time that every precaution should be taken to prevent the occurrence of accidents?—Of course, and they have got everything for that purpose; for instance, in the charging of the holes we have provided wooden sticks to put in on the powder instead of brass or copper bars; some have iron bars to tamp with; but we have wooden sticks to put in the tamping on the powder.

7075. Do all the men use them?—No, they will not do so; but they ought to do so.

7076. Have they any copper tamping rods?—Yes.

7077. Is there any danger in the use of them?—Yes, I think so.

7078. Will a copper tamping rod strike fire?—They have done so.

7079. Have you seen that done?—I have seen men who have done it in our mine. We were not in the habit of using anything else; perhaps with a little brass with it.

7080. Where did you procure those copper bars?—They were made in the mine; the bottom end of it is copper, about two inches long, with a bar of iron.

7081. Might it not have been some other part of the tamping bar that struck the fire and not the copper end?—It might have been.

7082. (*Mr. Kendall.*) Did you ever know an instance in which a man has refused to work in bad air, or when he has been compelled either to work there or to leave his work and the mine?—Never.

7083. Did you ever know a man complain of bad air, in order to get rid of a bad bargain?—Yes, I think I have.

7084. (*Chairman.*) I suppose that a man with a large family to maintain and not likely to get work elsewhere, would be obliged to go on working where he was, although the air was bad?—No; I do not think so in this part of the country. I cannot, of course, answer for other parts of the country.

7085. Have you never heard of men being urged to drive on by an additional payment being offered to them?—Never.

7086. Do you think that the men are not tempted to do so by a higher price being paid for their work?—Yes.

7087. A higher price is paid for it, is it not?—Yes. I have just stated that I cannot answer for other parts of the country; then they reduce the number of men from two or three in an end to one.

7088. (*Mr. Holland.*) Is it not very bad policy to have bad air in a mine?—Yes, of course it is.

The witness withdrew.

Mr. Alfred Chenhalls examined.

7089. (*Chairman.*) Are you in charge of any mine in this district?—No, I am not.

7090. Have you lived in this district for some years?—Yes.

7091. Have you been connected with mines?—Yes very extensively.

7092. As a shareholder in mines?—Yes.

7093. Are you a shareholder in mines in this dis-

St. Just.

Mr. A. Chenhalls.

31 July 1862.

trict, or in other districts?—In this district principally, but I am in other districts also.

7094. Have you turned your attention to the working of mines especially?—Yes; it would have been impossible indeed for me to have done otherwise; it is always before me.

7095. Have you been much underground?—I have been underground occasionally.

7096. With what mines especially are you now connected in this district?—Wheal Owles, Levant, Botallack, and Bosorn, as an adventurer; a mine now called St. Just United, Bosweddan, Boscean and Bottowal United, and Carnyorth, as a lord.

7097. In any of these mines is there a man-engine used?—In the Levant mine there is.

7098. Are any other means employed to enable the men to go up and down in any of the other mines?—At Botallack they have a railroad, I should rather call it, than the skips, in the diagonal shaft.

7099. How long has that been in operation for the conveyance of the men?—For about four months, I should think; but I believe they have really not put on their proper waggon, unless they have done it very recently; there is a waggon that we intend to employ purposely for the conveyance of the men.

7100. Is it to be drawn up by a single linked chain?—Yes.

7101. It will go down an incline?—Yes; I have been to the bottom of the mine in a waggon.

7102. Are there any other mines in which there are means of going up and down for the men?—I have heard that they intend to employ a skip with patent catches in the event of the chain breaking, so that the skip may be secured from falling in one or two of the mines; but I believe there is none now in operation.

7103. Is a wire rope used at all in any of the mines?—We used it in the Levant mine, it cost us about 500*l.* as an experiment, and it altogether failed.

7104. The wire rope failed?—Yes, as an experiment. We had not the perpendicular shafts that a wire rope should be employed in; the angles of the shaft told very much against the strength of the rope; the friction that took place soon wore it out, and we have had several awkward breakages, and considerable delay and expense.

7105. Are the underlies very sharp?—Yes, in some of the shafts, although we thought that this was a pretty good shaft for employing it in; but we found even there that the underlie was too great.

7106. Had you guide rods for the skip?—Yes.

7107. And pulleys or rollers for the rope?—Yes, we had rollers for the rope at every angle.

7108. And yet you found that the rope wore out?—Yes; it was passed through a barrel of tar or of composition to preserve it and to prevent its wear as much as possible, but it was with us altogether a failure.

7109. Was it by friction that the rope was worn out?—Yes.

7110. Was that the only mine in which a wire rope has been used?—Yes, in St. Just.

7111. What means do you employ now for drawing up the skips?—We employ there a flat hempen rope.

7112. Do you find that that does not wear out so much?—Yes; it serves us much better. We had a flat hempen rope prior to the introduction of the wire, but Captain Evans, the managing agent, from the neighbourhood of Redruth, thought that he would be, I suppose, up to the age, and as the wire rope had been introduced so much in the coal districts, that he would try it here also, and we judged that we had made a good hit for a short time, but we soon found ourselves in difficulties, for shortly we had one or two extensive breakages, and I would warn others against ever attempting the thing again. At St. Just we did it under advantages that some mines do not possess.

7113. (*Mr. Kendall.*) This has been a mining district for hundreds of years, has it not?—Yes.

7114. I believe your family has been here for hundreds of years?—Yes.

7115. They have been miners or mixed up with miners?—Yes.

7116. I suppose you are as much mixed up with mining as any of your ancestors were?—I have about an eighth part of the Wheal Owles.

7117. You have not a less interest in mining than any of those who have gone before you?—No.

7118. Perhaps a large interest?—A large interest.

7119. Do you look over your own mining property?—Yes.

7120. You watch your own bounds, and you look after your own speculations?—Yes; it would be impossible for me to do otherwise, for living here I really cannot be but a miner theoretically. The inquiries which I have frequently to make after my own property lead me into all kinds of questions relating to mining.

7121. You are acquainted with all the vicissitudes of a miner's life from necessity?—Yes.

7122. Is the miner, in your opinion, a shrewd man?—I hold him to be a very much more intellectual man than the cider-drinking population of Devonshire.

7123. As far as you have seen, is he or not careless of life?—I heard the evidence of a very extensive mine agent this morning, and I should be disposed not to endorse to the full extent his views in reference to the carelessness of miners as to life. I have no doubt that there is a great degree of carelessness amongst them, especially on the part of the young and impulsive, and I dare say that there are occasional instances, such as were adverted to this morning, but I could not endorse the opinion expressed, to its fullest extent; I believe that the great bulk of our people are careful of human life.

7124. But so far as the evidence which you heard went to show that the miners would rush into ends before the powder smoke was cleared away, breathing in consequence a quantity of pernicious smoke, you do not impugn that evidence?—I did not hear that evidence.

7125. From your experience, do you think that the miners in their anxiety to ascertain the effect or success of their blasting, frequently rush too rapidly into the ends?—I believe that the boys are tempted to do so pretty frequently; but as the miners advance in life, I have reason to believe that a consideration of their own health, besides the necessity for a very proper and seasonable cessation from labour, would induce them to stand without for a time, and not hastily and recklessly thrust themselves into an end before the smoke was properly cleared away.

7126. With regard to ventilation, do you go down much into mines here now?—Not much.

7127. As far as you hear, and from looking at the plans, do you think that there is much improvement, as compared with past times, in the ventilation of the mines?—I should say that there is very considerable improvement.

7128. Are you of opinion that the mine agents think it not only economy, but the right thing to do, to have their cross-cuts more frequent, in order to provide better ventilation?—I believe that our mining altogether is carried on with greater consideration for human life both above ground and beneath the surface.

7129. You must have had considerable experience from being mixed with so many mines, and do you think that justice is done to the miner with regard to his subscription to the clubs?—I believe that the exceptions to fair play would be very rare; in fact I have only heard of one or two instances in which the mine agents have been challenged, and upon investigation I have found that there has been another side to the statement which the men had made.

7130. You mean this, as I understand you, that the balance has been against the adventurers, and not in favour of the men?—The men said they were unfairly dealt with as to the clubs.

7131. Have you ever known an instance in which

a profit has been made by the adventurers out of the miners' money?—I never have known such an instance.

7132. (*Mr. St. Aubyn.*) You have spoken of a wire rope having been tried in the Levant mine?—Yes.

7133. Are the shafts straight in that mine?—No, they have an underlie.

7134. I suppose that the rope passed over rollers?—Yes, at the angles.

7135. Would the same objection apply to the employment of wire ropes in perpendicular shafts, as in the case of underlying shafts?—I think not; they are in almost universal use in the Welsh collieries, which seems to confirm that view.

7136. In cases where there are perpendicular shafts, you think that wire ropes might be used with advantage?—Yes.

7137. Something has been said in the course of the evidence given to-day about tamping, and about sand being used to fill up the holes instead of stone; can you give the Commission any information upon that point?—At Botallack there is a rule laid down by the agent, at all events in his dealings with the men, that they shall take sand down into the mine for tamping instead of using any stones. They think that there may be inequalities of size in the stone, and, if roughly and hastily pounded up by a hammer, it seems to me that it would produce attrition and fire more generally than the fine sand will in which there are no large cubes of felspar to cut the fuze and so endanger life.

7138. Has this plan been in operation for a long time?—Yes, for years.

7139. Has it been found to answer in all respects?—I could not say definitely that no accident has taken place in a mine whilst it has been used, but I know that where persons have neglected it in the Botallack mine a hole has gone off suddenly.

7140. But you do not know of any case in which an accident has occurred through using the sand?—I have an imperfect idea of one such case occurring, although I cannot call it to mind so as to speak definitely upon it.

7141. Are you of opinion that it would be conducive to the safety of the miners generally if the sand was more generally used?—I have a strong conviction that it would be conducive to the safety of the miners generally; it amounts to positive certainty in my own mind.

7142. Speaking of the district generally with which you are well acquainted, should you say that the miners here were a healthy body of men?—They are healthy as a mining population.

7143. From what you know of them, do you consider them to be more healthy than miners in other districts in the county?—Yes, I do, especially as compared with the Redruth district where I have mining property.

7144. Upon what do you found that opinion?—Upon the knowledge which I have obtained by a pretty extensive acquaintance with them as to the numbers of really infirm persons whose health has broken down early in life, and from my intercourse with the miners who have come into our neighbourhood, and who formerly worked there.

7145. Have you found that the miners who have come from other districts were in better health, while working in the St. Just district than in other places?—I have presumed as much, because they confess that they have less water in the mines, and consequently they are not so subject to rheumatic ailments as they are in the eastward part of the county where they are almost amphibious.

7146. Have you observed that the miners' disease, or, as it is sometimes called, miners' consumption, is prevalent here, as compared with the other districts in the county or not?—I think it is less prevalent in the St. Just district than in Redruth. Our mines, with one or two exceptions, are not copper mines, and the copper mines we hold to be on the average warmer and more unhealthy than the tin mines.

7147. Whereas the mines in this district are chiefly tin mines?—Yes, they are chiefly so.

7148. Upon the whole you would say that the working in this district is more conducive to health than it is in other parts of Cornwall with which you have had an opportunity of comparing it?—Yes.

7149. Will you be kind enough to state briefly to the Commission what are the causes in your opinion of that difference?—In the first place, I would say, that as compared with other districts, in the tin mining districts the heat is not so intense underground; I have every reason to believe that our winzes are sunk here more numerously than they are in the average of the mines in the country.

7150. And by that plan the ventilation is improved?—Yes, of course it would affect the ventilation, and at the same time our mines are not so deep as the mines of the Gwennap district, including some parts of the neighbourhood of Redruth about Carnbrea. Our miners, from the little quantity of water there is, can work, generally speaking, in more comfortable circumstances with dry clothes on, whereas they would be deluged in some of the mines of Cornwall.

7151. Then it is partly from natural causes that your mines are more healthy, they being drier and cooler than other mines, and partly also from improved ventilation?—Yes.

7152. You stated just now that the copper mines were considered less healthy than the tin mines, what in your opinion is the ground for that assertion?—I cannot give you a reason why it should be so, but general experience, I think, will show that that is the case. In the Botallack and the Levant mines, which were the richest and full of copper, it was found that they were the hottest for working in, and some of our miners say that they know almost from the rise of the temperature that copper is near.

7153. Do you know whether there are many more old men working in your mines than it is usual to find in other districts, or whether the men are older who are working in the mines?—I have never had an opportunity of judging from statistical information, but the number of wind-broken people about Redruth who are unable to go underground, and are suffering from bronchial or consumptive complaints, seems to be vastly greater than in our neighbourhood.

7154. Have you never made any observations for statistical purposes yourself?—No.

7155. You cannot say perhaps whether the assertion which has been made, that the average age of all persons working in the St. Just mines is 26 years, is correct or not?—No, I cannot.

7156. (*Chairman.*) You have talked of rheumatic affections prevailing amongst the miners, to what district is that especially confined?—Wherever we find it here we find that it has been from early thoughtlessness in reference to working in sumpts and wet places.

7157. But in what district should you say that these rheumatic affections especially prevail?—In the districts of course where water principally prevails. I should say in the Gwinnear, Camborne, and Redruth districts, and in Illogan.

7158. (*Mr Holland*). Do you refer to rheumatism in the limbs or to rheumatic fever?—Rheumatism in the limbs.

7159. (*Chairman.*) Are there many men out of work now in St. Just who are suffering from miners' disease, or a complaint of that kind whom one could see?—Yes, I know of one or two.

7160. You say that the improvement in the ventilation of the mines has been very considerable of late years, in what way has that improvement been effected?—By sinking winzes within shorter distances, and in fact from a greater consideration for life than formerly was shown; but I believe that it has also been helped to a considerable extent by the employment of waggons upon railroads underground. It is well known that where waggons are employed

ST. JUST.
Mr.
A. Chenhalls.
31 July 1862.

the circulation of the air caused by the waggon passing half-a-dozen or a dozen times through a level is very considerable, and much more than where the air has not been circulated by any such movement.

7161. Then it is the circulation of the air in the mines that has been increased ?—Yes.

7162. Has the passage of the waggons through the levels had any effect in getting rid of the foul air from the mines by driving it out ?—Unless you move the air it would otherwise lie sluggishly underground, as a dead, damp, and poisonous atmosphere ; it would continue there for perhaps any length of time ; but the waggons by moving backwards and forwards have vastly improved the air.

7163. So that what you consider improved ventilation is a mere free circulation of the air underground ?—Yes, getting away the bad air and helping in the new. In all changes of that kind a beneficial effect is produced.

7164. Have you ever known of any experiments being made to ascertain whether air is expelled or drawn in by the movement which you have described as caused by the passage of the waggons through the levels ?—No ; but I know also that the currents are determined to some extent by whether the wind is in the direction of the deep levels of the mine going out to sea, or in the sides of the cut. I have known the circulation of the air to be greatly quickened by the direction of the wind.

7165. Therefore at times, when the wind does not set in that direction, or when there is not much wind, the ventilation would be more imperfect ?—It would be not so good. The Commissioners will have information given to them as to the Levant mine, they get the circulation on to the ends extending furthermost under the sea. They have put down upon the winzes between the shaft and the ends a sort of doors one after another, so that they have not allowed the draught to pass until it was sent on to the very extreme end, almost to the last winze in the end, and there they have made it a chimney.

7166. In the Levant mine they have used means to direct a current of air through it ?—Yes.

7167. Is that generally the case in other mines with which you are connected ?—Mr. Boyns says that in Wheal Owles, and I have no doubt that he is correct, they have done it in one or two cases ; but they have so many winzes down there.

7168. But it is not generally the case ?—No, it is not, and it is by this arrangement that the ends in the Levant mine have been driven out under the sea ; there were no means for it, excepting by ventilation in this way; we could not sink down a perpendicular shaft to the sea.

7169. If the means you have referred to answer in that mine, would it not be an advantage if they adopted the same principle in other mines ?—Yes ; if the same necessity existed ; but usually where we can command a proper surface, shafts are sunk down for a moderate distance where they have not to go, as in one or two of our mines, a quarter of a mile or a third of a mile under the sea, without the possibility of sinking a shaft

7170. In other mines which do not run under the sea, do you think that the shafts and winzes provide sufficient ventilation ?—Yes, I am satisfied that there is nothing wrong in that respect.

7171. Have you ever been in a close end yourself ?—Yes.

7172. Where a candle would not burn ?—I have been in a place where the candle has been inclined to go out, but not where it would not burn.

7173. Is there any way of improving the air when that is the case ?—The only way is by sinking winzes where it is possible, and by making a double current, which is sometimes effected by bringing a bolt into the bottom part of the level, and by throwing air in by artificial means, by fans, through tubes ; we do that in a little mine, now called Bosorn and Bollowall United mines.

7174. You bring the air in from the surface ?—It is brought in through the adit level. We are driving an adit to intersect the lodes which we believe to be before us ; we are in this way doing our very utmost to avoid being compelled to sink a shaft for the purpose of extending this level, and cutting these lodes.

7175. What is the machine that you employ to force in air ?—A fan.

7176. How is that fan worked ?—It is worked by a boy, I think, turning a wheel.

7177. Where is the fan placed ?—It is placed in the level underground, opposite the tubes that convey the air into the level.

7178. How near is any place from which the air is obtained ?—There are shafts coming down to the adit.

7179. How near is it ?—The fan is placed where another adit intersects, and where there is a considerable quantity of air coming in.

7180. (*Mr. Holland.*) By that means you send the air in from the adit to the level ?—Yes; there are two adits coming together, and through one of them a good draught comes ; sometimes we do not use these at all, but we take a piece of canvas and use it as it is used in a steamer to cast air into the boiler room.

7181. They use the canvas as a windsail ?—Yes.

7182. (*Chairman.*) The fan, you say, is worked by a boy ?—Yes.

7183. I suppose three boys work it in succession, one to each core of men ?—Only one can work there.

7184. Is there not some one to turn it for the three cores at work during the 24 hours ?—No; only one man can work in the end in the 24 hours.

7185. How long does he work there ?—For about 6 or 8 hours.

7186. Is he then relieved ?—No.

7187. It is then worked only for 6 or 8 hours in the 24 ?—Yes. This fan was ordered by the adventurers to be put in there, and the captain was ordered to increase the men to two in the ends. I am speaking now under the conviction that the captain carried out the order that was given, for I really cannot speak definitely as to the matter.

7188. Do you know when this order was given ?—The order was given several months ago.

7189. To the best of your belief, has it been carried out ?—Yes ; and if it has not been carried out I know that that is really the means by which the air is carried in.

7190. But you do not know whether it is carried on now or not ?—No.

7191. With regard to the club money, is the same system adopted as to the club money in all the mines with which you are connected ?—The clubs are differently established ; the miners have recently taken upon themselves to conduct the clubs ; they have insisted, by a sort of rise in one or two cases, upon having the control of their own moneys, and that the agents should no longer govern them, or the adventures, in that respect.

7192. In which mine has that happened ?—In Balleswidden and Boscean and Wheal Castle.

7193. What do the miners contribute to the club in those mines ?—They contribute 1*s.*; I think it is 6*d.* each to the burial club, and the other 6*d.* to the sick club or the hurt club.

7194. In those clubs do the men receive relief, either when they are sick or when they have received a hurt ?—It is given to them for a hurt, and for any ickness which can satisfactorily be traced to a hurt which they have received in the mine. Difficult cases are left to the committee.

7195. How long has this been the system at work in these mines ?—At Balleswidden they have partially returned to the old system ; they have allowed the purser to come in conjointly with Mr. Searle whom they selected there under their own control; they have partially yielded the point in that respect, but it lasted, I should say, for four or five years, and it still exists in Boscean and Boswidden.]

7196. In the other mines the clubs are still under the control of the adventurers ?—Yes, throughout the

parish. I believe there are no other exceptions than the ones I have referred to.

7197. Are you aware of cartridges being used for the purpose of blasting instead of the powder being poured in loosely ?—They are very rarely employed in St. Just.

7198. In your experience they have not been used? —Very rarely.

The witness withdrew.

Mr. John Nankervis examined.

7199. (*Chairman.*) You have charge, I believe, of the Levant mine ?—Yes.

7200. Have you charge of any other mine ?—No.

7201. The Levant mine is a tin mine ?—Yes, and copper, or both.

7202. How many men are employed underground in that mine ?—On tut-work we have 70 men and 15 boys.

7203. Have you already sent in a return to the secretary ?—Yes.

7204. Has the number of men been reduced from the time when you sent in that return ?—No ; that is about the number at present.

7205. What is the greatest depth which has been reached in the Levant mine ?—245 fathoms.

7206. Are there any hot levels in that mine ?—Yes ; we have some that are pretty warm.

7207. Have you tried the temperature of any of them ?—Not very lately ; we have had it at about 70°, I think.

7208. Was that the temperatue in the level generally, or only at one end ?—It was one of the warmest places in the mine, as we considered.

7209. Was there copper or tin there ?—We had copper.

7210. Do you consider that the copper has anything to do with the increase of heat there ?—We think so.

7211. Has any experiment ever been tried in order to ascertain that fact ?—There was some years since, but there has not been of late.

7212. What plan was adopted in order to test whether the temperature was higher where the copper was than where the tin was ?—We considered the copper ore to produce the heat more than the tin.

7213. Was that in granite or in killas ?—Killas ; but we had it in granite too in parts of it, but principally killas.

7214. Is there any difference in the heat between the parts of the mine that are in granite and the parts that are in killas ?—Yes, we generally find it most warm in the killas.

7215. (*Mr. Holland.*) At the same depth ?—Yes.

7216. (*Chairman.*) Is it colder where the granite is ?—Yes.

7217. Have you ever seen any cold damp where the granite is ?—We are not troubled with it much in our mine.

7218. Have you ever seen it any where ?—No.

7219. How do you ventilate your mine ?—We ventilate the mine by driving two levels, and sinking from one to the other.

7220. While you are driving the levels is the ventilation good before you have driven them and made winzes between to connect the two levels ?—If we want assistance we put in a machine occasionally, and at other times we put in a stool in the back to make a turn in the draught.

7221. How do you know when it becomes necessary to do that ?—By practice and being trained up to it, as the men get into work they know the heat, and they judge by the light of the candles as well ; they feel the perspiration coming on, and they understand it by practice.

7222. They judge by the candle when it will not burn well ?—Yes ; when it will not burn freely.

7223. Have you resorted to the means you have spoken of ?—Yes, when it is so warm, the men sweat so much that they cannot exert themselves as usual, and then we assist them with an air machine, which has a wooden board at the bottom, and is like a conduit pipe, and they can take the air from the winze ; at other times we take the back away, and put in stools.

7224. Which do you think is the best mode of supplying air ?—That depends upon circumstances, if the ground is such as to be able to take it away over head, it answers two purposes, putting stools to work on and to ventilate too ; otherwise we put it in the bottom, and that is a less expense.

7225. Is there any water there ?—There is very little generally speaking in our mines.

7226. If it is put on the bottom is it not more likely to be stopped up ?—It requires attention to clear it out when it is put in the bottom; it is covered over, to prevent the stuff getting into it.

7227. Is it looked to every day ?—Yes it is, generally.

7228. Does the captain of the mine examine it every day ?—He may not be there every day, but when he comes and goes he sees that everything is all right.

7229. How does he try it ?—By putting down a candle there.

7230. In order to see whether the air is coming through ?—Yes ; he can put his head down.

7231. If he found that the air was not coming, he would think that there was something wrong ?—Yes.

7232. Do you think that that plan is as good as the hand machine ?—It is cheaper, as the hand machine requires somebody to work it ; there must be manual labour connected with that, a boy.

7233. It takes three boys in the course of 24 hours ?—Yes, we work about six hours, when we set the work on piece work ; a tribute-man can work seven or eight or nine hours if he chooses.

7234. Does the man pay the boy, or do you pay him ?—If it is tribute work, the man will pay the boy ; but very likely if there is a piece of work, and we set it cheap, we provide a boy to keep the air right.

7235. If it is tribute work the man will pay for the boy ?—Yes ; he must pay all the expenses then.

7236. It depends, I suppose, upon whether he considers the air too oppressive ?—We will not let them work without the air is proper.

7237. I suppose if a man did not feel any inconvenience it would be considered unobjectionable ?—If he does not complain, we examine things when we go there ; he might complain unless we went to examine the thing for him.

7238. It would be an object to him, would it not, to save the expense of the boy ?—Yes ; but if we see that it is necessary, we must have him put there.

7239. Do you make the miner find the boy to do the work ?—Yes, and we give him a price in proportion to that.

7240. Would you set a boy to work for him, or would you say you must find a boy ?—He must keep the machine going for himself, and get a boy.

7241. Suppose you had to set to a tributor so much, on the supposition that the air was bad, and he must therefore have a boy, how would you compel him to employ a boy ?—We should tell him what we thought was necessary, and it would be at his own expense.

7242. How would you make the tributor employ the boy to turn the fan when you thought it necessary? —If we wished to compel him we could fine him, or we could stop his pitch and threaten to take it away from him if he did not obey us in what we thought was necessary ; we could take his pitch away or not let him work.

7243. Supposing he had a bad pitch ?—He would be willing then to leave himself.

7244. If there were no other means of ventilation

would you put in for him a soller ?—We do that ; we have men to do it at the adventurers' expense.

7245. For the purpose of preventing accidents in blasting with what do you supply the men ?—With a wooden instrument.

7246. Do they use it ?—Yes.

7247. Do they always use it ? — Perhaps not always.

7248. What do you do if they do not use it ?—We cut them off the club ; but any man might use the things provided for them gratis.

7249. If an accident occurred to a man from his not using the wooden instrument he would forfeit his club money ?—Yes.

7250. Has that ever happened ?—Yes, occasionally.

7251. Have you ever stopped the club money from a man ?—No ; we have never been present to know whether it was so or not ; but this is a check that is put on the people. We let them know that they are in danger of losing their monthly subsistence-money ; we have had it posted up, but we have not put it in practice. If we saw a case of the kind we should act very likely upon it.

7252. Judging from your experience, is that oaken rod quite sufficient for tamping ? — Yes ; but we allow them to use the iron bar after they have settled in two layings of tamping on the powder with the wooden sticks, should they think it necessary.

7253. Suppose there is any powder lying scattered about the hole, and the tamping is put on with a rod, might not the powder be exploded by a stroke of the rod ?—They have a swabstick, and they get water generally, and they damp the end of that stick and put it in to clear away the grains of powder ; this is done before any tamping is even put in the hole.

7254. If they do not do that there is danger ?—Yes.

7255. Would it not be better if some plan could be adopted to prevent the chance of accident ?—Yes, if it could be done.

7256. You do not know anything of that kind that could be put in practice ?—No.

7257. How often do the captains of the mine visit a level where the men are working in the ends ?—They may visit them perhaps two or three days following, or perhaps two or three times a week, it depends upon what importance they attach to the place ; it is not confined to every day, but sometimes they do it two or three days following.

7258. What happens when a captain goes down into a mine and he finds a level choked up with deads ?—Then the miners are called to account, and they are told, "You must bring your stuff out or we "shall send people to bring it out for you, and keep "the money from you to pay for it."

7259. Does that often happen to you ?—It happens occasionally ; there is not a man hardly who is not liable to do it ; they will leave it there sometimes at a sacrifice to themselves if they are not looked after.

7260. You mean, I suppose, that it will impede the ventilation ?—Yes ; and the men cannot work with the same vigour. We have to look into that, for when they are crammed up they cannot exert themselves with the same vigour.

7261. They neglect it, I suppose, in order to save the cost of removing it ?—Yes ; but if they got a boy or some parties to take it away they might do it twice a week or once a week, and we have to guard against their not doing it.

7262. Will you be good enough to furnish the Commission with a copy of the rules in the mines with which you are connected ?—Yes.

7263. What do the men pay for candles ? — 9*d.* a pound.

7264. Are they limited to a certain quantity in a given time ?—Not exactly ; but there is a certain quantity mentioned generally ; and if they are working longer or anything takes place so that they require more they have more supplied to them.

7265. What is the general quantity that you allow the men ?—About 2 lbs. a man per week.

7266. Do you use in the mines with which you are connected any particular kind of powder ?—No ; it is the common powder.

7267. Have you never tried powder that produces less smoke than the common powder ?—There was a powder that was had down here and it was something lighter, but we could not perceive any difference.

7268. I suppose that the other deductions made in the bill are for club money and doctor's money ?—The club money is the men's ; a similar amount goes to the doctor.

7269. Do you deduct so much a month from each man for club money to provide for accidents ?—Yes.

7270. How much do you deduct per month ?—6*d.* a month.

7271. Is that to provide for visible accidents ?—Yes ; that is divided between the parties who meet with visible accidents.

7272. How much is contributed for the doctor ?—6*d.*

7273. Does that contribution include attendance only upon the miner himself, or also upon his family ?—It includes attendance upon himself and his family, except in case of fever, and for the midwife.

7274. Is any deduction made for the barber ?—No.

7275. (*Mr. Holland.*) You have stated that when a level was full of deads, the men could not work with their accustomed vigour ?—Yes.

7276. Is that fact well established ?—Yes.

7277. Is not that a loss to them as well as to you ?—Yes ; but they are anxious to allow a sufficient quantity to accumulate so as to have a full day's work for the person they hire.

7278. When the miners cannot work with proper vigour, you put in a blowing machine, and that is for their benefit too ?—Certainly.

7279. Do the tributors never make any difficulty about paying the boy ?—No. They are glad to have him and to pay for him.

7280. (*Mr. Kendall.*) If you find any difficulty in getting your orders carried out, do you not always either spale or suspend the miner ?—Yes ; or we turn him away.

7281. Do you always do that ?—Generally.

7282. Are you not always obeyed by the larger number of the men ?—Yes. If they work in the mine they must do what we wish them to do.

7283. Is not spaling very common ?—Yes ; quite common ; and it was before I was born, I believe. The first spale is 2*s.* 6*d.*

7284. (*Mr. Holland.*) You are the judge of how a pitch ought to be ventilated, and you do it in the way that you think best, and the miners submit to your decision without question ?—Yes ; we have it put down in our rules. We fine a man for not obeying our orders, in the first instance 2*s.* 6*d.*, and for the next offence 5*s.*

7285. Can you equally spale both the tributors and the tut-workmen ?—Yes ; or we can do away with them. We say to them "You must attend when you "are called upon, you must submit to what the agents "think is best to be done".

7286. Is it not very good economy to furnish a good supply of air to the miners ?—Yes.

7287. Does not that save them loss of time and loss of exertion ?—Yes ; we have to look into that ; and it is for our benefit to do it ; that is one of our principles to get the places well ventilated; we then get more work for the money.

7288. Your plan is to use a fan machine worked by boys, and to put in sollers ?—Yes ; and in sinking down winzes from level to level.

7289. Until a winze is sunk, or a rise is driven, when the air is close have you any other plan besides the fan machine and the boy or an air soller ?—Yes; there is one thing that we have, we open a wide level and a high one generally where we intend to go for a great length.

7290. How wide and how high would it be?—Eight or nine feet high, and three and a half or four feet wide. Then we put down a railroad, and lay in a tram waggon, which, pushing to and fro, makes such a circulation, that it does assist us in getting the air in better.

7291. (*Chairman.*) By that means you make the air circulate to the bottom of the mine?—No; only at the level where that plan is adopted.

7292. What do you call a long end; how far distant from a shaft, or from a winze?—We go by the railroad sometimes 30 fathoms and sometimes 50 fathoms, and perhaps 60 fathoms; sometimes we work 70 fathoms, the air coming from one draught.

7293. (*Mr. Holland.*) Without a winze?—Yes; we can work so, it depends upon what draught you have at the mouth of the level, and whether the air is pure.

7294. (*Chairman.*) If the air is pure you can go 70 fathoms?—Yes.

7295. (*Mr. Holland.*) Can you keep the air cool to a distance of 60 or 70 fathoms?—Not in places to work all the time; in those places we generally calculate to work for six or twelve hours out of the 24, for the rest of the time it is left to cool. If we wanted to work longer time we should very likely have to apply the machine and to sink winzes if we could.

7296. How long does it take to sink a winze?—That depends upon the distance you are going to sink it.

7297. What is the longest time that it has taken you to sink a winze?—It depends also upon the hardness of the ground; three months sometimes, or more or less, and it depends also upon the number of hands.

7298. Until that winze is sunk, what do you do?—We abandon the end perhaps, if we do not think it will do to keep it on.

7299. When you are sinking a winze is not the air bad at the bottom of that winze?—Then we use the fan machine.

7300. How do you throw the air to the bottom of the winze?—By the air machine and pipes; we put down pipes in order to carry the air to the place where the men are working.

7301. What length of pipes do you run from the end of the air machine?—I think we have driven 100 fathoms.

7301*a*. With a boy driving the air machine at the end?—Yes.

7302. Do you know what quantity of air you drive in?—No.

The witness withdrew.

Mr. Henry Boyns examined.

7303. (*Chairman.*) You come from the Botallack mines?—Yes.

7304. Have you been underground to-day?—Yes.

7305. How long is it since you have had any means of conveying the men down your incline?—About six months.

7306. Formerly the mine used to be very hot in places, was it not?—Yes, the part of the mine which is ventilated now by our diagonal shaft was 91°; very warm.

7307. What is it reduced to now?—To about 70°.

7308. Is it a copper mine?—Yes.

7309. Is there any tin in it?—Yes, there is.

7310. In the part you have referred to?—Yes, there is both tin and copper.

7311. Does that diagonal shaft communicate with other shafts?—Yes, through the levels.

7312. That is the way in which the ventilation has been effected?—Yes; the levels being communicated in long distances from one shaft to another.

7313. When you speak of long distances, do you mean the distance from one shaft to the other?—Yes.

7314. You think that this helps the ventilation?—Yes; there is a better balance of the air.

7315. Have you any shaft that is an up-cast, and any shaft that is a down-cast in your mine?—No; we have five mines in connection with the Botallack mine on different lodes, in each we have more than one shaft, so that the ventilation is good for driving out the impure air.

7316. Is there one or more of those shafts which are especially up-cast shafts?—I do not understand the term.

7317. I mean a shaft by which the air goes out, it being drawn in by others?—Yes; sometimes it is altered by a change of wind, but there is no rule for it; excepting in the Crown's part being under the sea, the engine and other shafts are the down and the diagonal the up-cast.

7318. But the air below the sea always goes down one shaft, does it not?—Yes, and comes up the other.

7319. (*Mr. Kendall.*) How far are you able to force air in?—We can force air in to a distance of 200 fathoms, if necessary.

7320. How far have you forced it in?—To a distance of about 150 fathoms by a small machine, that is the greatest case that I have known.

7321. (*Chairman.*) How is the machine worked?—By a boy at the rate of 10*s*. a month.

7322. What is the depth of the shaft?—190 fathoms vertically and 370 diagonally.

7323. What is the length of the level?—The 180 fathom level is 400 fathoms from the vertical shaft and reaches the diagonal at 280 fathoms.

7324. What was the object of making the diagonal shaft?—There were three reasons for it: the first was to explore the productive part of the mine which took a diagonal course from the surface, the diagonal shaft being sunk on the lode; the second was to carry on the ventilation, without which we could not work the mine; and the third was to draw the men up and down through the shaft.

7325. How do you contrive to ventilate beyond the point where the diagonal shaft reaches the level?—By winzes.

7326. How far had you driven the level before you put in a winze?—About 50 fathoms in the Crown's part; in some parts we have gone as far as 100 fathoms.

7327. Was the air before you came to the 50 fathoms at all poor?—It is generally close, but much depends on the freeness of the air behind.

7328. Suppose you were driving away from a shaft or a winze 50 fathoms, should you consider that far enough?—Yes.

7329. It must be close there, must it not?—Yes, but it depends upon circumstances; if we work only one pair a day it makes it much more acceptable to work in; if we have three pairs of men a day at work it is necessary that something better should be done.

7330. Do they work 6 or 8 hours a day?—They work 7 hours a day, but there is no blasting goes on then; a man can leave and he is not affected in any degree whatever.

7331. How long is it before the smoke gets out of that sort of end?—Three hours perhaps.

7332. You can only work one pair of men a day?—In following that rule we can drive our ends further without ventilation, not doing injury to any person.

7333. When you have foul air the men do not drive so fast?—No; if a mine does not need forcing we can take a longer time about it, and do it cheaper; we can do it more effectually, and at less expense, but if we must force it we must put in superficial means of forcing the air, then we save the expense of

St. Just.
Mr. H. Boyns.
31 July 1862.

sinking winzes, and the men are better off even then.

7334. They are better off then?—Yes; they are not affected by the blasting.

7335. Is there any accumulation of bad air when the men go down on the Monday, or is there any damp air?—No; the air is as free as it is in this room. If you go to the bottom of the diagonal shaft the air is as free as it is here.

7336. But it is not so at the end of the 50 fathom level?—No.

7337. Does the diagonal shaft go the bottom of the lowest level?—Yes.

7338. Have you ever worked in other mines?—Yes.

7339. Have you worked in what they call a close end?—Yes; I worked as a miner for 16 years.

7340. How did you know that the end in which you were working was close?—I felt the want of draught, and then by the burning of the candle.

7341. Which showed it to you first?—The candle. We feel that it is a little warmer, but we can generally breathe freely.

7342. You see that the candle does not burn so well?—Yes; as soon as we are in a close place, generally speaking, we have a little warmer atmosphere, and there is not that current of air to be felt, and the perspiration is more free.

7343. After leaving a close end, do you feel affected when you are climbing the ladders?—I do not think it makes much difference in that respect; if a man works hard he becomes exhausted, but the climbing, I believe, is an evil amongst us. I think that we climb rather too fast, generally speaking.

7344. What causes do you think chiefly interfere with the miners' health?—The first cause no doubt is the closeness of the air. The next is climbing the ladders; that has proved very injurious to our young men in walking up so fast, which they often do, the heart is greatly affected. I was down 200 fathoms yesterday, and I found that I could climb the ladders very comfortably, and felt very little exhausted when I got to the surface after doing my work of examining the mine. The third cause is the high state of perspiration produced, and then coming into a cold atmosphere near the Atlantic, and then, perhaps, having miles to walk to their homes.

7345. And when they come up to the surface, having far, perhaps, to go to the changing house.?—That would be bad; but our situation is considerably improved in that respect.

7346. A good changing house, I presume, is a matter of great importance?—Yes, that is clear if necessary precautions are taken.

7347. You think it is of importance to have a good changing house?—Yes.

7348. Have you got a good changing house?—We have them warm; but I do not think that our condition is altogether satisfactory on that point. We change in the boiler houses; the engines being in different parts of the mine make it very convenient for the men, being near the shafts and warm to dry their clothes. I think it is preferable in some cases, but I think we should have a little better arrangement than that as a rule. I apprehend that there must be danger, although we have had only one accident from the bursting of a boiler in the neighbourhood.

7349. Where did that happen?—At Pendeen Consols.

7350. When did it happen?—About 12 months since.

7351. Was any man killed upon that occasion?—One man was, but he was not connected with the engine; he was out in the fields and he was killed.

7352. Therefore there is always a liability to danger if the men change their clothes in the boiler house?—Yes; we think so.

7353. How often do you clean out the boilers?—Somewhere about once a year.

7354. Is there any record kept of the time when they are cleaned out?—Yes; the date is put down at once.

7355. How do you judge when it is necessary to clean them out?—From practice, knowing the quality of the water that goes into them. When we cleanse a boiler at any given time, we judge accordingly.

7356. Do you clean out the boilers regularly once a year?—That depends on the quality of the water and the quantity of steam generated in them, and whether the foulness of the water acts chemically on the iron.

7357. Are the rules of the mines stuck up when you set the work?—Yes, there are rules; and our purser at the setting day will say, "Our rules are as usual," unless anything particular is necessary.

7358. Will you be good enough to furnish the Commission with a copy of your rules?—Yes.

7359. Are the rules stuck up?—Yes; rules with reference to the order of working on entering the mine, and giving notice on leaving the mine.

7360. Have you laid down any rules as to the mode of blasting?—We have no other rule than constantly reminding the men on the setting days that we provide for them suitable material, a suitable kind of tamping for blasting, and a certain kind of bar to be used, and we caution the men that if they do not attend to these things and anything happens, and it is proved that it has not been attended to they will not have any claim upon us.

7361. I suppose that in all mines there is a supply of proper tamping?—Yes; in all well-regulated mines.

7362. What is the bar that you have just spoken of?—We have a composition bar.

7363. To serve as a tamping rod?—Yes; the composition is copper principally and lead.

7364. With that bar can you not strike fire?—It is not supposed so.

7365. Have you ever had an accident occur from blasting?—Yes, several; but when I say that, perhaps sometimes not one a year.

7366. Do you suppose that these accidents have arisen from carelessness?—Yes; in the last case there was a great deal of carelessness; there was not proper tamping used in the first place.

7367. That you supply?—Yes; but the men take up just what comes.

7368. How do they carry the tamping down the mine?—They provide bags, and it is sent down by the engines.

7369. I suppose the tamping may become mixed with the refuse?—Not of necessity; we have boxes provided to hold it in.

7370. Have the miners always the boxes with them?—They are supposed to have.

7371. But they have not always got them, I suppose?—I do not say that there are not exceptions, but when there are such a number of men at work the agent's eye cannot always be over them to carry out the rule without exception.

7372. What quantity of candles are allowed to each man?—2 lbs. a week per man.

7373. How much powder is allowed to the miners?—That is at their own judgment and choice.

7374. What is the charge made to the miners for candles?—9*d.* a pound.

7375. How much for the powder?—9*d.* a pound.

7376. What is the contract price at which you get the powder?—It costs us about 50*l.* a ton; about 6*d.* per lb., but it varies in price.

7377. What is the contract price of the candles?—It is about 6*s.* for a dozen pounds, at present about 6*d.* a pound.

7378. What sum do the miners contribute to the club?—It is 6*d.* per man per month, and 3*d.* per boy.

7379. Is that to provide for visible injuries?—It is for any person who is hurt by any means in the mine; it is called the hurt club, not the sick club.

7380. How much is paid for the doctors?—The same amount, 6*d.* per man and 3*d.* per boy a month;

but in that is included the attendance of the doctor on the whole of the family.

7381. Is there anything charged for the barber ?—Nothing.

7382. How are the doctors appointed ?—They are appointed by the adventurers.

7383. Have you any men who have been previously working with you, but who are out of employment just now ?—I do not remember one, we had one man burned but he has followed his avocation in order to get his livelihood since.

7384. (*Mr. Holland.*) Do the tamping tools to which you have referred last pretty well ?—Yes, they last fairly.

7385. Is the implement that you mentioned an iron rod with a composition end ?—Yes.

7386. Are they nearly as durable as iron ?—Yes.

7387. About how much do they cost ?—We charge 1*s.* per bar, the copper I suppose being about sixpennyworth.

7388. What is charged for the whole bar ?—1*s.*

7389. And you say that they last nearly as well as iron ?—About the same. The men are charged a certain amount for the purpose of making them take care of them.

7390. Are not all the tools weighed ?—Yes, and all deficiency they pay for.

7391. In the case of the tamping rod it is the same, I presume ?—Yes.

7392. (*Mr. Kendall.*) You do not weigh out the tamping rod ?—No ; that is charged per piece.

7393. (*Mr. Holland.*) How are the men drawn up in your mine ; in waggons ?—Yes. We have a railroad and a carriage to take the men up, but without a break ; it is drawn up by a chain ; we do not think it safe, and the men do it at their own option; we do not warrant it ; we cannot do that without having a break to the wheel.

7394. At present it is a common tram waggon ?—Yes.

7395. Drawn up by a chain ?—Yes.

7396. (*Mr. St. Aubyn.*) It is drawn up the diagonal shaft ?—Yes.

7397. (*Mr. Holland.*) Do the men like it ?—Yes ; indeed there is a great difficulty in keeping the men out.

7398. Can you get all the men up in that way ?—Yes ; from that part of the mine, which is not one-fifth part of the mine altogether.

7399. Are the men able to perform more work since they have been carried up and down in that way than they did before ?—Yes. I have an idea that the men expend their strength the other way in coming and going, and cannot put it into their work.

7400. What proportion of extra work can they do now ; do you think it is as much as a quarter more ?—From the advantages that we have derived here in the way of extra work from the position of this shaft, we can save more than one-third part ; we do that now, and for one-third less money than before we had that shaft there ; that is partly from economy of toil and partly from ventilation.

7401. Can you divide them at all, and say how much is due to each ?—I think somewhere about one half of it.

7402. Have you any very distinct data for calculating it ?—Not at all. I was never asked the question before.

7403. (*Mr. Kendall.*) According to your present idea, your save about fifteen per cent. upon the labour in consequence of being able to send the men down as you do now ?—Yes ; I should think that is something about it, judging offhand.

7404. What age are you ?—Forty-two.

7405. How long have you been an agent of a mine ?—About fourteen years.

7406. How long were you a miner ?—I was a miner for 16 years.

7407. How do you feel now in your health ; are you as strong as ever ?—I am quite strong for labour.

7408. Who is it that pays the fan boy ?—Sometimes the agents reserve it to pay it themselves, otherwise they make a contract with the parties; they arrange that very generally with the parties engaged ?

7409. Do you find that in order to save the expenses of the boy they ever neglect to use the fan ?—Not if it is insisted upon by the agent.

7410. But suppose you found out that they did so, what steps should you take ?—We should correct it immediately.

7411. How would you proceed ; first, by spaling the men ?—Yes ; but we very rarely do that. I never did it but twice in my life. It is the custom to do it occasionally ; but I do not think it is the right way to do it.

7412. As I understand from your evidence, notwithstanding your mine runs a long way under the sea, yet by winzes which are connected with your diagonal shaft, and with your right down shaft, the mine is not otherwise than fairly ventilated ?—Yes, it is ventilated equal to any mine in the county of Cornwall.

7413. (*Mr. St. Aubyn.*) You have stated that you do not consider the waggon coming up the diagonal shaft on the rails is safe ?—You must understand me to mean without a break we do not think it safe.

7414. But they use it without ?—Yes, they do, but they do it at their own risk.

7415. But how can you feel justified in allowing the men so to come up if you do not consider it safe ?—We say to the men, "If you do it, you do it at your "own risk," that is how we justify ourselves.

7416. But still the miners are under your control ?—We consider that we are no longer responsible.

7417. Have you not the management of the mine ?—We are the agents of the mine ; but, however, the matter has been attended to, and a carriage with a break to it to take eight men is now working with the greatest safety.

7418. In which do you think the miners suffer the most, in the old mines or the new mines ?—In the new mines if in any. The ventilation is not so good as the ventilation in our mines. I could put you under 200 fathoms, where the air is as good as it is here. We have very few new mines here. Our fathers began them for us.

7419. In the new mines you think there is more risk of the men suffering ?—Yes.

7420. From want of ventilation ?—Yes. The difficulty is when we sink the first shaft to get air down any considerable depth without superficial means to force it till we communicate with another shaft. I recollect working in the dark in order to get a communication.

7421. Did you suffer from that ?—The time was nothing to interfere with one ; I do not recollect suffering.

7422. How long were you so working ?—Not more than three or four weeks at the furthest, speaking of the time that it took us to get this communication through. Artificial means were used by using sails to force the draught all we could.

7423. Do you think that miners may suffer independently of the deepness of a mine by merely driving without having a thorough communication with some other shaft ?—Yes.

The witness withdrew.

Adjourned to To-morrow at 12 o'clock.

Friday, 1st August 1862.

PRESENT :

The Right Hon. Lord KINNAIRD, K.T.	RICHARD DAVEY, Esq., M.P.
NICHOLAS KENDALL, Esq., M.P.	P. H. HOLLAND, Esq.

The Right Honourable Lord KINNAIRD, K.T., in the Chair.

Mr. STEPHEN HARVEY JAMES examined.

ST. JUST.
Mr. S. H. James.
1 August 1862.

7421. (*Chairman.*) What position do you occupy?—I am the purser and manager of the Botallack mine.

7422. Have you the charge of any other mines?—Not at present.

7423. Will you state about the number of men in the Botallack Mine?—I should think we must have about 320 or 330, or perhaps 340 underground. There are altogether underground and on the surface over 550 persons, including women and boys.

7424. How long have you been manager?—I bought the mine of the late adventurers in the year 1835.

7425. That was before the diagonal shaft was made?—It is only now put down; it is about three years ago that we commenced it.

7426. Before that was put in it was very hot in parts, was it not?—Yes.

7427. During your management was it in that state; and were you obliged to abandon the working of any part of it?—Not exactly so; but it got very hot, and it would have been difficult for us to have gone on to have followed the ore that was there except we had a diagonal shaft.

7428. At that time, when you were working the mine, how did you manage to ventilate it?—We carried one level after the other, and so made winzes from one to the other. We had no artificial means, except that occasionally we used fans if we were driven to push in a level. We put in a fan where there was good air, and forced it in to suit a winze at such a place.

7429. But since the diagonal shaft has been sunk you are able to work at the ends of the levels?—Yes; as much as you like.

7430. Have you no close ends now?—Not one to my knowledge.

7431. No places where a candle will not burn?—No; and we never had. We were never so bad as that.

7432. How did you judge that the ends were bad?—We found it very hot.

7433. You only judged from the heat?—More particularly from the heat.

7434. Did the men never suffer from working?—I do not think that they suffered to any extent. The only man that I know who suffered to any extent was a man named John Waters; he worked in the worst end of the mine for years, and I think that he is as good a man as we have now.

7435. How did he suffer?—I should suppose that he suffered a little from shortness of breath, but it seems to have passed away altogether now.

7436. How old is he now?—From 50 to 60.

7437. Where does he reside?—Here in Church Town. I think that we can get hold of him in the afternoon. I should like you to see him he has been working with us every day, I think, for 10 years, and I think that he is a strong sort of a man.

7438. And he is now working under ground?—Yes. I never heard a complaint from him.

7439. That is the only man who you think at all suffered from working in Botallack Mine?—I am satisfied that we have had no other working in any close place to any extent whatever. Whenever we have found it close we have always taken care to put in a fan, and iron or zinc pipes, and force in air into the end in such a way that it would blow out a candle.

7440. What is the extreme distance for which a fan has ever been employed to drive air?—I should think that we have employed it for some 70 or 80 fathoms in the latter part of it; of course in the former part it was not wanted.

7441. Is the fan driven by a boy?—By a boy or a man.

7442. Have you employed a boy or a man?—Sometimes a boy and sometimes a man; a boy generally I should think; that was found to be quite sufficient.

7443. How far was he generally from the point where the men were working?—Perhaps it would commence at 40 fathoms, and it might go on to 80 or 90; on one occasion I should think that it went on to 100.

7444. Must the boy continue constantly blowing?—Always while there is a man in the end.

7445. Is there a relief of boys the same as of men?—Yes.

7446. Three corps?—We seldom work three corps; two corps generally.

7447. What are the hours of the two corps?—I do not myself think that they work above five hours in a corps on the average. They may be seven hours from the surface, but I do not think that they are above five hours at the work.

7448. At what hour do they go down?—At half past seven; and they come up at one or possibly half past one and sometimes two.

7449. They are relieved and another corps goes down?—Yes; but in many cases we only work one pair of men; we have not had men enough to do more.

7450. Does it depend upon the state of the ore?—In a great measure it would. If there was anything very particular you would put more and pay them an extra price for pushing on; but with a single pair you can work cheaper than with two, and with two cheaper than you can with three.

7451. If you put in extra men, still that fan gives you sufficient ventilation?—We have always found it so.

7452. What security have you that the boy continues constantly blowing?—If a man in an end did not find sufficient air coming in, he would take out a rope's end.

7453. He would take the rope into his own hand?—Yes.

7454. Does he pay the boy's wages?—Very likely the adventurers would have to pay them; on some occasions they would, and on others not.

7455. According to the bargain which you make?—According to the bargain which we make.

7456. Have you ever tested the air in a close end when the fan has been at work?—I should think that it has been tested many times. I do not recollect that I have done so myself. I never have.

7457. Do you think that the fan is quite sufficient to ventilate any close end?—It will depend upon where the fan is fixed; if the fan is fixed in a place where the air is very good and perfect, I think that it will be sufficient.

7458. I suppose you have worked in and been connected with other mines?—I have been connected with other mines.

7459. Is not a soller sometimes used?—Yes, occasionally.

7460. Do you think that a good mode of ventilation?—Yes; it will carry air a very long way.

7461. Which do you prefer, a fan or a soller for ventilating a close end?—I think a fan better for a short distance; in a very long distance you may have to

resort to a soller, but I hardly think that anything of that kind is required here. We want to drive our levels through the ground. If we omit driving a level, we may leave a bunets, therefore we prefer driving 10 or 12 fathom levels and sinking winzes.

7462. Do you sink winzes for ventilation?—You may discover something by it; but if not, it is for ventilation.

7463. When you drive a lower level, and put in a winze into the upper level, does it ventilate the lower level?—Yes.

7464. Does the draught come down?—Sometimes it comes down and sometimes it goes up; but it will depend upon the wind at the surface.

7465. If it goes up it will not ventilate the end beyond the winze?—It will ventilate the end to some extent, but not to a very great extent.

7466. Do not you think it possible that parties driving an end away from a winze where the draught is up are of opinion that the air is improved when it is not?—No. I think that they can tell it pretty well; but we have another mode, we put in a door to send the air into the end.

7467. Do you think that that is generally done?—Very frequently; it is done on all occasions whenever it is thought to be necessary.

7468. In a well managed mine?—Almost in every mine; it is always done with us, perhaps there are some omissions. Some people, I fear, are not so careful about things as they ought to be.

7469. If it is not done, and if there are not means to secure the air going by doors, or otherwise, to the extreme level, it is gross neglect?—It is neglect, there is no question about that. I was never but once in my life in a place where it was such a close end that a candle would not burn.

7470. Of course you never permit any accumulation of deads in your levels?—As little as possible; there are certain times when it will happen, but we calculate that it is cleared every week, or perhaps twice a week.

7471. In letting the ground to your tributors and tut-work men, is it equally their business to carry the deads away?—Yes, to bring them to shaft.

7472. If you found them accumulating, what would you do?—There would be a noise about it; they would not be paid until they had cleared their work.

7473. Would a man be spaled for it?—No; but there would be a noise about it. I do not think you can spale any men in this place, they would be off to another place; they are just as independent as yourself. All the spaling that you can give them is to say, "If you have not completed your bargain altogether we will not pay you." We cannot spale here, the men are masters here, and they have been masters for years.

7474. When you are in want of men, do they come from other parts of Cornwall?—Yes, from many places.

7475. Then you are never in want of men here?—I believe that we have been in want of men here for many years.

7476. Have you ever taken any steps to induce them to come from another part?—Perhaps we have quietly. If you want men you dare not say so in the mine. Our men are remarkable for their independence. And there is another thing, our men all work single-handed; we have not two men in an end here at a time.

7477. Is not the work let to them in pairs?—Yes; but if there are two men in an end, one comes in the forenoon and the other in the afternoon. He holds the borer with one hand, and beats with the other, and when the hand gets tired with the hammer, the man changes it. That is a reason why the eastern men cannot work with our men here, they must all go double-handed.

7478. Which is the best mode, double-handed or single-handed?—Single-handed men get more money; two men single-handed in an end will get as much as three double-handed men. There is all that difference.

7479. Which would be the best for the adventurers?—Single-handed.

7480. (*Mr. Holland.*) Is that the case in all rock?—Yes, with us, excepting there is something extremely hard. If you are going to drive a cross-cut across a piece of ground at 20*l.* or 25*l.* a fathom, that, perhaps, is a different thing.

7481. (*Chairman.*) Then do you think that that is one reason why when in other parts of Cornwall there are men seeking work, they do not come here because they cannot work single-handed?—That is a reason and a very principal one.

7482. Another reason, I suppose, may be that living in another part they do not like to leave with their families?—No person would leave his home if he could remain at home.

7483. And therefore it would be an expense to them to give up their cottages in other parts of Cornwall to come here?—Yes.

7484. Have you plenty of house accommodation?—Yes, I think pretty well.

7485. But should you have sufficient for any extra men?—I do not know that you would find very much extra accommodation for other men; there is no excess of houses.

7486. Are they principally tut-work men or tributors?—Principally tut-work men. There are more tut-work men than tributors.

7487. Do you raise the ore by tut-work men?—Principally, more than by tribute. When we had the rich bunch of ore in Botallack, I never set one tribute pitch, it was stoped at so much a ton. We made 50,000*l.* profit there, by setting the ore by the ton, and I do not think that any man ever made more than 4*l.* a month by it, so that the adventurers had the whole of the proceeds.

7488. I suppose it is only where you have a good bunch of ore that it would answer to work by tut-work?—It is only where you have a good bunch of ore that it would answer to break by the ton; but we are now breaking all the ore that we are breaking by tut-work, at so much a fathom. Our ground is very rich, generally, and subject to what the miners call "scotches." It would go abroad, perhaps, into a wall of 8 or 9 feet long, and would turn out 10 or 15 tons of ore, worth 15*l.*, 18*l.*, and 20*l.* a ton, and we have had 25*l.* and 28*l.*

7489. What are the tribute men working at principally?—On tin.

7490. With respect to the candles, is there a limited allowance of candles to each man?—I think there is, generally.

7491–2. What do they cost you a pound?—About 5½*d.* or 6*d.*, delivered here.

7493. (*Chairman.*) What do you charge for powder?—9*d.*

7494–5. What kind of powder do you use?—Principally from Kennell Mills, near Penryn.

7496. Does that give less smoke than common powder?—It is common powder.

7497. There are two kinds of powder used in mines, are there not?—There was a sort the other day, which was sent out by Thomas Davey, which was composed of something different; we had a little of it on trial, but our people did not like it.

7498. What is the cost per pound of the powder which you get?—We are charged 6*d.* a pound by the ton. We charge it as high a price as we can in order to induce the men to be as careful as they can.

7499. Is it the same reason with the candles?—Exactly.

7500. But you only allow them, under any circumstances, 1½ lb. or 2 lbs. of candles?—Two lbs. is the most in the regular way; if there is anything extra, so that they work longer hours, they have more candles.

7501. Do you know the quantity of candles consumed in a year in the mine?—I am hardly prepared to answer that question.

St. Just.
Mr. S. H. James.
1 August 1862.

7502. Can you furnish us with it? — Yes; I should think that our supply is something like 50 dozen a week.

7503. Can you furnish us with the quantity of powder? — Yes; we will give you the quantity of powder which we use in a year; we had two tons last quarter.

7504. There is no deduction from the men in your mine for the barber, is there?—No.

7505. With respect to the club, is it an accident club or a sick club?—An accident club.

7506. How many men contribute? — All the underground men.

7507. Do the women and girls contribute?—No; many of the surface men do.

7508. (*Mr. Holland.*) Is it voluntary?—Yes; it is voluntary altogether.

7509. (*Chairman.*) Is it voluntary with the underground men?—I should say so. I do not know that there is any compulsion about it at all. We collect it; but if any person likes to refuse to contribute he is quite at liberty to do so.

7510. (*Mr. Davey.*) Did you ever know a man refuse?—Yes; we had a man who refused some years ago to pay to the club, and I think that that day fortnight he was buried.

7511. (*Chairman.*) Is there also a death club?—Yes; it applies to every person working in the mine, and if Botallack had been the last mine that a man worked in, and he continued his subscription up to pay to the death club, his widow, or mother, or sister, or whoever might be his representative would be entitled to 1*s.* from each of the men.

7512. The death club is different from the accident club?—Yes.

7513. How often is the account of the accident club balanced?—It is never balanced at all. The money is paid and the expenses are charged every month.

7514. Can you give us the amount now to the credit of the men?—There is neither debt nor credit. They are paid every month out of the club. No account is kept of it in any way. The adventurers pay them as they go along.

7515. They are paid if they meet with an accident?—They are paid if they meet with an accident; they are paid 5*s.* a week.

7516. For how long?—Until they get better.

7517. If a man is blind how long does he get the the payment?—As long as he lives, and the mine lasts.

7518. Five shillings a week?—Yes.

7519. Have you any distinct club fund? — We have no distinct club fund. I kept it for some time and I found that the club did not pay, and I thought that we had better turn it over.

7520. When you found that it did not pay I suppose you had had a number of accidents?—I think we had more at that time; that must be 15 years ago.

7521. How many accidents have you had in the last three years?—There was one man killed entirely through his own folly, and we have had two or three others who have shot themselves.

7522. Blind?—One man only.

7523. You mean, by shooting themselves, blasting?—Yes.

7524. The three men are getting that allowance from the club?—Yes.

7525. How many have you as pensioners on the club?—Very few, I am glad to say. I should think that we may have about six altogether, and one of them only worked in the mine two or three days.

7526. Those men would be receiving 5*s.* a week?—Yes.

7527. Have you ascertained how the accident happened with these men who hurt themselves by blasting?—Yes; the one that I alluded to might have been there for a month. I do not think he was there so long. I have for very many years kept the pulverized sand there for tamping, and we have always used it for tamping, and allow no person to use anything else. I have always endeavoured to impress upon the minds of the men, on the survey or before the survey, that if they attempt to use anything else and any accident happens they shall have nothing from the mine. I believe we went on for seven years, and never had an accident, after introducing this sand, and at the same time I introduced oak sticks, about two feet long, made of dry oak, and I requested that they would tamp the powder with them instead of with the bars. We went on for, I should think, seven years and never had a single accident. A man who had just come in, out of stupidity or, perhaps, laziness, I do not know which, had taken up some stuff from the bottom of the level and it exploded. He had but one eye and he lost that.

7528. You think that if they used this proper tamping sand there would be no danger of igniting the powder?—If they use that proper tamping sand and the oak stick there is not the slightest danger. I am satisfied about that.

7529. But the tamping sand alone without the oak stick would not be safe? — I should use the oak stick in preference to everything. I say it is sufficient for everything except, it may be, for a particularly hard drawing hole, and I do not know that it would not be sufficient there.

7530. Do the men in Botallack mine use the oak stick?—Always. We charge them nothing for it, and if we found them charging a hole without it they would be dismissed.

7530 *a.* Have any of the men made objection to using the oak stick?—Not one. It is only from carelessness that they will get something else.

7531. I suppose the advantage of an oak stick is that the iron may strike against the rock and a spark go through the tamping, or there may be loose powder about the hole?—Yes; I think that one reason why holes explode very frequently is from there being loose powder about the hole.

7532. If you had any tamping-rod which would not strike fire against the rock would it not be as good as the oak stick?—Yes; but if the oak stick is sufficient I do not think there is any reason to risk anything.

7533. Then it is your impression that a man can complete the tamping with an oak stick?—He can complete the bottom part of it with an oak stick; for the remaining part, perhaps, it would be better to have it driven a little tighter, but I think that an oak stick is sufficient for the hole.

7534. You think that in all mines provision should be made to prevent, if possible, accident by the use either of an oak stick or some other tamping-rod which will not strike fire?—Yes, I should recommend it by all means.

7535. Do the men ever use cartridges?—Yes, occasionally in a wet place, but not elsewhere.

7536. You have never known the use of cartridges to be general in a mine?—No; the powder which we have from Kennell is very large.

7537. (*Mr. Holland.*) Is it as large as coffee berries?—No, hardly, I should think. Some of it is very nearly as large as coffee berries, but I think that that is rather an excess; it is like peas just broken in two, and whole peas, and so on. Scarcely any of it will stick about the hole, but if you have very fine powder it will stick about the hole. We think that our powder is better for that reason.

7538. That very large grain powder, I suppose, hardly wants cartridges?—No, except it is in a very wet place. Our powder is I should say, generally larger than split peas

7539. (*Mr. Kendall.*) What are the average wages of your men at tut-work and at tribute? — I should think somewhere about 3*l.* 5*s.* a month.

7540. What are the wages for the girls?—A shilling a day for the girls in the copper floors.

7541. And the boys begin at ten years of age?—Yes, and so go on.

7542. What is the lowest sum, 3*d.* a day?—I should

think that there are none under 7*s.* or 10*s.* a month. The underground boys get more.

7543. From ten to sixteen years of age you go up to what amount, from 10*s.* ?—Up to 20*s.* or 25*s.*

7544. Do the young men marry early ?—Very many of them do, rather too early.

7545. What do you call early ?—Many of them marry before they are twenty, and I think that a little too early.

7546. When they marry, do they at once go into furnished houses or into lodgings ?—I think they go into their own houses principally ; there are no such things here as furnished lodgings.

7547. Generally speaking, are they provident or improvident in their marriages ?—There are both sides—there are some who are very provident indeed; others, I believe, are equally reckless, but I think that the latter are the fewer number.

7548. On the whole, you think that they are fairly provident ?—The greater number of them.

7549. You have spoken of men having lost their lives under ground—are they, as a class, reckless about life, from your experience. Your experience is very great amongst them, is it not ?—I have had pretty long practice among them. I think that the young men are considerably more reckless than the elder ones and you will find that all the blind cases around the parish have been occasioned by young reckless fellows. It is a very rare thing to hear of a steady elderly man meeting with a misfortune.

7550. Taking the young as a body, at present, and the young as a body when you can first recollect, are they improved as far as their care goes in their working underground, and in the use of powder or not ?—I do not think that they are very much improved, I am afraid not.

7551. You have been asked with respect to the draught the moment you hole a winze, is it not the fact that the moment you hole a winze circulation begins ?—Yes, most certainly.

7552. Within a minute ?—Yes, except you have some very small hole which would not have the effect.

7553. Although the circulation may vary according to the wind, and although the draught may on one day go up and on another day go down, still at the same time, is there not a general circulation ?—Yes, there is sure to be, if you take the means to do it ?

7554. The foul air does not remain in the mine, it gets out somehow ?—Yes, most certainly.

7555. There is an idea that as there is not a regular up-cast and down-cast, and as there is a variation, it is not only very possible but very probable, that, instead of getting your foul air out of your mine you have this foul air working round in your mine for a very long time, and that there it remains, is that your opinion ?—I do not believe anything of it ; where you have two or three shafts, 50 or 100 fathoms apart, the air goes down one and up the other, and the next day it goes down the other and goes up the first one and takes every thing with it.

7556. Although there may be a variation in the mode of circulation, yet your idea is that there is sufficient ventilation to take the foul air out in a short space of time ?—Yes, most certainly. You will sometimes find it in such a state that you can hardly see the candle.

7557. With regard to the club-money, as I understand, you at one time kept a separate account of your club-money, and you found, after a certain time, that the account went against the adventurers and you dropped the separate account ?—Yes.

7558. As there are less accidents now, do you believe, as far as you can judge, that if you kept a fair debtor and creditor account now it would be in favour of the adventurers ?—I think that there would be very little balance either side. If I had thought of it I would have brought the cost-book and you would have seen the column for the club and the column for the doctor ; they very nearly balance.

7559. (*Mr. Davey.*) A question has been put to you by Lord Kinnaird and by Mr. Kendall afterwards, which has not been answered. You say that when you hole a winze you have an immediate communication from one end to the other ?—No ; I did not say that from holeing a winze you would have immediate communication from one end to the other.

7560. From one winze to another there would be a draught ?—Yes.

7561. Supposing an end to be 10 fathoms beyond that winze, what would be the result ?—It would depend upon circumstances. You cannot always answer that question, neither is the thing always the same, I think.

7562. How would you throw the air in, 10 fathoms beyond a winze ?—You would either throw it in with a soller or put in a pipe and a fan if the air had got close ; but you can drive a level from some winzes for 50 fathoms.

7563. If you have communication every 10 fathoms the air goes down one winze and up another ?—Yes ; but if I have two or three winzes down, I shall cover over all the after ones and carry in a soller. The winze would be covered up, and the air would be sent on.

7564. You have stated that all your levels are worked single handed ?—Principally so.

7565. And that the men are not away from the surface above seven hours, and are not working above five hours ?—I do not think they are.

7566. Consequently, your levels must be 19 hours out of the 24 unoccupied ?—I should think that for 18 hours out of the 24 they are unoccupied altogether as an average.

7567. Therefore, you would not consider so much air to be consumed as if the levels were longer worked in ?—Most certainly not. We would work ours harder in some places if we could, but the men will not go. They will not go and work in the afternoon, and a good many of them are so very independent that they will not work on a Saturday.

7568. Do you think that the reason why you cannot get men from other parishes is, because they cannot work single handed ?—Yes ; and they cannot live at the same price that we pay ours. They cannot get so much money.

7569. You say that the average gettings of your men are about 3*l.* 5*s.* a month ?—Yes ; our wages were over that amount on the last pay.

7570. That is beyond what they get in the midland part of the county ?—I am sure it is, Tut work and tribute work are very much the same, sometimes they vary ; sometimes one will do better than the other either way, but taking them as a whole I think the average is what I have stated.

7571. What price ground do you get ?—In Huel Cock the ground is hard, 6*l.*, 7*l.*, 8*l.*, and 9*l.* a fathom. In the Crowns, it is not so hard ; it is perhaps 4*l.* or 5*l.* a fathom. In Chicornish I think that one man and boy broke 13 fathoms last month.

7572. What sized borers do you generally use for one man?—Seven-eighths.

7573. That would be somewhat smaller than what two men would use ?—Two men would use a 1-inch borer, I suppose ; a great many of ours are not more than three-fourths ; they are all cast-steel.

7574. You mentioned that using sand in tamping was a great safety for blasting the hole ?—Yes.

7575. How do you use sand in tamping ?—We put it in for tamping the same as anything else.

7576. What do you put with it ?—Nothing.

7577. Can you tamp with dry sand ?—It will get damp ; it is not the slime.

7578. Are you aware what is the temperature of your levels ?—No ; not of late, but we have not a complaint about a single place in the mine that I am aware of.

7579. It is not very hot ?—No, it is nothing like what it was.

7580. I have heard of people in this country who prefer working in a warm place to working in a cold

St. Just.

Mr. S. H. James.

1 August 1862.

one ?—There are some people who have been accustomed to it, who have been working in a warm place who, if they go into a cold one, suffer at once. I knew one man that we had who had been working in the 180 fathom level not less than 10 years, and when he left us, he was as fine and healthy a looking man as could be ; he went away to another mine and got cold, and has not been so well ever since.

7581. How many doors or enclosures have you to your winzes ; have you many ?—Not many ; perhaps one here and another there. It is wherever the air is wanted.

7582. Is the door taken away afterwards ?—It is thrown open when it is not wanted.

7583. Is it removed ?—No, not generally, because you want it occasionally.

7584. Would a soller be of any use leading from a winze where the draught was upwards ?—Yes, you might turn it in any way by covering over the winze.

7585. But not without covering the winze ?—No, because the air would escape to the first place—that is natural.

7586. You say that the foul air finds its way out of the mine, how long do you suppose from your lowest level the foul air would be finding its way out of the mine ?—A very short time indeed, I should say.

7587. Have you ever made any experiment ?—No, we have never been called upon. It will depend upon circumstances. In the lower part of the mine, if the wind shifts and gets over the land, and is very light, you will find that the air will be close down in the mine, whereas, if it gets out to the southward or west or north-west, it is otherwise.

7588. In that case, will it take one hour to get out ?—I should say not half the time ; but when the wind is not so favourable, the air is not so good. At least it was the case. I do not think there is anything of it now. I have heard some of our people say that they were very glad to have a great coat to get into a corner to smoke their pipe.

7589. On pay-day do you pay in notes or in gold mostly ?—We pay about one half in cash and the other in notes.

7590. Where do they get the notes changed ?—Anywhere ; any person will change them here at any shop or market, or any where, if they want to buy anything. I brought home 1,275*l.* with me last night to pay tomorrow.

7591. Do they change the notes at the public-house ?—At the public-house, or at the shop, or anywhere.

7592. How are the doctors appointed in your mine ?—By the adventurers.

7593. (*Mr. Kendall.*) From your experience, where do you think that these 5*l.* notes are mostly changed ? is it or is it not at the public-house ?—That is a question which I cannot answer.

7594. (*Mr. Holland.*) Are they obliged to go to the public-house for change ?—No ; I do not think that the notes are principally changed at the public-house. Some people will go to the public-house to change them, and if they had not a necessity for it they would make some excuse to go there.

7595. (*Mr. Kendall,*) Your idea is, that whether they had notes to change or not they would go to the public-house ?—Yes.

7596. From your experience, is it not a fact that in order to induce men to come to their public-houses, the publicans get a large quantity of small change in order to accomodate the miners, so that they may split up the larger sums of money paid to them by the purser ?—I should think that there is something of that sort still carried on. I think that the shops and public-houses are prepared to receive the 5*l.* notes, and to give them their change if they come to pay their accounts ; but I think that there is very little credit at the public-houses with us.

7597. (*Chairman.*) Is there much credit at the shops here ?—I am afraid there is too much credit at the shops.

7598. Can you account for that ?—I suppose that the hope of reward sweetens labour. I suppose that they hope to profit by it.

7599. If the men were paid oftener, would it not prevent that to some extent ?—No, I think not ; once a month is often enough to pay people.

7600. But a man coming to you from another part of the county would not receive any payment for two months ?—Yes he would, if he came to me and wanted money.

7601. But according to the rules, he would not be entitled to get any money for two months ?—No ; but then we should grant him subsist.

7602. But if you did not grant him subsist it would induce his getting into debt at a shop ?—It would.

7603. (*Mr. Holland.*) As a matter of practice, subsist is given, is it not ?—Yes ; we give subsist every pay.

7604. And before every pay ?—No ; our subsist to-morrow would be perhaps 40*l.* or 50*l.* to people who think that they want something.

7605. Tributors whose accounts are good ?—Yes ; and those whose accounts are not so very good perhaps. If they were good men we should subsist them at once. Our list of subsist is made out now, and the pay is made out. The setting will begin at two o'clock exactly, and as I begin the setting the clerk and surface agent begin the pay, and in an hour or an hour and a half the setting and pay is all over ; every man is paid and has gone about his business by about three o'clock or a little after.

The witness withdrew.

Mr. Richard Burford Searle examined.

Mr. R. B. Searle.

7606. (*Chairman.*) What mines are you connected with ?—Balleswidden, Boscean, and Huel Caw.

7607. How long have you been surgeon to these mines ?—Eight and a half years.

7608. Were you in any other district before you were surgeon to these mines ?—In no mining district.

7609. Have you at all turned your attention to what is called miners' disease ?—Yes ; a number of miners come under my care in our mines and neighbouring mines.

7610. Do miners from neighbouring mines, as well as from these mines, come under your care ?—Yes.

7611. So that you may say that you have had good experience in this disease ?—Yes.

7612. How many at the present time have you off work from diseases of the chest ?—I cannot say. There is not a large number by any means. I know that there is one man who I think is about 60 years of age ; he is laid up with an affection of the chest. I think it is nearly 20 years since he went underground ; the symptoms frequently lie dormant for a long time.

7613. Have you any men now working underground who have been to you and have gone back again ?—Yes ; numbers who are permanently short breathed are now working.

7614. Can you furnish us with the names of a few of those men who are permanently affected ?—Yes, by just recollecting ; I could tell the names on a future occasion.

7615. By what cause do you think that this is occasioned ?—By a local irritation, not constitutional disorder like phthisis, it is vastly different. The pulse of miners' decline is frequently short, frequently shorter than natural. This statement would apply solely to the first stage or period of irritation and spasm ; the heart's action not only becomes depressed in tone, but its frequency affected, frequently intermitting, either due to reflex action or deficient anterialization of the blood, probably a combination of both. In phthisis it is a quick pulse.

7616. In your opinion, by what is this occasioned ?—By irritating matter lodging in the air cells.

7617. Is that matter which is drawn into the lungs

while working in the mine?—Yes; unconsumed carbon.

7618. Anything else?—Not that I am aware of. It is very black. I have seen a man after an attack of inflammation spit up the best part of a quart of black matter in the course of 24 hours.

7619. (*Mr. Holland.*) Do you mean phlegm blackened?—Phlegm made dark with black matter.

7620. (*Chairman.*) How long after he had been up from the mine did you observe this?—I think that that man had not been working underground for 10 years; the matter had been lying there all that time until an attack of inflammation ensued, and then you got it loosened and thrown off. I was struck with the large quantity thrown up. That man is dead now.

7621. Was this matter ever examined by a microscope?—No.

7622. You could not furnish us with the name of any man with whom that is likely to be the case now?—No. I have a case now where a man has not been working underground for 20 years, and yet he spits up black matter, but not the same quantity.

7623. The man who you say is 60 years old, and has not worked underground for 20 years, still occasionally spits up black stuff?—Yes.

7624. (*Mr. Kendall.*) Does he smoke much?—I am not aware that he does. I have not seen him smoke.

7625. (*Chairman.*) Do you think that the effects upon the miners arise from the carbon and not from the air or from climbing the ladder?—Yes; I believe that they arise from the carbon. The men get contraction of the air passages, and they are in a state of chronic asthma, they are asthmatic. If you sound a man's chest, you get a clearer sound on percussion than is natural certainly in the first stages; in the last and third stage, when ulceration has taken place and the air cells become filled with purulent matter; as also in the second stage, when there is permanent contraction of the bronchi from thickening, the sounds or percussion are proportionably dull, which is quite the reverse of phthisis.

7626. Do you think that these men are at all affected by the ladders?—The ladder affects them by telling on the heart.

7627. A man affected in this way would feel the ladders more than a man in sound health?—Yes; no doubt.

7628. (*Mr. Holland.*) Do you think that miners are under-fed as a rule?—I believe that their food is not the best calculated for them; miners are a great deal subject to indigestion.

7629. Are a large proportion of them suffering from indigestion?—Yes.

7630. In what part of the country did you practice before you came here?—I am a native of Dorset. I have been in Hampshire. I only practised a few months in Hampshire before I came here.

7631. Did you serve your apprenticeship in Dorsetshire?—Yes, in Bridport.

7632. Do a larger proportion of the miners suffer from indigestion than the inhabitants of Dorsetshire?—Yes; I think they do.

7633. Decidedly larger?—Yes; I think so.

7634. Do a larger proportion suffer from rheumatism?—No.

7635. Is there any excess of disease among the children?—Yes; 50 per cent. of the deaths in this parish, I believe, are of children under three years of age.

7636. Are you well assured of that?—I was looking over my list to-day, and I came to that conclusion. It is remarkable how the children die off here.

7637. (*Chairman.*) Is that conclusion drawn from the register, or from your own observation?—From my own observation.

7638. (*Mr. Holland.*) What are your data for that conclusion?—If you take 100 deaths, you find that 50 of them are under the age of three years.

7639. Do you know the number of births in the parish?—I think that there are about 400 in the year.

7640. Do you know the number of deaths under three years of age in the year?—I do not.

7641. To what do you attribute the great mortality of young children?—The great majority of them die in what we call a state of marasmus, a gradual sinking away of the body; and a great number die of croup, which you may say is endemic to St. Just; scarcely three or six months pass over without having croup here; it is very seldom absent here, croup and typhoid fever.

7642. To what do you attribute that?—To the damp atmosphere and the deficient drainage.

7643. (*Mr. Kendall.*) Do you find croup as rife among the agriculturists as you do among the miners?—Yes; I find croup in the outlying districts.

7644. As far as the miners are concerned, the croup is not more prevalent here than among other parties?—The mining population are much in the majority here; there are very few who pay attention to agriculture.

7645. As far as your experience goes, do the children of the miners die more under three years of age than the children of the agriculturists?—Yes; most decidedly.

7646. To what do you attribute that? Why should a miner's child be more subject to die under three years of age than the child of an agriculturist?—Because the father is generally is in a more infirm state of health. The state of health of the miner tells upon the offspring decidedly.

7647. Am I to understand you that the miner is not so strong a man as the agriculturist, and that his occupation, not being so healthy an occupation, what affects him affects the child?—Yes.

7648. How long have you been practising in this neighbourhood?—Eight and a half years.

7649. Did you commence here as a practitioner?—Yes, I may say so. I was only a few months in Hampshire previously to coming here.

7650. What age are you now?—Thirty.

7651. You began practice at what age?—At 21.

7652. What is the earliest age at which you can begin, according to the laws of your profession?—Twenty-one.

7653. And you began as soon as you could begin?—Yes; I was the first man in our college of my year who took out the double qualifications; so that I did not lose any time. I came here as an assistant to a mine surgeon first. It is generally the rule here to nominate the surgeons to the mine. The mine surgeon frequently lives out of the place, and he gets some one to fill his place for him; that is done in many cases by unqualified men.

7654. (*Mr. Holland.*) You mean not legally qualified?—Not legally qualified.

7655. (*Mr. Kendall.*) Generally speaking, as I understand you, or very frequently this is done, and as the adventurers have the appointment of surgeons, some men get appointed who live at a distance?—Yes.

7656. And they supply their places by unqualified men?—Yes. I may say that I am a miners' surgeon, but not a mine surgeon.

7657. You had taken your proper degrees in London?—Yes.

7658. And you came down here with a full degree, and took the place of a party who was residing at Penzance?—It is rather a strange circumstance about my staying here. I was about leaving the place, and the men of the mine that I attended to struck, and brought me back again; and they said that they had never been so well served before, and wished me to serve them.

7659. (*Mr. Davey.*) Are you appointed directly by the adventurers, or are you a surgeon substituted for another?—The men themselves took it out of the adventurers' hands, and chose me as their surgeon.

7660. (*Mr. Holland.*) I understand you to attri-

St. Just.
Mr. R. B. Searle.
1 August 1862.

bute this marasmus of children to the broken health of their fathers to a great degree ?—Yes.

7661. Have you noticed that the younger children of a family have been more liable to marasmus than the elder children ?—I have not noticed that.

7662. At what age do miners generally become broken in health ?—It varies from 45 up to 55.

7663. They are but little broken in health before 40 ?—They are weazened for years before they get laid up.

7664. They do not begin to break in health until after 35 do they?—No ; it is very seldom that you find a man much affected in breath before 35.

7665. And not very materially until after 40 ?—No.

7666. These men marry early, at 20 or thereabouts, do they not ?—Yes.

7667. Are not a large proportion of their children born before their health becomes broken ?—Yes.

7668. And yet the health of those children is not materially different from the health of the children born after that ?—No.

7669. How, then, can the ill health of the children be attributed to their fathers' broken health ?—I suppose they are not in good health from their boyhood ; they are not so healthy as boys as agriculturists, even those who survive infancy. Many commence working underground at 9 or 10 years of age.

7670. (*Chairman.*) Have you anything else which you wish to state ?—As regards death, I have met with one case of death here by poisoning from arsenic.

7671. Have you met with any case of death from any infection taken internally from the mine ?—Yes, from dressing the tin ore ; either from the metal itself containing arsenic, or from the hydro-chloric acid containing arsenic.

7672. (*Mr. Holland.*) How did it affect the man ?—He was taken with convulsions.

7673. Are convulsions a common symptom of arsenical poisoning ?—I cannot say that they are, but it is only one case that I have met with.

7674. Did you ever hear of convulsions as a common symptom of poisoning by arsenic ?—Yes, accompanied with salivation and vomiting.

7675. (*Chairman.*) About how long ago is this case to which you refer ?—I think that it was between two and three years ago.

7676. Did you ascertain this by *post mortem* examination or otherwise ?—No, but I concluded that the symptoms were brought on by that, and I I thought that it was carried out by the man's occupation.

7677. You never met with any other case of the kind ?—No.

7678. (*Mr. Davey.*) What age was the man ?—I think that he was about 26.

7679. Do you know in what portion of the tin-dressing he was occupied ?—It is cleaning the ore by hydro-chloric acid ; I do not know what occupation they call it.

7680. Was it after the ores were calcined or before ?—I do not think that the ore is calcined there, it is considered pure enough to do without calcining. I think that they dress it with hydro-chloric acid and that that is sufficient.

7681. (*Chairman.*) What are the usual symptoms of poisoning by arsenic ?—Irritation of the stomach and intestines.

7682. (*Mr. Kendall.*) Was this not during calcining, but merely in dressing the pure ore ?—Yes; I do not think that they roast the ore in this mine.

7683. Do you fancy that in dressing the ore there is an escape of this arsenic ?—Yes. They dress the ore with hydro-chloric acid which is supposed to clear the ore from arsenic I believe (so I have been given to understand), and either from the ore containing arsenic or the acid itself containing arsenic I suppose the man was affected thereby.

7684. Do you think that the arsenic would escape from the simple dressing of the tin ore in the open air ?—The arsenic would be set free by the hydro-chloric acid.

7685. (*Mr. Holland.*) Would it become gaseous ?—Yes, in the form of arseniuretted hydrogen.

7686. And the man would breathe it ?—Yes. The men frequently cannot stand it above a short space of time, they have to go into the open air from the irritation produced by dressing the ore.

7687. (*Chairman.*) In what mine was that ?—Huel Owles mine. I do not belong there.

7688. Is that process carried on now ?—Yes.

7689. (*Mr. Kendall.*) In order to get rid of the arsenic ?—I believe so, to clean the ore.

7690. (*Chairman.*) Have you ever seen the men affected by the poison in any way besides that ?—No.

The witness withdrew.

Captain James Bennetts examined.

Capt. J. Bennetts.

7691. (*Chairman.*) Of what mine have you charge ?—Spearne Moor and North Levant.

7692. Are those tin or copper mines ?—Principally tin but a little copper.

7693. How many men have you employed underground in the first-mentioned mine ?—I suppose in the Spearne Moor we have about 65 or 70 men and boys underground.

7694. And in the other how many ?—About 50.

7695. What is the deepest level in each of those mines ?—The bottom of the shaft in the Spearne Moor is 135 fathoms.

7696. And in the other, what is it ?—74 fathoms.

7697. Are those below the adit ?—No, those are from the surface.

7698. How do the men ascend and descend ?—By the ladders.

7699. Are there any ends which are hot or close now working ?—No ; we put winzes through from one level to the other to ventilate the mine.

7700. At present there is no end at all close ?—No.

7701. Have you had any close ends before the winzes were put in ?—Never; I never saw a close end in the Spearne Moor in my life.

7702. Or in the other mine ?—No.

7703. Then you have never had to use any artificial means ?—We have in North Levant but never in the Spearne Moor. In the North Levant we have had to force air into one end by a fall of water, but the air was very pure in the end when it was forced there by water.

7704. But not before ?—Not before. The men could work there and keep the light very comfortably, but we thought it our duty to put as good air there as we possibly could.

7705. Did the candles always burn upright ?—Yes, as much as half a dozen at the same time.

7706. And yet you thought the air was not so good as it ought to be ?—Yes, we found it out by blasting; when the holes were blasted the smoke would remain a good while and by putting this air in the smoke would be driven out quickly.

7707. Before you put in the air how long did the smoke remain ?—I suppose that it remained for two hours before it got altogether out.

7708. But the men would get in to work before that ?—Yes.

7709. After you put in the water how long was the smoke getting away ?—The smoke would go away very quickly. I should say that it would all leave the place in half-an-hour.

7710. (*Mr. Holland.*) In one quarter of the time ?—Yes.

7711. (*Mr. Kendall.*) Did you put in the air by the water machine for the sake of the men or for the sake

of getting the smoke out ?—For the sake of the men; getting the bad air out of the place would be for the benefit of the workers.

7712. (*Chairman.*) You did it for the sake of the men, both for their health and for their being able to work more ?—Yes.

7713. Can you describe the fall of water; how it managed to give this supply of air ?—The fall of water is 18 fathoms; it falls and there is a pipe leading off from a cistern; the water falls into a cistern and it forces the air into iron pipes, and when it enters the pipes there is no other way for the air to escape until it goes to the end. The water rises to the top of the cistern and runs over, and the air is forced into the pipe, and there is no way for the air to escape but to the end of the pipe where the men are working.

7714. And you found that that gave complete relief ?—Yes; the launder is four inches square, the pipe is sometimes nearly full of water.

7715. The air is carried by a pipe to the end ?—Yes.

7716. How far have you ever carried it ?—We have worked, I suppose, about 90 fathoms.

7717. With a pipe for air 90 fathoms from the fall of water ?—Yes.

7718. Before you put that in were the men at all affected ?—No.

7719. Have you any men working in these mines whose breathing is at all affected from having worked in any other mines ?—We have one working in North Levant who worked very hard in other mines, and he is affected; he is the only one that we have in the two mines.

7720. What is his name ?—John Stevens.

7721. Where does he live ?—In Morvah.

7722. How old is he ?—I suppose about 40; but he never received any injury in North Levant by the impurity of the air.

7723. You think that the affection was before he came there ?—Ever since he has been working in North Levant he has been working where the air was very good.

7724. What amount of candles are the men allowed; how many lbs. a week ?—They are allowed about 2 lbs. each.

7725. What do they pay for them ?—They pay 8*d.* a lb.

7726. What kind of candles are they ?—They are very good candles. I do not know what name to give them.

7727. Are the candles from London ?—We have our candles from Mr. Higgs at Penzance.

7728. What is the price of them per lb. wholesale, as you get them ?—About 6*s.* 6*d.* or 6*s.* 9*d.* a dozen now, I think.

7729. Do you use any particular kind of powder ?—We use the Kennell powder—the old powder; we have introduced none of the new powder which has been lately made.

7730. Have you tried any of the new powder ?—No.

7731. What price do the men pay for the powder ?—8*d.* a lb.

7732. What is the cost price wholesale ?—50*l.* a ton.

7733. How much is the doctor's fee that the men have to pay ?—6*d.* a man per month.

7734. Is there any barber ?—No.

7735. How much is the club-money ?—6*d.* per month.

7736. Is that accident club-money ?—Yes.

7737. Only for accidents ?—For accidents, and occasionally sickness.

7738. There is no provision for the men in sickness ?—Not in the mine; some have clubs among themselves.

7739. Is there a separate account kept of the club-money ?—That is generally left in the purser's hands; the purser generally manages that with the agents.

7740. You cannot speak to the management of the club-money ?—No; I think that the account of it is kept separate from the mine account.

7741. Do others, besides the men who work underground, pay to the club-money ?—Yes; but then they are left to have their own way; they can either pay or leave it alone.

7742. But there is a regular deduction for the men working underground ?—Yes, and some men who work on the surface as well.

7743. Have there been any accidents at either of those mines since you have been there ?—One in each. A man blasted a hole in the 110 fathoms level at the Spearne Moor, about a year and a half ago; the level was straight, and he fancied that he was out of reach, and a stone struck him in the back, and he died from it. In the case of a man in the North Levant, a hole exploded about him, and he lost his eyes by means of it.

7744. What was he tamping with ?—With sand that we get from Balleswidden mine, the safest that we can get in the district; we keep a stock in the mine for the purpose, and wooden chargers for them to put the powder in with.

7745. Do you use cartridges at all ?—No; our mine is dry.

7746. How do you think that the accident happened ?—I suppose that it was through neglect in putting the powder in, and that the man used iron instead of wood. They try to make all the excuses they can when an accident does happen, but we provide everything that is necessary to prevent accidents.

7747. You provide a wooden tamping rod ?—Yes.

7748. Do you think that sufficient to complete the whole operation ?—They generally put in a part with it, and the remainder with the iron.

7749. If there was any powder about, the iron rod might strike a light, and it might ignite below the tamping ?—Yes; and it might cut the fuse.

7750. But if it cut the fuse, would it not take a longer time before it went off ?—Yes, I suppose it would; but I do not think any one can account for how the holes fire sometimes.

7751. If you had a rod which would not strike fire would it not ensure safety ?—If there was a grain of powder, and it ignited, it would not go to the bottom. A grain after the hole gets two-thirds filled would not go to the bottom; and there is no way of the hole being fired except through the fuse being cut.

7752. Is there not a good deal of powder mixed up with the tamping ?—No; but powder sometimes sticks to the side of the hole, which is generally cleaned out.

7753. If that was neglected it might cause an accident ?—Yes.

7754. How many men are receiving money from the club ?—Only one in North Levant.

7755. And none in the other mine ?—No; the man in the North Levant receives 30*s.* a month. We pay a widow woman something. A man worked in our mine, and was taken sick, and died of fever; we did not think well of giving the woman money at the same time, but we have been giving her 1*l.* a month since out of the club money. The man worked there a good deal of his time, and we thought that the man worked a little longer than he was able.

7756. Was he ill before ?—He complained some days before he returned from the mine; and we helped the widow a little from the club money.

7757. What is the name of the purser of that mine ?—Mr. Higgs, of Penzance.

7758. He could furnish us with an account of the club money ?—Yes.

7759. Do you pay your men partly in notes and partly in gold ?—Partly in each.

7760. Do you know how the men get the notes changed ?—Sometimes they go to the shop where they have their meat, and the shopkeeper gives them change.

7761. When the taker wants to divide the money between the different men of the corps, how does he get it changed ?—Sometimes they go to the shop-

St. Just.

Capt. J. Bennetts.

1 August 1862.

keeper with whom they deal, and sometimes they come back to the mine again to the purser, and then the purser gives them all the change that he possibly can.

7762. But if he has not got it, will they go to the public-house?—I suppose that some do.

7763. What proportion of notes and gold on your pay day do you pay?—I think that we pay a quarter of our money in notes.

7564. (*Mr. Kendall.*) Not more than that?—I should not think that we did.

7765. (*Chairman.*) How many boilers have you in your mines?—One boiler at each mine.

7766. How often is it cleaned out?—It depends upon the quality of the water that we have. I suppose upon the average once in a year; but then we condense with clear water. If the water was foul, we should clean out the boiler oftener. We have a clear stream of water which runs through the adit level, and that is employed for the purpose of condensing with.

7767. For supplying the boiler?—Yes.

7768. When the boiler is cleaned out is there any accumulation?—No; nothing but the settlement of the water. Sometimes if we have been driven up for clear water we have tried a little foul water and then it leaves a little slime, and that is washed out.

7769. Have you ever heard of any boiler bursting in this neighbourbood?—In the neighbourhood I have; not in any mines with which I have been connected.

7770. Can you tell us any mine where a boiler has burst within the last three years?—I suppose it is not more than three years since there was a boiler explosion at Pendeen; it might be a little more.

7771. Have you a water gauge?—We have taps at the end of the boiler.

7772. And a gauge to show the quantity of water?—No; we have no gauge, but we have one tap over the other, and the lower tap is in the tube of the boiler, and we can tell how high the water is.

7773. Are the men who are employed at the boiler men who were formerly engineers or miners?—One of our men has been to the engines all his time, and the other, I suppose, about 10 years.

7774. (*Mr. Davey.*) Do you understand much about the dressing of tin?—Yes.

7775. Do you use any new patent for cleansing it?—No.

7776. Do you suppose that any arsenic or any other mineral would injure a man from merely washing it?—No; I cannot see how it should.

7777. Are you aware that there are some acids used for dressing tin?—In some mines there are, but not in any mine with which I am connected.

7778. Do you know for what purpose?—I suppose it is to destroy all kinds of ingredients which are mixed with the tin.

7779. Is it for destroying the arsenic or sulphur or copper?—To destroy the copper or anything that may be in it; to make the tin more pure.

7780. You have never been any such acid used yourself?—No.

7781. (*Mr. Holland.*) Do you know how much water the ventilator which you have described consumes?—Not exactly; I could tell in a short time.

7782. Do you know how much air it drives in?—It drives enough air in to blow a candle nearly out. I do not know the quantity of air.

7783. Through what sized tube does it drive it?—A four-inch round tube.

7784. Have you noticed how much it cools the end?—The air is very fresh there. I do not exactly know the quantity of air or of water.

7785. Was the end hot before you put it in?—No.

7786. (*Chairman.*) You have not noticed the difference in temperature created?—No; the air was not very impure before we put the pipes there.

7787. (*Mr. Holland.*) Did you say the draught blows out the smoke about four times as fast as before?—Yes; or the current of air.

7788. (*Mr. Kendall.*) Why do you charge your miners more for the powder which they have of you than you give for it at the merchant's; and why do you charge more also for the candles?—There is an understanding with miners generally, that if they can have candles at a lower rate at the mines than they can from the shops, they will carry candles home from the mine; and it is a check that they shall not be taken away. Generally there is a calculation made of about what the men shall get in a month, and in that respect the price which they are charged does not matter, and it will prevent their taking the candles away.

7789. If you were to let them have them at the same rate as you buy wholesale from the merchant, have you any idea that they would be enabled to sell cheaper than people could elsewhere?—Thousands of pounds of candles have been carried away from the mines and sold by miners, at the present price.

7790. And, therefore, thousands more would be sold if you put a lower price on?—Yes.

7791. (*Chairman.*) What is the price at the shop of a pound of candles?—I suppose about 7*d.*

7792. Then there is 1*d.* difference?—Yes.

7793. I thought you stated that the miners were only allowed 2 lbs.?—They are allowed 2 lbs. a week, but sometimes there are boys working with the men, and the boys may not have much to do; the boys have the same quantity as the men have; and while the under people and boys are not employed working, the candles are put out. Sometimes the men are engaged at the surface spalling their stuff, and then they can accumulate their candles, and sometimes, though rarely, they steal from each other.

7794. (*Mr. Davey.*) Do your men all work single-handed?—Principally; but sometimes when the ground is very hard they work double.

7795. How many hours do you suppose they work?—I suppose that they work eight hours on an average.

7796. Would they require 2 lbs. of candles a week to do that?—No. When there are two working in one place one candle will do for the two, and two good candles will hold nearly six hours.

7797. Therefore, if you allow them 2 lbs. of candles you give them an opportunity of going to a shop to dispose of them?—If they work single, and their lights are continually burning, it will take a great deal of that quantity, and they are continually using little candles at home; they are carrying a few home in the week to burn in their own houses.

7798. But, as you say, a great many find their way to the shops now?—I have not a doubt of it, and where the beer is sold. We never allow more than 2lbs. of candles to go with each man.

The witness withdrew.

Captain JOHN CARTHEW examined.

Capt. J. Carthew.

7799. (*Chairman.*) Of what mine have you charge?—Carnyorth is one, Spearne Consols, and St. Just United.

7800. Will you be kind enough to state what number of men you employ underground in each of those mines?—I should think there are about 70 employed in Carnyorth, in Spearne Consols about 45 underground, and in St. Just United 55.

7801. Do you mean men and boys?—Yes

7802. How many women and children are employed above ground?—In St. Just United the whole number is 156.

7803. And how many at Carnyorth?—At Cranyorth there are about 120 altogether, and in Spearne Consols I should think about 105; in St. Just United 156.

7804. In which of those mines is there the deepest level?—In Spearne Consols.

7805. What is the depth of the deepest level there?—140 fathoms under the adit, 166 fathoms from the surface.

7806. By what means do the men ascend or descend the mine?—By ladders.

7807. In which of these mines is there copper, and in which tin?—Copper and tin in St. Just United, in the other two tin only.

7808. Is it in granite or killas?—Both in St. Just United; the others granite only.

7809. Are there any hot levels in those mines?—Not at all hot. Spearne Consols is the hottest of the three mines.

7810. Do you know what the greatest heat is at any one level?—No; but I do not think the heat is more than our common heat. They are cold mines generally.

7811. Do they not require any artificial ventilation?—None of them; we have no artificial ventilation in any mine that we have got.

7812. How many shafts are there in Spearne Consols?—There are three in Spearne Consols, and in Carnyorth we have three shafts; only two in the south lode, and one in the north lode.

7813. Is the north lode not connected with the south lode?—No; but it is connected with Spearne Consols.

7814. Does the same pumping engine answer for both?—The same pumping engine from Spearne Consols draws the water from the north lode and the other.

7815. In St. Just United, how many shafts are there?—Eight.

7816. Was that an old mine?—Yes, and it is now put on.

7817. How long has it been put on again?—It began in last January.

7818. How long have the other mines been at work?—I have been in Spearne Consols for 22 years, and in Carnyorth we put her on afresh 10 years back.

7819. How long is the powder smoke in clearing away after an explosion in any one of these mines?—Our mines are very well ventilated, and there is no complaint from any man or boy as to the ventilation in either of the mines.

7820. How long is the powder smoke in clearing away?—I cannot pretend to say how long.

7821. Have you ever taken note of the time?—No; but I have never heard any complaint in either one of the mines.

7822. Has no accident occured in either of these mines during the last three months?—Not in the last three months; in the largest of the three mines we had an accident by an explosion; I mean in Spearne Consols.

7823. Was that accident caused by blasting?—Yes.

7824. Have any accidents occurred in either of the other mines?—No.

7825. Did a man lose his life in the case of the accident to which you have referred?—Yes.

7826. Did you ascertain how the accident happened?—Yes, it was in tamping a hole.

7827. Do you know what the man was tamping with?—I do not know what he was tamping with, I do not recollect now.

7828. Do you supply the miners with any particular tamping rods?—We always supply them with a regular fuse, the best fuse, a tap fuse.

7829. Do you supply them with any particular tamping rod?—We supply them always with a copper tamping rod.

7830. Has it a copper end?—Copper is put on to the iron, we always provide copper; we provide hard wood for any hole they wish to tamp with, and copper as well; we tell them particularly never to use iron.

7831. Do you suppose that the man to whom the accident happened had used an iron tamping rod?—I do not know really, I never heard that he had.

7832. Do you suppose that he had gone back to the hole too soon after the explosion?—I cannot recollect the particulars, but there was no complaint made that anything was out of the common way with him.

7833. Was any inquiry made as to the cause of his death?—Only before the coroner; there was no charge brought against any one.

7834. Was there any inquiry before the coroner as to how the accident happened?—The underground agent of the mine told me that every precaution was taken, and there was no charge against any one.

7835. Did the coroner not inquire as to how the death was caused?—I was not at the inquest.

7836. In the case of an accident of that kind occurring, does the coroner inquire into how the accident happened?—Yes, he always does, whenever I have been present.

7837. Did you ever hear of any agent of a mine being blamed by the coroner?—I do not know; I never look into these things.

7838. You do not know perhaps what was the verdict of the jury?—No, not now; only I believe it was considered on all hands that there was no blame to be attached to anyone whatever; his own brother was with him.

7839. Upon a coroner's inquest taking place, who are the parties called upon to serve as jurors?—I do not know; I was not there; I was not in the habit of going to that mine—not more than once a week.

7840. Generally speaking, who are called upon to serve as jurors?—They call upon almost any person they can find at leisure; any respectable person they can meet with.

7841. Have you ever served on a coroner's jury?—Only once.

7842. What do the miners pay for candles?—*9d.* a pound.

7843. How much do they pay for powder?—*9d.* a pound also.

7844. What quantity of candles is allowed to them?—2lbs. a man per week.

7845. Do you never allow them any more?—No.

7846. If they require more, what do they do?—I do not know; I do not hear any particulars about that; the regular supply is 2lbs. a man.

7847. Could they not get any more if they wanted them?—If they were working in cores they could get some more I dare say; if I found men that wanted more, and they were working long, I should not hesitate to give them a few more.

7848. Do you think the men sell them?—No doubt some of them do.

7849. What do the candles cost you per pound?—They cost us 6*s.* per dozen pounds, and we put an extra price upon that; we consider that the men shall be bound to use them; that they shall not sell them, or carry them home, and we make them pay 9*d.* a pound.

7850. But if they do sell them and pay you all the same, you do not lose, nor the adventurers?—Not at all; we profit by it.

7851. The more they sell them the more profit you make?—Yes; but we do not think anything about that.

7852. Could you furnish the Commission with an account of the quantity of candles consumed in your mine, and the cost of them?—I have no objection to send you anything I can; but I am now come on a sudden.

The witness withdrew.

Adjourned to St. Ives To-morrow at 12 o'clock.

REFORM CLUB PALL MALL

St. IVES.

Saturday, 2nd August, 1862.

PRESENT:

The Right Honourable Lord KINNAIRD, K.T.
NICHOLAS KENDALL, Esq., M.P.
JOHN ST. AUBYN, Esq., M.P.
RICHARD DAVEY, Esq., M.P.
P. H. HOLLAND, Esq.

The Right Honourable Lord KINNAIRD, K.T., in the Chair.

Mr. SAMUEL HIGGS, of Penzance, examined.

ST. IVES. — *Mr. S. Higgs.* — 2 August 1862.

7853. (*Chairman.*) Will you state the mines of which you are purser and superintendent?—The Providence mines, Huel Margery, and Spearne Moor, at St. Just, and my firm, three others, Trelyon Consols, North Levant, and East Margaret.

7854. You have considerable experience in the management of mines?—I have been engaged more than 30 years as the purser and superintendent of mines.

7855. To each of these mines are there a set of rules which are printed and stuck up at the mine?—Yes.

7856. And it is according to those rules that the settings are made?—Yes.

7857. Have you a list of rules with you?—Yes (*producing the same*). These are the printed rules, they just apply to all our mines, they vary as to the amount paid for the club.

7858. It is according to those rules as stuck up that the engagement is made for the work to be done during the following month?—Yes, our settings are monthly; the rules are stuck up at the mine, and they are exposed.

7859. Though the settlings are monthly, there is always a month in hand of the pay, is there not?—Yes.

7860. Will you state why there is always a month in hand?—We cannot measure the work and make up the cost in much less than a month; we might do it on tut bargains in a fortnight, or perhaps less, but it takes a month for the tribute; we do not like to have more public days in the mine than is necessary; one day is enough for setting and paying.

7861. That is a day of cessation from work generally?—Yes.

7862. And if it is on the Saturday, is the Monday following also a day on which no work is done?—We always pay on the Friday afternoons, and every Monday is alike in our mines.

7863. But in many mines they pay on the Saturday?—Yes, and then the Monday is allowed as a broken day.

7864. Is Saturday a broken day in consequence of the payment?—We lose a half-day; Saturday afternoon is always a holiday with the miners.

7865. In all mines?—I believe in all mines.

7866. If the pay is on the Friday, do the men go to work on Monday morning?—Every man is in his place on Monday morning; every Monday is alike in all our mines.

7867. From your experience in the management of mines, do you think that that plan is a good one?—Yes.

7868. Do the men like it?—They do like it; they prefer it, but some two or three years ago there was a feeling against it in some of the St. Just mines, because they would have it that they should be all alike. I am of opinion that mines in the same district ought to be paid on different days in the week, and not all on a Saturday, or all on a Friday.

7869. You are of opinion that the settling days should vary at different mines?—Yes, I think that i would be an improvement.

7870. Will you state your reason for that?—The men would not have an opportunity of congregating together so much.

7871. What you propose might be an advantage to the men, as thus, a man seeking for work in another mine would have an opportunity of visiting it better?—Yes, I think that it would be an improvement for the men. I think that it would be an advantage both to the employer and to the employed.

7872. With respect to the list of rules, are the prices at which the materials are to be supplied to the men mentioned in the rules?—No, the price is fixed according to the circumstances, it very seldom varies.

7873. Is the quantity allowed mentioned in the rules?—No.

7874. That is an understood thing?—That is an understood thing at the mine.

7875. What quantity of candles, for instance, is allowed?—2lbs. a week generally is allowed, I think; for a pair of men 4lbs., but in most of our mines we allow 3lbs. only, we supply them with the best candles and a less quantity will do.

7876. With a better kind of candle a less quantity does?—Yes.

7877. What price are the men charged for those candles which you supply?—I think that they are charged 8*d.* a pound for them.

7878. What is the wholesale price?—The present price is 5*s.* 9*d.* dozen, but that varies; last year soon after this time they were 6*s.* 9*d.*; they average about 6*s.* a dozen, but we do not vary the price to the men, we keep it steady.

7879. What is the reason why the men are charged more than they cost?—I suppose the object is to make the men more careful of them; but the object is defeated, the men care very little about how much or how little they take out, I think.

7880. They are not allowed more than a certain quantity?—No.

7881. With regard to powder, have you any particular kind of powder with which the men are supplied?—They are supplied with the rough kennel powder.

7882. What is the price at which that is supplied?—I think that that is charged 8*d.* or 9*d.* I do not know, I do not look into those things; I have an auditor who examines all these accounts.

7883. But the prices do not vary?—The prices do nat vary unless there is a very great change in the value.

7884. Can you state the amount which is deducted for the doctor's fee?—In one of our mines we deduct fourpence in the pound for doctor and club.

7885. Which mine is that?—That is in the Providence mine.

7886. You deduct fourpence in the pound from what men earn?—Yes, from the balance which they receive.

7887. (*Mr. Holland.*) What does that amount to?—It amounts to about 1*s.* The average of each man's gettings is about 3*l.* a month, but then all who get 1*l* a month and upwards are charged with the club and doctor; that includes both, it is equally divided.

7888. (*Chairman.*) Is there a separate account kept of the two sums?—Yes.

7889. Is that taken from the surface men as well as the under-ground men?—Yes.

7890. The parties who do not earn 1*l.* are not charged?—They are not charged with the doctor or club.

7891. Is it only for visible hurts, or for sickness as

well ?—We have a rule in our mine that the purser and agents may grant relief, if in their opinion the funds of the club will admit to any man who may fall sick from long labour in the mines, or from any casualty; we have that in our printed rules.

7892. (*Mr. Holland.*) That is a discretional payment ?—Yes.

7893. (*Chairman.*) Is the balance of the club account made up every month ?—Yes.

7894. Is a statement of it submitted to the adventurers ?—The particulars of it are not submitted, but the books are always there, the cause of the payment from the club is recorded, whether it is for sickness or for hurt, and what kind of hurt it is; they sometimes take cold from exposure underground or on the surface, and if they have been long in the mine we consider them on sick pay.

7895. To whom is it considered that the club money belongs, to the adventurers or to the men ?—If the mine stops the balance of the club belongs to the adventurers.

7896. And they would be justified in dividing it ?—In adding it to the assets.

7897. Has that ever been done ?—Invariably, so far as I know in this neighbourhood.

7898. Do you know what amount it has ever been to any one set of adventurers ?—I could tell in one or two mines where I have had the closing up, but I cannot tell from memory.

7899. Will you furnish that ?—Yes.

7900. (*Mr. Holland.*) Has it been a considerable sum ?—No.

7901. (*Mr. Kendall.*) Have you ever known a considerable balance ?—There was a case, I think of Huel Prudence, in St. Agnes, which stopped a few years ago, and the men claimed a balance of club money, and I think the case was tried at Hayle.

7902. (*Chairman.*) How was it decided ?—That it belonged to the adventurers.

7903. Do you remember the amount in dispute ?—No, I could furnish it.

7904. (*Mr. St. Aubyn.*) Before whom was it tried, was it in the County Court ?—No, it was tried before the Vice Warden or the Registrar.

7905. (*Chairman.*) Can you give the date of that case ?—It was perhaps 12 or 14 years ago, that is the only disputed case which I have known.

7906. Do you suppose that that case rules the decisions ?—Yes, at least I have not heard of any dispute; you may look upon it in this way, some clubs may have 100*l.* or more in hand; and 700 or 800 hands employed on the mine being stopped, all the hands might be discharged to two or three, and the purser and manager might keep relations and charge them upon the club, and the whole would go to such individuals; a miner is always in a club, there are clubs in all mines.

7907. If a man has only just joined a mine how soon does he become a participator in any benefit from the club ?—As soon as he goes underground with his tools.

7908. In these mines with which you have been connected has the sum ever been considerable ?—At the Providence mine we have a balance in hand for the club of 268*l.* 13*s.* 5*d.*

7909. (*Mr. Kendall.*) How long has that mine been worked ?—Nearly 30 years. To show that we treat it as the adventurer's fund, 12 or 14 years ago our mine was very poor, and the hands much reduced, we then had 260*l.* in the club, and we transferred 100*l.* to the credit of the adventurers.

7910. (*Chairman.*) Do you happen to have with you the account of any other mine ?—Yes; the Huel Margery, 108*l.* 7*s.* 7*d.*

7911. Any other ?—In the St. Just Mines, Spearne Moor, 76*l.*; and North Levant, 104*l.*

7912. Can you state about the sum which has been received into the bank from either of those mines in one year ?—We pass it into the purser's account. The purser holds that in common with the other balances of the mine. We have no separate banking account.

7913. Would that account show the total amount which has been paid to the club account by the men during one year ?—Yes.

7914. Would the purser's account of a mine show the total amount which has been paid to the club account for one year ?—Yes; we make up our accounts quarterly and it is shown every quarter.

7915. Could you furnish that ?—Yes.

7916. I suppose that where a club account is very low there must have been a good many accidents ?—Yes.

7917. Will you state your reasons for adopting the plan which you have mentioned of the men paying a per-centage from their earnings instead of a fixed sum per month ?—I found that the Providence mine was very bunchy, and that the tributors would go on sometimes for three, four, or six months, and would get scarcely anything, and they then received a very small subsist; but yet their cost was always charged for the doctor and the club, and it went as a debt against the men, but it was paid by the adventurers; and when the men got a start of 20*l.* or 30*l.* a man they were only charged 1*s.* for doctor and club. Now, the average earnings of the tributers are a little over 3*l.*, and the 4*d.* comes in regularly, and it is no loss to the adventurers; we do not lose by paying the doctor or the club out of the adventurers' funds instead of the miners.

7918. But the charge would always be made against the tributor ?—When his earnings would admit of it.

7919. The debt standing against the men in the ledger for materials, club, and doctor is carried forward in the settlement of their account ?—Yes; when they can afford to pay it out of the balances.

7920. It is not remitted ?—No; it always stands against them, but we do not claim the debt unless they can afford to pay it out of their wages. We must allow miners to get a sufficiency to maintain themselves. If they are unsuccessful for months we grant them a subsist, and on that subsist we do not charge the doctor and club. When they get a start, if they get a 40*l.* start, they have 40*s.* to pay to the doctor and club.

7921. So that you consider that this is a relief to the men who are receiving only subsist, while at the same time it is an advantage to the adventurers ?—Yes; the adventurers are not charged with the doctor and club.

7922. How stands the case with regard to the doctor; how is the doctor paid ?—He is paid half of the charge of the doctor and club; that is divided equally between the doctor and the club.

7923. Then the doctor's income varies according to the men's earnings ?—Yes; but if you make up the men's cost it comes to pretty nearly the same.

7924. This plan is not generally adopted ?—No, it is not generally.

7925. How are the doctors appointed ?—They are generally appointed by the adventurers, but sometimes lords have a clause introduced in the leases giving them the power of appointment. In some mines I have known that it has been put to the vote among the men to choose the doctor.

7926. Is it in fact the agent who generally appoints the doctor, or is it at a meeting of adventurers ?—At a general meeting of the adventurers. All the agents are appointed by the adventurers.

7927. Do the doctors attend the agents' families gratis ?—No; I believe that it may be done by some, but others do not.

7928. Do the agents contribute to the doctor's fund ?—Not in our mine. Some doctors attend to most of the families of the agents, and perhaps of the men, but others do not.

7929. Do your doctors for that payment attend to the men's families as well as to the men themselves ?—No; only to the men and to those employed in the mine.

St. Ives.

Mr. S. Higgs.

2 August 1862.

7930. Are the doctors generally appointed for life ?—I suppose that it must last during good behaviour. It is very seldom that they are removed, but the appointment is during pleasure.

7931. Is there any payment to the barber in your mine ?—No ; that is rather a barbarous practice, and it is going out.

7932. In paying your men are they paid partly in notes and partly in gold ?—Partly in notes and partly in change.

7933. Have the men any difficulty in getting their notes changed ?—Sometimes they have, but not so much now as some years ago. Change is more easily obtained.

7934. What proportion of notes and of change do you pay ?—We pay a third in notes, or a quarter, just as it happens. To those who get 5*l.* we pay a 5*l.* note ; if men live together and they get 5*l.* we pay them in a 5*l.* note ; but if the pair are scattered and are in different parts of the country we pay them in change. We just ask the clerk as we go on, " Can " such a pair take a 5*l.* note or two or three," and if he is up to his work, he says, " Yes, one or two."

7935. Would there be any difficulty in paying them all in gold and silver ?—The bankers would rather that we took it in 5*l.* notes, but they are rather indifferent about it now ; formerly it was quite an object to them to pay in notes, but now they do not care much about it. We have no difficulty in Penzance at all ; we get a large quantity of change.

7936. Supposing it was found that the paying in notes induced the men to go to a public house in order to get the notes changed, there would be no difficulty at all in giving all change ?—No ; the shops and the publichouses in the neighbourhood generally provide themselves with change against the pay days in the neighbourhood.

7937. In the expectation that the men will want change ?—Yes ; they pretty well know how much change they shall require from the regular pay of the mine.

7938. Do you occasionally hear of boilers bursting ?—Yes ; and I think that mines ought to frame a very strict rule upon that head. We have now no means of punishing the men ; we cannot prove the negligence after the explosion, there is a difficulty ; we can only discharge them. But I think that they should be liable to punishment. We are about to frame a rule in our mines to meet such cases. All explosions are from neglect, and I think that that should be punished.

7939. May not an explosion take place from the boiler not being cleaned often enough ?—Yes ; the enginemen should point that out to the agents, or the agents should discover it. We generally have an engineer who attends the mines and whose duty it is to see to that with the agents, but we throw much as responsibility as we can upon the agents of the mine, so as to make them responsible.

7940. Is there any fixed period at which the boilers should be cleaned out ?—It depends upon the water which is used in condensing ; some boilers do not require to be cleaned out once in six months, and others require it every two months.

7941. Whenever a boiler is cleaned out is there a note kept in the books ?—No.

7942. There is no particular register of it ?—No ; a charge is generally made.

7943. But there is no regular register of the period when it is done ?—No ; it is within the memory of the people whose duty it is. Some boilers require cleansing every two months and others can run for six months, or even twelve.

7944. Is that left to the judgment of the agent or of the engine-man ?—The agents, and the engine-men, and the engineer : he visits the mine. They know the kind of water which is being used. There are some boilers which will be completely worn out in three or four years, and others will run for 20 or 30 years. We have been using boilers in this neighbourhood for 20 years or more. I think that we have a boiler in use which has been in use for 30 years

7945. (*Mr. Davey.*) Then you have good water ?—Yes, soft water, granite water, not mineralised in any way.

7946. (*Chairman.*) Have you heard in the last four or five years of many boilers bursting ?—The accidents have not been so numerous of late, but we had a case the other day in one of our mines where a boiler burst, and we are about to frame some rules to meet that.

7947. In which mine was that ?—At East Margaret.

7948. Did you ascertain the cause of it ?—We knew the cause, but we could not prove it, or we should have brought the man up.

7949. Was there loss of life attending it ?—No, fortunately there was not.

7950. What did you believe to be the cause of it ?—The feed was allowed to run down.

7951. Have you glass gauges to the boilers ?—No.

7952. Is trying with the gauge cock the only way which the engineman has of ascertaining the amount of water ?—Yes ; sometimes the water will spout from that ; if they are quick about it the water flows out instead of steam, and they shut it up. We have an order now that both the engineman going off duty and the man who relieves him shall see that the feed is up in the boiler when they change—that they shall each see that the boiler is properly fed.

7953. If they do not do that is there a danger of there not being sufficient water ?—Yes.

7954. (*Mr. Holland.*) What particular offences would you make punishable with respect to boilers ?—For neglect of attending to the feed of the boiler.

7955. What else ?—That is the only cause of explosion that we know of.

7956. Whose duty is it to see that the safety valves are all right and do not stick ?—The man in charge of the engine.

7957. If he neglected that, would not it be a punishable offence—ought it not to be his duty to see every day that the safety valve is right ?—Yes ; and some one of the agents should go into the boiler house constantly.

7958. (*Mr. St. Aubyn*). Did you ever know a case in which, from a multitude of accidents, or any other cause, the whole of the club money was exhausted ?—No, I never knew it in our neighbourhood.

7959. Supposing that it was to happen, the adventurers would, as a matter of course, advance any sum which might be requisite to meet the hurts of the men, would they not ?—Yes, there must be mutual confidence between the employed and the employer, or the work cannot go on well.

7960. (*Mr. Kendall*). Supposing that a man comes into your mine, say to morrow, and after being there a month pays his 1*s.* towards his club money, and supposing that he gets a hurt, and supposing that there is a large balance when he comes in of some 200*l.* or 300*l.* in the hands of the adventurers, and he has only contributed 1*s.*, and he is disabled for life, is not that man provided for as long as that mine exists ?—We allow 1*s.* a day for two years and afterwards 6*d.* a day.

7961. A man who comes in to-day, where you have a balance of 200*l.* or 300*l.* of club money in hand, if he gets hurt in two days, stands in the same relation as a man who has been for 30 years ?—Yes, I believe that this is always understood—we consider that a miner is in a club—if he goes from mine to mine he contributes to the club, and you may have 500 men contributing in a mine, and in a few years they may be reduced to 20.

7962. How long has the Providence mine been established ?—About 30 years.

7963. The club began at once ?—Yes.

7964. And the club has never been altered from that time to this ?—Never.

7965. After a few years you had a balance in hand ?—Yes.

7966. And I suppose that there is hardly a man who is now working in your mines who, when he came in did not find a balance in the hands of the adventurers as far as club money went?—We have always had a balance in hand.

7967. You have been working for 30 years, and you have scarcely a man working who, when he came in, did not find a balance of club money in hand?—We have always had a balance.

7968. You have said that you give a man so much money for the first two years, after that how do you get on?—We continue to pay miners 30*s.* a month if the club will afford it, and the man has a family, and we see that it is necessary. We never allow any of our men or their families to go to the union or apply to the union for relief; we find that the club is quite sufficient.

7969. If a man has once received a hurt in your mine, you never allow him after that to go to the union?—Never.

7970. You take care of him out of the funds?—Yes, if we find that the funds are sufficient to do it.

7971. You have been the purser of a great many mines, have you not?—Yes.

7972. (*Chairman.*) How many?—We have six in our office now.

7973. (*Mr. Kendall.*) Did you ever know a single refusal of the usual allowance to any man hurt in any mine?—No; it will vary. If a man is not an honest character, of course he has merely the strict allowance according to the rules, but it is very seldom that anything of that sort turns out.

7974. But if you find that a case is a very bad case, you would exceed the payment even according to the rule?—Yes, we should. If it is necessary to send a man to Truro or to Plymouth, we make an allowance from the club to pay his expenses up and down, and allow his family 30*s.* a month.

7975. What I gather from you is this, that you consider that, generally speaking, one shilling a month for the doctor and club out of the earnings of the men would keep the balance on the right side?—Yes; I have always found it so.

7976. Whether it did so or not, you would feel yourselves bound to pay the men one shilling a day?—Yes. We have no instance where the club money has failed. On the contrary, we find that we have sufficient sometimes to pay to a widow and her children.

7977. If you find that you are getting rich, do you go beyond the hurt money and go to illness, where you fancy that a man has become ill in the service of the mine?—Yes, we allow one pound a month. At this time at Providence mine, I think that we have only one person upon the club fund this last month, next month, perhaps, we may have two or three. I have found in all our mines that the club money is sufficient to provide for hurts and for sickness.

7978. You have spoken of start, and of men getting large wages; though you do not go under ground much, I suppose you know as much of the underground operations as if you did?—Yes, from the plans; I have never been under ground except from curiosity.

7979. Do you know anything of the mode of working there?—Yes, I understand it pretty well.

7980. Suppose that a man working by tribute, gets a start, if there are two men or four men in a pair do you allow them to vary the numbers?—No, not from the taking, if four men take they are expected to work out the month as four men.

7981. (*Mr Holland.*) Supposing that a man is receiving hurt pay from a mine that stops, what becomes of him then?—He is entitled to it for two years.

7982. But suppose that the mine stops?—Then if there are sufficient funds you pay him for two years.

7983. After the mine stops?—Yes.

7984. The adventurers are bound to do that, are they?—Yes.

7985. Can you make a call upon the adventurers to pay that?—No.

7986. Then in that case a man would become a pauper, would he?—We do not know any such instance; it is just a possible case, but I do not know of any instance of the kind.

7987. (*Mr. Davey*). Did you ever know an instance where after a mine has stopped the balance of the club money has been divided pro rata among the men?—I knew an instance where a man received 30*s.* a month for 18 months, sufficient was kept from the balance to pay him that.

7988. Would the whole of the balance or the money in the hands of the purser belonging to the club be divided pro ratâ to those sick people having a claim upon it?— No, I have never known but one instance where a man has been chargeable to the club where the mine has stopped.

7989. Do you subscribe to the infirmary in any of your mines?—Yes.

7990. Do you charge that to the adventurers or to the club?—It is paid out of the club.

7991. (*Chairman*). Which infirmary is it?—The Truro infirmary.

7992. (*Mr. Davey*). You have known St. Just for a great many years, what do you consider to be the state of the miners generally? are they in as good a condition now as they were when you first knew them?—Yes, they are better decidedly.

7993. Supposing that the Providence mines cease to work to-morrow, and that you had two or three claimants upon the club, and you paid them off, what would you do with the balance?—We should divide it among the adventurers, we should use it as an asset.

7994. (*Chairman.*) Have you some statements which you would like to put in?—I have the average earnings of the tut and tribute men in separate mines, they come very near.

7995. Can you furnish the commissioners with the average earnings of the tut work and tribute men in the Providence mine?—Yes, you have it here for a quarter, and you can have it for six months, or any longer period. I have it for Providence mines, Huel Margery, Trelyon Consols, East Margaret, Spearne Moor mine, North Levant mine, and Huel Reeth.

The witness delivered in the same, which is as follows:

AVERAGE WAGES THREE MONTHS.

7996. (*Mr. Holland.*) Would it be desirable to raise the subscription of the club to provide for sickness as well as hurt?—We find in our mines that it is sufficient.

7997. For all the cases of sickness?—Yes.

The witness withdrew.

Captain William Hollow examined.

Capt. W. Hollow.

7998. (*Chairman.*) You are captain of the Providence mines?—Yes.

7999. Have you charge of any other mines?—No.

8000. Are the Providence mines copper and tin?—Yes; principally tin.

8001. What is the greatest depth?—The greatest depth of the shaft from the surface is 170 fathoms.

8002. Is there a level at that depth?—Yes; but we are not doing anything down at that depth.

8003. What is the greatest depth of any level at which you are working?—The greatest depth at which we are working is about 130 fathoms from the surface.

8004. What is the greatest heat at any of your levels?—I do not know.

8005. You have never tested it?—No.

8006. Are there any what are termed close ends?—No. The greatest distance which we have from the shaft is about 110 fathoms perhaps.

8007. In that distance how many winzes are there?—There are several winzes and places worked on tribute. I should think that the nearest winze might be about eight or ten fathoms. I cannot say exactly.

8008. How far from a winze would you consider it safe to hole?—About ten or twelve fathoms. If we can cut a good bunch of tin or copper, we sink a winze a little closer than we should with a very poor piece, but from ten to twelve or fifteen fathoms would be about the distance.

8009. Do you sink a winze only for the purpose of ventilation?—Not in the Providence mine; our mines are very singular, we are not like many other mines on the course of the lode. The greater portion of our operations are off the lode. If the lode is east or west the greater part of our operations will be going north and south, or north-east and south-west, so that we can hardly give an estimate.

8010. Sufficient ventilation in your opinion is provided by merely working the tin?—Yes, quite so. In the eastern part of the mine it appears to me that we get out of the range which I have stated, and there the lode is pretty productive; there we sink winzes pretty regularly.

8011. For the purpose of ventilation alone?—Yes.

8012. Have you ever had to apply any additional means for ventilation?—Yes, at times.

8013. What mode have you adopted?—We have a cylinder, what we call a piston, and we pump air through pipes.

8014. From the engine?—From the engine. Our engine is always going from eight to ten strokes a minute; that is only just for the present moment when we have to ventilate any particular winze or shaft.

8015. From that it is carried by what kind of pipe?—By an iron pipe through the levels.

8016. To the point where the men are working?—Yes.

8017. Do not the iron pipes corrode very much?—No.

8018. What is the size of the pipes along the levels?—About five inches.

8019. How near can you carry one of those pipes to the point where the men are working?—Within about two fathoms, just out of the way of the blasting; in fact we have had them in the mine for the last two years and they have not been used; they are only used on very particular occasions.

8020. But you have the means of forcing in air when it is required?—Yes.

8021. In those ends, how long generally is the powder smoke in clearing away after an explosion?—Not long; I cannot tell you to perhaps half an hour; when the men come back they can go in to work again, but in our mine, where it is not on the lode, we only blast once a day, just when the men leave work.

8022. How many corps work there?—We work generally in a single corps. We find that men will do better in a single corps than by working four in a pair.

8023. At what time do they go down?—They go down at six and come up at two; that is our usual time.

8024. Is not there another corps which then goes down?—Only a small portion compared with those that go down at six.

8025. By a single corps do you mean single-handed?—No; there are two men. By a single corps I mean eight hours out of twenty-four.

8026. What is your reason for having only one corps?—Our reason is simply because we have so many parts in our mine which we should like to try, and we fancy that by putting on 8, 12, 15, or 20 tutwork bargains we should find a chance, and if we should ever cut anything, which we do sometimes, we increase our men; we put from two to four; the mine is so bunchy that we are constantly trying.

8027. What proportion of tribute men have you to tutwork men?—Our tribute men are 94, and our tutwork men are 80?

8028. Do you take any precautions to prevent accidents from blasting?—No, not particularly. I have been on the mine now seven years, and we have not had a single accident of any sort or kind from blasting.

8029. Are the men supplied with any particular tamping rods?—They are supplied with a piece of hard wood to settle down the powder before putting

in the iron, they have that from the carpenter's shop. It is our rule that if any accident should occur, and they do not happen to have one of these hard wooden rods, they do not come upon any pay from the club.

8030. Is that in the rules ?—I do not know whether it is one of the printed rules, but that has been read out at the time of setting, several times.

8031. But they use for finishing off the hole an iron tamping rod ?—Yes. Our ground is all dry ground, perhaps that may be in favour of our not having such accidents as there might be in wet ground.

8032. I suppose that you have no poor air ?—No, we have not any in the mine.

8033. To your knowledge, are there any men working with you who have been affected from working in other mines ?—No, not that I know of. I do not hear any complaints whatever. We have some in the mine about sixty years of age ; we have none in our mine above sixty-two underground, but we have several from fifty to sixty.

8034. How many boilers are there in the Providence mine ?—We have two at the engine.

8035. Have you only one engine ?—Only one pumping engine.

8036. Have you any other engine ?—We have a steam wym and a stamp ; we have two boilers to the pumping engine, and one to each of the other engines, that is four altogether for the three machines.

8037. Have you any water gauge ?—No, we have what we call gauge cocks.

8038. So that it must rest with the engine-man to try the gauge cock occasionally ?—Yes.

8039. How often is he bound to try it ?—I do not know that he is particularly bound, he must use his own judgment. I do not know that we have any specified time that he shall try it.

8040. When another man takes his place, is he bound to try it ?—It is the rule that when a man turns in he is to try the gauge cocks the moment he comes in.

8041. But there is no way of ascertaining whether that is done ?—No. Sometimes we agents are on the spot, and we see that it is done.

8042. How often are your boilers cleaned out ?—Once in two or three months, just when it suits. The water with which we condense is good water, in fact pretty nearly good enough to drink ; so that once in three months is just about as often as we require it.

8043. Do you test the boiler in any way in order to see whether it is necessary to clean it out ?—No ; we make a rule just when it suits from two months to ten weeks.

8044. (*Mr. Holland.*) Do you look at the blow-out water ?—Yes, we use our own judgment as to that.

8045. (*Chairman.*) Do you keep any record of the times when you clean the boilers ?—No other than our rough cost book, when the charge is made for cleansing, and we charge the money, so much for cleansing; but we find that it is about once in three months.

8046. But it is left to your discretion when the boiler shall be cleaned out ?—Yes ; I may state that our men are very well satisfied.

8047. How do the men ascend and descend ?—In the ordinary way, by the ladder ; but ours is a very easy ladder ; our ladders are not more than about 20 feet. Sometimes they will run to 22 or 23 feet, but about 20 feet is the rule.

8048. (*Mr. Holland.*) You mean 20 feet from soller to soller ?—Yes.

8049. (*Chairman.*) How are the tools sent up ?—They are sent up and down by the steam wym. We do not allow the men to carry any tools.

8050. What distance is there between each tread ?—About ten inches. Our men are not allowed to change in the boiler houses. We have a good dry.

8051. Do the women work under cover ?—Yes.

8052. Have you any separate place for the women to get their meals in ?—There is a house appropriated for that purpose. We take all the care we can.

8053. (*Mr. Holland.*) Are the boilers under your charge ?—I am the agent, but I am not the engineer; we have a paid engineer. Of course I give orders when I think that they ought to be cleansed; and after letting them stand for three months, we find that they are quite safe.

8054 When the boilers are cleansed, are the plates carefully examined ?—Yes.

8055. To see that there is no bulging ?—Yes ; one agent or the other goes in, not every time that the boilers are cleansed, but occasionally.

8056. Is the state of the boilers tested at any regular intervals ?—No, not by any particular pressure.

8057. Then they might weaken without your finding it out ?—They might.

8058. Do not boiler plates constantly weaken ?—Yes, certainly they do.

8059. Then you have no security that they are not getting dangerously weak, except what you observe when you go in ?—We have not ; we work at very low pressure.

8060. At what pressure do you work ?—We do not work more than about 30 lbs. to the inch.

8061. I suppose that you have a float to govern the feed pipe ?—Yes.

8062. Whose business is it to see that that is all right ?—It belongs to me as the agent.

8063. Is it carefully looked after ?—Yes.

8064. Regularly ?—Yes.

8065. Are the safety valves regularly looked after to see that they do not stick ?—Yes, I generally test them every day or every other day.

8066. Have you one or two safety valves to each boiler ?—We have only one to each.

8067. Are the boilers connected ?—Yes.

8068. There is the same steam pipe for both boilers ?—Yes.

8069. Do you think that that is safe ; is that common in Cornwall ?—Yes ; it depends upon the pressure principally, I should say. It depends on the state of the mine. Where you have four or five boilers, I think that it would be necessary that they should be kept separate at times. We are so easy, compared with the eastern mines, at least our water charges and our mines are so easy that we think everything is safe.

8070. (*Chairman.*) There is plenty of boiler power? —Yes.

8071. (*Mr. Holland.*) You have spoken of a ventilating engine, is that at the surface ?—No, that is fixed down in the shaft at one of the airiest places that we have.

8072. What is the size of the cylinder ?—Twenty inches.

8073. What stroke ?—Six feet. It is just like any other cylinder of a steam whim. We find that it will pump air 150 fathoms, and will blow a candle out at some distance from the mouth.

8074. Is that only at one end ?—Yes.

8075. (*Chairman.*) Could you divide it ?—Yes, and for this reason,—it will pump two strokes of air to one stroke of the engine, and we might put one stroke east and the other west if we were driven up, but we generally find that only one end wants ventilating at once.

8076. (*Mr. St. Aubyn.*) Is yours a right-down shaft ?—Yes.

8077. Have you any experience of the man-engine ?—No, but I have seen it.

8078. Have you any experience of the skip to carry the men up and down ?—No.

8079. (*Mr. Davey.*) In what parish is your mine ? —In Lelant.

8080. Is that this side or the other side of Penzance ?—It is this side ; it is about a mile and a half up.

8081. Have you any scarcity of men here ?—No, not so all ; in fact, we are so swarmed with them that we hardly know what to do with them, and particularly within the last three or four months.

St. Ives.

Capt. W. Hollow.

2 August 1862.

8082. What priced ground have you generally ?—On the lode from 4*l.* 10*s.* to 6*l.*

8083. Do you think that you could break that ground better single handed than by having two men ?—I do not think we could.

8084. I ask the question because in some neighbourhoods it is said they can do better single-handed than with two men ?—We do not find it so ; we have only four or five ends driving on the lode, and we do not think that it is worth while to make any alteration in those particular parts.

8085. Do you consider it necessary to have two men in a corps for ground of 3*l.* or 4*l.* a fathom ?—Yes, I do. The men in our district do not like single work at all, in fact, they could not do it.

8086. You have been asked whether your boilers have ever been tested ; supposing that the boiler was properly attended to, and the water was of a proper gauge and that there should be a bare place in that boiler, how would that show itself, would there be an explosion, or merely a break out of a little steam ?—We have had some of those cases, and they have merely broken through.

8087. There has been no explosion ?—No, not at all ; first of all it will drop, and when we find it drop or leak we stop it at once.

8088. Do not you attribute nearly all the explosions to the neglect of the gauge ?—I do as far as I am a judge ; I do not profess to be an engineer.

8089. And not to the weakness of the boiler ?—Yes. I think that they are all to be attributed to neglect.

8090. Would it in your opinion be necessary or desirable to have the gauges which you say you have seen in other mines ?—I do not think that they would be at all amiss.

8091. Would they add considerably to the security of yourself and the enginemen ?—They are like every other thing, they require looking after, but I think that they would not be amiss.

8092. Do you not think that they would add to the security of the mine ?—Yes. I have seen them in steamers, and so on, and I think that they would add to the safety of the enginemen, and of ourselves, because very often they would see the gauge when they might be too lazy to try the cock. Those gauges are not at all costly ; I think that the great mistake very often is that parties are put to work the engines who are not competent.

8093. (*Chairman.*) And therefore every indicator of danger would be of advantage to an inexperienced man ?—Yes.

8094. (*Mr. Davey.*) What class of people do you employ as engine men ?—We have them on the mine who were there before I was there ; they very seldom change. They have been there for the last seven years, and how long they were there before I came there, I do not know.

8095. Is it usual to employ a man in that capacity who has received an injury in some other part of the mine ?—That has been done in some places, but we are always very cautious not to take in what I call a greenhorn if we want a man I would rather have somebody else to be troubled with him than that I hould.

The witness withdrew.

Captain William Stevens examined.

Capt. W. Stevens.

8096. (*Chairman.*) I believe that you are captain and manager of Huel Reeth ?—Yes.

8097. Have you charge of any other mines ?—No. at present.

8098. What kind of ore does your mine produce ?—It is a tin mine.

8099. Entirely ?—Yes.

8100. How many are there employed underground ?—About 150.

8101. Men and boys?—Yes.

8102. How many above ground ?—About 50.

8103. Are there many children amongst those above ground ?—Yes ; some of them not more than eight years of age.

8104. Boys of eight years of age ?—Boys and girls.

8105. What is the depth of your deepest shaft ?—250 fathoms from the surface.

8106. What is the deepest level in which you are working at present ?—250 from the surface.

8107. In what manner do the men ascend in your mine ?—We have a man-engine.

8108. Is it a single or a double man-engine ?—Single.

8109. How long have you had it ?—About two years.

8110. Have you ever had an accident ?—No.

8111. Do all the men use it ?—Yes.

8112. They come from the distant parts of the mine below ground to come up by the man-engine ?—Yes.

8113. Are you able by having the man-engine to employ older men than you would otherwise ?—Yes ; very much indeed.

8114. More experienced men ?—Yes.

8115. Do you think that an advantage ?—Yes ; very much so.

8116. You would sooner have an experienced miner than a young hand ?—Yes ; we would rather have one older man than we would have three of the young ones.

8117. What would you call a young man ?—Before we had the man engine there, we could not get men above 20 years of age to go down to the bottom of our mine.

8118. And now of what age are the oldest men ?—Sixty.

8119. Therefore you think that providing this means of ascending and descending has been a great advantage to the adventurers ?—Very great.

8120. Can you state any other way in which it has been an advantage to the adventurers ; do you get more work from the men ?—Very much. Before we had a man engine perhaps we were obliged to give 12*l.* a fathom for ground, and we have got it now worked for 9*l.*

8121. (*Mr. Holland.*) Is that difference solely due to the man-engine ?—Yes.

8122. There is no other difference than the man-engine ?—No.

8123. And three men now do the work of four ?—Yes.

8124. (*Chairman.*) Are you working in killas, or in granite ?—In granite.

8125. Have you any hot levels ?—Yes, we have them pretty hot. Ours is the deepest mine in the district, and we have some places distant from ventilation where it is hot.

8126. Have you ever tested the heat at all ?—Yes.

8127. What is the greatest heat ?—From 85 to 90 degrees.

8128. That is when working at a close end away from ventilation ?—Yes.

8129. Do you provide any artificial means of ventilation ?—Yes.

8130. Will you describe what those means are ?—If we have 15 or 20 fathoms from one ventilation to another, we put down a winze from one level to the other, so that the men shall have proper ventilation.

8131. Have you any artificial way of blowing air n ?—No ; we have three working shafts in our mine, and in the western shaft the air goes down, and it goes through the mine and comes up the eastern shaft.

8132. Is that always the case ?—Always ; it never varies. We are obliged to put a door, what we term a trap-hatch, and if we take up that trap-hatch the men working in the level below cannot carry a candle in their hands. We can give as much draught as we like.

8133. By means of your shafts and winzes you can

provide all the air that is required in the lowest and the hottest level ?—Yes.

8134. When you come to 14 fathoms from a winze how do you get air into that point where the men are working ?—We can always get ventilation at 14 or 15 or 20 fathoms from one winze to another.

8135. What is the greatest distance at which you have ever holed from a winze or a shaft ?—We have gone as much as 30 fathoms.

8136. When you have got, say to 29 fathoms, have you found it hot ?—Yes.

8137. Had you any means of cooling that end while the men were completing the other fathom ?—Yes ; we have put in an air machine.

8138. What description of air machine ?—A fan machine we term it, and with boys to work it to blow in air.

8139. That I suppose is put near the winze ?—Yes; it is put where we can take up good air from.

8140. And 20 or 30 fathoms from where the men are working ?—Yes.

8141. What security have you that the boy continues to drive it, that he does not go to sleep ?—The men will watch that.

8142. If the men felt it get warm they would communicate with the boy ?—They would very soon give the boy a lesson.

8143. You think that the fan completely supplies them with good air at the end where they are working ?—Yes.

8144. Have you ever tried how much it reduces the temperature is reduced at the time when the fan is applied compared with what it was before the fan was worked ?—No ; I cannot answer that question.

8145. (*Mr. Holland.*) Does it make it decidedly cooler ?—Yes.

8146. (*Chairman.*) Do you ever put in air sollers ?—Yes

8147. Which do you prefer, an air soller or a machine worked by hand ?—I prefer an air soller, but there is not every place convenient to put in an air soller.

8148. Do you put your air soller at the top of a level or below ?—At the bottom.

8149. How long is the smoke in clearing away in your closest ends ?—Perhaps an hour and a half.

8150. Do the men go in before that ?—The men, if they do blast their holes, do it when their core is up.

8151. How long would the smoke be clearing away if the fan was at work ?—Not more than a quarter of an hour.

8152. (*Mr. Holland.*) That reduces the time from an hour and a half to a quarter of an hour ?—Yes; the men may go in in a quarter of an hour.

8153. (*Chairman.*) How long have you been manager at this mine ?—18 years.

8154. I suppose that during that time accidents have occurred from blasting ?—Yes ; we have had two or three accidents, but we have been very lucky ; we have escaped very well.

8155. Have any accidents occurred in the last two or three years ?—Yes ; one accident.

8156. Did you ascertain what the accident was occasioned by ?—It was rather by the neglect of the men.

8157. In what way ?—They were not careful enough in putting the powder into the holes.

8158. What kind of tamping rod do the miners use ?—We have a safety fuze which we use and very good tamping, but the man did not take care enough ; he used iron, whereas he ought to have used wood.

8159. Did you supply him with a wooden instrument ?—Yes; and the man ought to have used the wooden rod.

8160. Did he admit that he had not done so ?—Yes, he allowed that he had used the other.

8161. Do you use cartridges in your mine ?—Occasionally ; if we have a piece of ground where it will do.

8162. Have you never known an accident occur after the powder has been put into a hole from the edges of it not being swabbed round ?—No, I cannot say that I have.

8163. But might not an accident happen in that way ?—Yes. If there is powder lying round the hole and they put in the iron instead of the wood first, which causes the fire to strike.

8164. Might not an accident also occur in picking out the hole when the powder has not gone off ?—Yes; I have known an accident of that kind to occur, and it will happen if the men are not very careful.

8165. If the powder was made into a cartridge there would then be no danger of the powder lying loosely round the hole ?—I do not think that.

8166. Would there be any powder still lying about the hole if it were contained in a cartridge ?—No ; but I would as soon trust to putting the powder into a hole without a cartridge as with one.

8167. But there would be no powder lying about the sides of the hole if you used cartridges ?—No.

8168. How many boilers are there at your mine ?—We have four machines to the draught-engine ; we have two boilers, and to the other three we have one boiler to each.

8169. Making five boilers altogether ?—Yes.

8170. Are they under your own special charge ?—Yes.

8171. How often do you examine the boilers ?—We examine them every day.

8172. How often do you clean them out ?—Once in about three months.

8173. Is each boiler cleaned out once in every three months ?—Yes.

8174. Is there any record kept of the time when they have been cleaned out ?—Yes, our books will tell. We pay the men for doing so.

8175. Does the water used cause corrosion, or is it in any way injurious ?—The water that we use is very good water.

8176. Has an accident never occurred from the explosion of a boiler ?—No.

8177. Have you printed rules for the management of your mines ?—Yes.

8178. What quantity of candles do you allow to the miners per week ?—2 lbs. to every man and to every boy.

8179. Do you ever allow them more than that ?—No ; that is their quantity, unless they break open the chest and steal the candles.

8180. Without good reason you would not supply them with any more than the quantity you have stated ?—No.

8181. What do you charge the miners for the candles ?—8*d.* a pound.

8182. Where do you obtain your wholesale supplies from ?—Mr. Higgs is the adventurer, and very good candles they are.

8183. What is the charge that you make for the powder ?—8*d.* a pound.

8184. Do you use any particular patent powder ?—No.

8185. What is the sum that you deduct for the club, and is it to provide for visible accidents or for sickness ?—The rules of our mines say for visible accidents, but Mr. Higgs and our masters are all very kind.

8186. (*Mr. Holland.*) What do you estimate to be the average saving of labour by the use of the man-engine ?—About one quarter.

8187. In the shallower levels it would not be so much, I presume ?—Yes, they will not climb the ladders at all.

8188. But those men who only go down to the shallower levels are not saved so much as those who descend to the deeper levels ?—Yes ; they go to the man-engine, they will not climb up the ladders.

8189. What is your estimate of the average saving, taking into account the whole of the men, those who go to the deepest levels, and to whom most is saved, and those who go to the shallower ones, and to whom less is saved, is it as much as a quarter ?—Yes.

ST. IVES.

Capt. W. Stevens

2 August 1862.

8190. About how much does a man-engine cost ?—About 2,000*l.*

8191. Is it a very profitable investment ?—Yes.

8192. You have spoken about ventilation, and you stated that there was a door which, if left open, left the men at the bottom almost without air, but which when shut supplied them with a good draught?—Yes.

8193. (*Mr. St. Aubyn.*) How long has the man-engine been in operation ?—About two years.

8194. Has it effected a considerable saving ?—Yes.

8195. How long do you think it will take to repay the cost of it?—We get a quarter part more work done ; I cannot say.

8196. What is your monthly expense ? — About 80*l.*

8197. Then in about two years you will have repaid yourselves ?—In from two to three years.

8198. Have you had any experience in carrying men up and down the shafts by a skip ?—Yes, when we first began, the men used to get into the skip and ride up and down.

8199. Was that with your permission ?—No; we were against it.

8200. Have you been connected with any mine in which it has been allowed ?—No.

8201. Do you consider the skip dangerous ?—Yes, with a chain.

8202. How do you think it can be made safe ?—If you had a rope you could see where the danger was, but with a link you cannot tell it.

8203. You think that with a hempen rope properly looked after there would be no danger?—Yes; you can see then where there is a failure, but you cannot see it with a chain.

8204. (*Mr. Kendall.*) Do the lords in any way contribute to the expense of the man-engine ?—No.

8205. Did you ever ask them ?—No.

The witness withdrew.

Mr. GEORGE WILLIAM BEVAN examined.

Mr. G. W. Bevan.

8206. (*Chairman.*) Will you be kind enough to state the mines to which you are surgeon ?—The Providence mines, Wheal Reeth, Lelant, Worvas Downs, Trelyon Consols, and Wheal Margery mines.

8207. How long have you acted as medical attendant at any one of these mines ?—I have been connected with the Providence mines, I think 28 years.

8208. And how long have you been connected with Wheal Reeth ?—About 17 or 18 years, I think, since she has been working the last time.

8209. You were acquainted with the Wheal Reeth mine, I presume before the man-engine was introduced ?—Yes.

8210. Do you think that that has made any difference in the number of cases of miners that have come before you ?—It has been so shortly put up that there has not been much trial of it ; I think there is no doubt that it will be a great benefit to the men.

8211. Have you had any opportunity of judging whether it is accompanied with any advantage to the health of the men ?—Not at present, but there is no doubt that it will be, it will save them a great deal of labour.

8212. Have you observed whether there are now older men working in the mine than there were before? —I have not had any opportunity of observing, for at present the men are so healthy.

8213. Are there any men now who are out of work from ill health ?—Not one; I have had to attend but one man for the last fortnight, and he is a man who has been working at grass, but he has been a diseased man for the last 20 years.

8214. Are there any men working now who have been during the last two or three years on your sick list ?—Yes.

8215. Were any of those suffering from what is called miners' disease ?—Not particularly so ; they are cases generally of colds and derangements of the stomach, and feverish cases.

8216. Were any of those ailments, in your opinion, caused by working underground ?—Not particularly so, no more than an epidemic that has been prevailing occasionally, a slight case of influenza, or a slight attack of bronchitis.

8217. Are none of them affected in their breathing? —Very little ; no more than what you find from any ordinary cause.

8218. Are you able to say that the men under your charge here do not suffer from miner's disease ?—Not so much as in many places.

8219. Do they suffer at all from that disease ?—Occasionally.

8220. Do you keep any record of the cases that come before you ?—No, not all.

8221. Have you ever made any post mortem examinations ?—No ; I have endeavoured to do so several times, but I have not been allowed.

8222. Do you go at all underground ?—No.

8223. Have you ever been underground ?—Not for many years.

8224. Then are the Commissioners to understand that there are no cases of men working in the mines in this district who are effected in their breathing ?—There is only one man that I am aware of in the mines that I have attended, and he is a man who has been subject to attacks of bronchitis for several years, he continued working underground rather too long, but still he is capable of following his labour.

8225. Is he working underground now ?—No.

8226. How old is he ?—About 56.

8227. How is he employed at the present time ?—He is working on the surface.

8228. What is the number of men employed in the different mines of which you have charge ?—I cannot say.

8229. Can you state the number approximately ?—I think that in the Providence mine there are about from 200 to 300. In the last statement of account, I think that the agent told me, that of labourers there were about 300 underground and on the surface.

8230. Have you kept no record whatever of the number of cases which have come under your notice in the course of years ?—No ; the time does not admit of it.

8231. You have kept no record at all of the number ?—Not at all ; it would be interfering with the other business.

8232. Have you other practice which is rather extensive ?—Yes ; I have an extensive practice in the neighbourhood.

8233. Among the agriculturists ?—Yes.

8234. Do you perceive any difference in the health of the agriculturists as compared with the miners ?—There is not that difference now that there was some years since, in consequence of the improved ventilation of the mines, and also in consequence of the miners paying more attention to themselves than they did formerly ; the miners generally speaking have become more moral men in all their habits and conduct.

8235. More temperate ?—Yes ; and they pay more attention to themselves, and the mines are better ventilated than they were formerly.

8236. In what way are they better ventilated than they were formerly ?—By extending the levels and sinking pits, so as to communicate air from one part of the mine to another.

8237. As a mine becomes worked more extensively, you think that the ventilation is improved by it ?—Yes ; if they did not do that, the men could not work properly, and it would be a disadvantage to the adventurers.

8238. As a mine becomes more extensively worked, it must of necessity, must it not, become better ventilated ?—Yes, if they value their own interest ; but in some instances it is not the case.

8239. Are there any such instances within your knowledge?—There is one mine that is not now working—the Gew mine.

8240. How long has the working in that mine been stopped?—For two or three years.

8241. Was that mine not well ventilated?—No, it had only one shaft.

8242. Had you charge of the mine at that time?—Yes, partly, several years since, and a great number of persons suffered.

8243. (*Mr. Holland.*) What did they suffer from?—From miners' disease—pulmonary disease.

8244. (*Chairman.*) Will you be good enough to describe what you mean by miners' disease?—A cough and expectoration—disease of the bronchus, extending to the lungs, and in the last stage the lungs give way; it is caused by imperfect ventilation.

8245. At the time to which you refer did many cases come under your notice?—Yes, a great many.

8246. Are there no other mines in which the miners have so suffered?—Not where they have suffered so much.

8247. But where they have suffered at all?—Not to the extent of those working in the mine referred to.

8248. Are you able to state whether any miners are alive now who had suffered from working in that or any other mine?—I cannot recall their names.

8249. Could you furnish the Commission with a list of any miners now alive who suffered from working in that or any other mine?—I cannot now recollect their names.

8250. Is it not your habit to enquire for the name of the mine at which the miners are working?—No; they know that there is a medical attendant belonging to the mine, and then they come to him.

8251. Do they ever come to you in preference to going to the medical attendant who has been appointed to a mine?—Yes, very frequently; and sometimes I attend for a friend.

8252. Do miners ever come to you from other mines?—Yes, very frequently.

8253. Is that in consequence of their not being satisfied with the medical treatment they have received?—Not at all; it is perhaps from my being nearer—perhaps they might not be near to reach their medical attendant—they might work in a mine from which he might be four or five miles off.

8254. In a case where the medical attendant resides four or five miles away, how often does he visit a mine?—Not at all, unless he is called upon.

8255. Then have the men to go that distance to him?—Yes, sometimes they have; and if they are not capable of going the medical attendant attends them at their own house; in case of fever or accident they are particularly attended to.

8256. How are the medical men appointed?—By the adventurers.

8257. Is there often a competition between the different medical men to obtain the appointment?—Very seldom; as in other cases the medical men have their friends, and they get appointed.

8258. Do they apply through their friends, and through the adventurers?—Yes, sometimes, and by becoming an adventurer in a mine is appointed surgeon. I have been an adventurer in the Providence mines ever since they first commenced.

8259. You were appointed surgeon?—Yes.

8260. And you were an adventurer at the same time?—Yes.

8261. Do medical men often become adventurers in mines for that purpose?—Not always; some men are fond of speculating in the mines.

8262. And they may speculate for the purpose of obtaining employment?—Yes, that is one advantage.

8263. (*Mr. Holland.*) Do you consider that the miners are a long-lived race of men?—Not generally speaking.

8264. Are they a short-lived race?—I think that within the last few years they have become longer-lived than they were formerly—in the early part of my time the average age of a miner was considered about 35 or 40.

8265. What is it now?—A great many of them have died in this district at the age of 80.

8266. But what should you consider was the average age of a miner?—From 50 to 55. I see a great number, and we had an old man working in the Providence mines some time since of the age of 75; there is a vast difference in the health of the miners in the copper and tin mines.

8267. Are you prepared to state to the Commission as the result of your experience, that the miners are nearly as long lived a race of men as other labourers?—In this district I think they are.

8268. Do they suffer in a very marked manner from lung disease, as compared with other labourers?—That depends entirely upon the mines in which they work.

8269. I am speaking now of those to whom you attend?—Yes; it is certainly more marked in the miners than it is in the agricultural labourers.

8270. Is there or not a larger proportion of lung disease among the miners than among other persons?—A greater proportion among miners.

8271. What is the form of lung disease from which they suffer?—Generally speaking, and very often, it assumes the form of tubercular disease.

8272. Is it generally so?—Yes.

8273. Do you feel well assured of that?—Yes, in the latter stage it becomes tubercular disease; you see great expectoration of sputa.

8274. Is that from tubercular disease?—Yes; there is generally ulceration of the lungs.

8275. But there may be ulceration without tubercular disease?—Certainly, which is to be distinguished by the appearance of the expectoration.

8276. Are you familiar with the use of the stethescope?—I use it sometimes.

8277. Do you find among miners physical signs of disease in the upper parts of their chests?—Generally speaking it is in the upper part or about the bronchus—in the latter stage the lungs give way.

8278. Do you find that hæmoptysis is common among the miners?—Very often.

8279. Do you think it is so in a large majority of cases?—Yes.

8280. Do they throw up liquid blood?—Yes, immense quantities.

8281. Is that common?—Not so common as it was some years ago in this neighbourhood, and not so frequent as it is in the neighbourhood of Redruth; because they find more arsenic in the copper there than we do here.

8282. Do you think that you can distinguish tubercular consumption from chronic bronchitis by the character of the sputa alone?—Yes, I think I could; but in many cases the sputa is similar.

8283. Not by the character of the sputa alone?—Sometimes.

8284. By auscultation do you frequently find the upper part of the lungs consolidated, and in an early stage of the disease?—I have never remarked that.

8285. Do you frequently find indications of cavity in the upper part of the lungs early in the disease?—So far as I could judge by the sound I think so; when you place your ear to the chest, you often hear a sound as if the part was completely empty.

8286. Is not the sound rather that of mucus in the bronchus than in a cavity?—Not in the lower part of the chest.

8287. I understood you to say that it was in the upper part of the chest?—In the early stage of the disease it is more in the upper part of the chest of the miner; you find it about the bronchus before.

8288. Do the miners suffer early from hectic?—No, they do not.

8289. That does not come on until later?—No.

8290. In phthisis it comes on earlier?—Yes, but it will be found that miners will go on for two or three

St. Ives.

Mr. G. W. Bevan.

2 August 1862.

years, the lungs will not give way; they live, and are able to do a little work.

8291. Have you observed that miners who have been suffering from the disease got pretty well again if they come to work at grass?—Yes, there is one man that I attended several times for bronchitis while he was working underground. I told him that if he did not discontinue it, he would shorten his existence, and at last he was obliged to give it up; his name was Noy.

8292. Would such a man if he were to come to work at grass have a fair chance of prolonging his life?—Yes, perhaps for many years.

8293. If a man was suffering from common phthisis that was far advanced, do you think he would have a fair chance of living many years by any change whatever? —I think not.

8294. Have you seen that frequently in miners?—

8295–8. I am drawing a distinction between miners and men not miners who have all the symptoms of ordinary consumption far advanced; can that disease, in men, not miners, be commonly suspended for many years?—Not for many years.

8299. Are they not very rare exceptions?—Yes.

8300. Whereas they are the common examples in miners' disease?—Yes.

8301. Does not that seem to point out a great difference between the two diseases, that one disease can be suspended for many years commonly, and that the other can be suspended for years only very uncommonly?—There are cases, but with the miners they have not got that support to sustain life in the same way that another person might have under the same circumstances.

8302. You allude to their food?—Yes.

8303. Are the miners, speaking of them as a class, a poorer class of men than the ordinary labourers?—Yes, generally speaking they are, they marry early, and involve themselves.

8304. Is not common consumption among men who are not miners most usual between the ages of 20 and 30?—Yes.

8305. Are you well advised as to that?—Yes.

8306–7. But if the death register proves that a larger proportion of men who are not miners, and who die of consumption, die between the ages of 20 and 30, should you say that that registration was incorrect?—No.

8308. There are but few I suppose who are not miners?— There are a great many; they are generally fishermen here.

8309. Is not disease of the lungs which is fatal among men who are not miners most commonly so among young men?—Yes.

8310. If the death register shows that that is so, are we to infer that that is incorrect?—You meet with more consumption in females than in males, and very frequently between those ages.

8311. (*Mr. St. Aubyn.*) You have stated that the miner is less able to bear up against these complaints than other classes, because he is not so strong?—Yes, the miners generally work longer than they ought to do, and by that means they undermine their constitutions, and in consequence of that they give way much earlier than others do.

8312. Referring to their means of subsistence, do you think that they live worse or better than other classes?—They live, when they are capable of getting employment, pretty fairly.

8313. As a general rule, does the miner live as well as the common agricultural labourer, or better or worse?—I think he does. I think it is much the same.

8314. Does not the miner liver rather better?—No, not from what I have seen among the agriculturists and among the miners; I think that they live nearly the same.

8315. How many men do you attend to now in the mines?—To about 400 or 500, but I do not know exactly the number of men.

8316. How many sick persons are you looking after now who are connected with mines?— Not one.

8317. When you attended to the Gew Mines did you find that the men there suffered from miners' complaint more than they do now?—Yes.

8318. You said, I think, that it was chiefly owing to bad ventilation?—Yes.

8319. Were those mines deep mines?—It was rather a deep one.

8320. Do you think that that complaint was at all aggravated by the miners climbing up the ladders, or that it was caused entirely by bad ventilation?—I think by bad ventilation.

8321. Do you think that the climbing had nothing to do with it?—Not so much as the want of ventilation.

8322. Had the climbing, in your opinion, anything to do with it?—Certainly it had in one sense; from the want of ventilation the power of the men was weakened, and being weaker, climbing in that condition depressed their powers very much.

8323. Do you think that the climbing up ladders has any effect on the heart?—It naturally tends to increase the action of the heart by depressing the power, and they are obliged to use more effort.

8324. Do you think that the men whom you attended, and whom you stated suffered from miners' complaint at the Gew Mines, would have been in a better condition than they were if a man-engine had been used instead of ladders?—Certainly.

8325. In your opinion the lives of the miners are much longer now than they were 20 years ago?—Yes.

8326. Is that opinion based on statistical observations that you have yourself made?—No; but I may remark that in the early part of my life I found that miners suffered a great deal from indigestion. I stated my reasons for thinking so, and I have often done so. They, perhaps, had four miles to walk to their mine; they took their breakfast very early in the morning, and they went down underground to labour. Then not taking anything to support them or to give them strength to come up from deep mines, and having afterwards to walk home, the tone of the stomach had lost its power, and in consequence they suffered. But I saw that, and I recommended them very strongly always to take something with them underground, and after they had done their labour to eat it before they attempted to ascend, and to rest themselves for half an hour; and in consequence of that getting into general use it improved their powers very much indeed, and strengthened them. They became much more capable of ascending, and when they returned to their homes they could take their meals with much more power to digest the food; the stomach had not been kept so long unoccupied.

8327. Can you give, founded on your own personal observation, any definite opinion as to the length of the miners' lives at this time compared with the lives of the miners 20 years ago?—No, I cannot.

8328. Do you find that the miners under your charge at the present time suffer from stomach complaints?— Occasionally; but not so much as they did.

8329. Do the miners in this district eat pasties or bread and butter when they are working underground?—Generally speaking, bread and butter; sometimes they take down a pasty with them and sometimes bread and meat; but generally speaking, I observe when I go into the different places that they take bread and butter with them, and I find that they only suffer when a place is close. They drink a good deal of cold water, and very often paralyze the powers of the stomach in consequence.

8330. (*Chairman.*) You have observed when they are working in a close place that they drink cold water?—Yes; and very often they come to me complaining of pain in their stomachs.

8331. In what mine has that occurred?—In dif-

ferent mines. They generally take water, and some miners drink more than others.

8332. Are there close places in the mines to which you refer?—Not so much about here as in other mines.

8333. Are there close places in the mines about here?—I do not know that there are. I meant to say that when they get heated they very often drink cold water underground.

8334. Do you think that that is injurious to them?—Very injurious when a man is in a state of heat. It paralyses the powers of his stomach.

8335. Does the miner take the water down with him?—Sometimes; but they sometimes have as pure water underground as on the surface, especially in the tin mines.

8336. (*Mr. Kendall.*) Can you tell whether that heat to which you have referred arises from hard work or from the close ends?—It is from hard work generally.

8337. (*Chairman.*) You have stated that in your opinion the copper mines are more unhealthy than the tin mines on account of the greater quantity of arsenic?—Yes, there is more heat.

8338. But there is arsenic also in the tin mines, is there not?—Yes; but it is more in the stone. It is not so much in the tin mines as in the copper mines.

8339. Are the copper mines more unhealthy than the tin mines on account of the heat or the arsenic?—There is the dust in breaking in close places, it being so hot; the dust rises, and the arsenic will rise from it.

8340. Have you analysed the expectoration of any miners to see whether there was arsenic in it?—No.

8341. (*Mr. Holland.*) What effect do you suppose the arsenic produces?—It produces sore gums and dreadful blotches all over the body when a man has worked in copper mines.

8342. Have you observed among them sore eyes?—No.

8343. Any irritation of the nostrils?—Yes, very much so, very often.

8344. Is any skin disease produced?—Yes; and gatherings and blotches.

The witness withdrew.

Captain Richard James examined.

8345. (*Chairman.*) Of what mines have you charge?—I manage three mines more especially. The names of the three are Wheal Margery, Trelyon Consols, and East Wheal Margaret.

8346. Which is the largest and deepest mine of the three?—Wheal Margery.

8347. How many men are there employed underground at Wheal Margery?—At present there are about 90.

8348. Will you be kind enough to state the number that is employed at each of the other mines?—There are about 60 employed in Trelyon Consols, and 74 at East Wheal Margaret.

8349. Do those numbers include both men and boys?—Yes; employed underground.

8350. What is the depth of Wheal Margery from the surface?—120 fathoms.

8351. How do the men ascend and descend at that mine?—By ladders.

8352. What is the pitch of the ladders?—The first is 20 fathoms perpendicular, and the remainder about two feet and a half in a fathom.

8353. Are the bars of the ladders 10 or 12 inches apart?—They are 11 inches apart with us, but they vary very much. We do not see many ladders now 12 inches apart; those are the old style.

8354. Do you think there is any advantage in having the bars less than 12 inches apart?—I think so. It seems a little contrary to begin with, but after they get used to it they can climb easily.

8355. Have you worked underground yourself?—Yes. I worked in 20 different mines when I was a working miner and among every sort of mining.

8356. I suppose while you were a working miner you occasionally worked in close ends?—Yes.

8357. Did you ever suffer from working in those close ends?—Only just temporary; just for a month. I got choked or puffed up, but I never felt anything afterwards.

8358. At the time you felt puffed up or chok e d up?—Yes.

8359. Was your head at all affected?—Not at all.

8360. Did the breathing of the air in the close ends affect your climbing?—Yes, we breathed more short at the time.

8361. How do you discover that an e. d gets close?—By the candles as soon as by anything.

8362. Do you discover it by the candles as soon as by your own feelings?—Sooner. The candle will decline before we can feel it, except we work very hard, and then we can discover it; we begin to breathe very short when working in a close place more than when working in a place where there is plenty of air.

8363. Did any of the men who were working in the same pair with you suffer in the same way?—No; we were only two. We worked in one particular close place, we really did in those days; but we do not see anything like it nowadays. We worked when we kept our candle some 12 to 18 feet behind us.

8364. How far was that place from any shaft or winze?—It was not very far from the surface; it was called the 20 fathom level. I do not remember any accident there. We were in about 100 fathoms with no winze; it was what we call in these days a trial end; there was nothing done in that part of the mine. They intended to drive an end through a virgin piece of ground.

8365. You think you may have a close end in a shallow level as well as in a deep level?—Yes.

8366. How far was this end driven from the shaft?—100 fathoms.

8367. Was it following the lode?—Yes.

8368. How long were you able to work in that place, how many months or weeks?—I worked there for some two years.

8369. During all that time did you burn a candle?—During the whole of it, little or much. As it got further off it was so bad that we could not see it for days together. It depended upon the wind at the surface. With a north wind it was keener air, and we could work then better than with a south or south-west wind. For days together we could not then carry a candle within 20 fathoms of it.

8370. I suppose you were paid highly for working in that place?—No, it was very poor time then amongst the miners. It was in the neighbourhood of Helston in a lead mine called Wheal Rose near the Looe Pool.

8371. Is that mine being worked now?—No; it was very poor times with the miners, and we were driven to great shifts in those days. I am speaking now of about 15 years ago.

8372. How long have you been captain or manager of mines?—Now I have been a captain between 11 and 12 years

8373. Before that had you been working in any other mines where there was poor air?—Not so bad as what I have described; but in some very close places.

8374. Have you ever managed any other mines than those you have enumerated?—Yes; I managed one in St Just and one called the Durlo in Towednack a little while, and I managed one other in Towednack called the Georgia Consols.

8375. Are those mines being worked now?—Not the Georgia Consols, but the Durlo is. There is another called South Speed in Lelant.

ST. IVES.

Capt. R. James.

2 August 1862.

8376. Were there any poor ends in those mines?—No.

8377. In St. Just were there poor ends in those mines?—No, there were not.

8378. How long does the smoke take to clear away from any end in the mines with which you are now connected?—There are two ends in which we have driven more extensively than in the others, and the smoke would lie there before we stopped them a good part of one hour before the men could get in.

8379. At the present time are you not driving in those ends?—No.

8380. How long will the smoke take to clear away in any one end now?—In the closest end that we have we can go in to work in 20 minutes.

8381. How far is that from a winze?—About 10 fathoms from a winze; about 40 fathoms from a shaft.

8382. Is there plenty of air there?—Yes.

8383. (*Mr. Holland.*) Is that the worst end that you have?—Yes.

8384. (*Chairman.*) The worst in any one of the three mines you have mentioned?—Yes; the one that I am now speaking of I think would be a fair sample for either of the others. The others are better in many things than this one is,—this is Wheal Margery.

8385. What do the men pay for candles?—9*d.* per pound.

8386. What quantity of candles are allowed to each man?—2 lbs. a week.

8387. And no more?—No.

8388. What do they pay for the powder?—They pay 9*d.* a pound for the powder.

8389. Since you have been managing the mines you have mentioned, have any accidents occurred from blasting the ore within the last five years?—Yes; in Trelyon Consols we have had one accident only.

8390. Were you able to ascertain how that occurred?—Yes. I do not know how it missed, but the hole missed fire, and the man went to bore it out with a borer, and he actually beat away with the borer as if he was boring, and in doing that the powder exploded, and it carried off his arm.

8391. How do they fill in the powder, with a tamping rod, or do you require them to use any particular tamping rod?—We profess to have to do so. We lay down this rule in the mine, that any man known to be injured by an explosion who has not used a wooden rod is entitled to no pay,—that is our rule,—that is, when putting in the powder and packing it.

8392. If after that notice a miner uses an iron bar he is not entitled to any relief?—No.

8393. Have you ever seen any other bar used?—Yes; I have seen the copper bar; they are put up to the iron bar. They have a piece of the end of it that is copper, and I have seen fire come from that; a kind of blue fire, something like brimstone.

8394. (*Mr. Davey.*) Was that from the copper or from the alloy?—No; it was had for copper. We understood it to be copper.

8395. (*Mr. Holland.*) You do not think it was the shank of the tool that caused it?—No; we tried it outside the hole to see if it would strike fire, and it was a kind of dead blue fire.

8396. (*Chairman.*) Do you use cartridges in the mines with which you are connected?—No; but we have done.

8397. Does an accident ever happen in consequence of the powder lying round the edges of the hole not being properly swabbed out?—Not generally; that was in days gone by more than now. We always take care to clean it out with this wooden rod; we dip it in water and wipe out the hole with the en of it.

8398. If that precaution was neglected there might be danger?—I believe that was the cause formerly of many of these accidents. I do not know of one that has happened really in a fair way of tamping up in any of the mines that I am connected with.

8399. What do the men contribute to the club?—With us the girls pay 3*d.* for the doctor only; they are not entitled to the club. A boy earning below 20*s.* pays nothing; but if he is earning 20*s.* he pays 6*d.*, and the men pay 1*s.* to the doctor and the club.

8400. Do you keep any account of the club money?—Yes.

8401. Do you balance the account every year?—I really do not know; that is the purser's business. All we do if any man is injured or sick is this, if that man is injured or is ill so many days, for every day he gets 1*s.*, and the purser keeps an account of it.

8402. If a man were sick would he receive anything?—Yes; we have a clause in our rules that a man, unless he should show a visible hurt, has no real claim; but it is left to the discretion of the purser and the agent. And if a man is taken ill we allow him as much as the circumstances may enable us to allow. If he dies we bury him, and support his widow, or contribute to the support of his children afterwards.

8403-4. (*Mr. Davey.*) For howlong do you do that?—While the mine continues the club will support that. I know one case of a man who worked in the Providence Mines for many years, and he was worn out. He was out to lodgings and his wife died, and the woman with whom he lodged could not support him for the 30*s.* a month, or 1*s.* a day, and he went to the Union; he died there, and all expenses, including funeral, were repaid the Union, amounting to 2*l.* 5*s.* 8*d.*

8405. (*Chairman.*) Under Mr. Higgs's management, do you think that they are a better conducted class of men?—Yes, I am sure that they are.

8406. (*Mr. Holland.*) Is such an act of liberality and kindness on the part of Mr. Higgs as you have just mentioned of common occurrence?—I do not think it is so general as it is with him.

8407. I presume that it was thought a very liberal act?—Yes it was.

8408. (*Chairman.*) That is the way in which the mines under Mr. Higgs's charge are conducted?—Yes it is; it was thought by others very liberal to pay the Union expenses.

8409. How many boilers have you under your charge in the different mines you have named?—There are three in Wheal Margery, and one in each of the other two mines, they are small engines except in Wheal Margery, and there we have two for the pumping engine, and one for the steam whim.

8410. How often do you clean the boilers out?—We clean the boilers out really once a month, but we cleanse them throughout once in two months, once a month we take out the tap in the bottom of the boiler, and then all that is in it rushes out, and then at the end of two months we cleanse them altogether and get into the boilers and clean out the flues by the side of the boilers.

8411. Do you test the boilers by any means?—No, we have no means of testing them.

8412. Cannot you test a boiler with cold water?—Yes, but we never did; we examine a boiler to see if everything is right.

8413. Have the men any means of ascertaining whether there is an insufficient quantity of water in the boiler?—No other means except the two gauge cocks, the bottom one is four inches above the fire take, and the top one is about four inches over that again, so that if we have water at the bottom cock, it is then four inches over the tube; in one boiler in Wheal Margery we have really eight inches there, which is rather unusual.

8414. (*Mr. Holland*) How long would that be evaporating?—About two hours We have got a rule by which we never allow a man, whether he is by night or by day, supposing another man's core is up this morning, to go in unless he tries the cocks and finds that the feed is up flush to the cocks, and if it is not he has to come then and give us the result, and say why he does not take charge of his work: we do not let him take charge unless he finds that the feed is up to the proper place.

8415. Is that the rule strictly observed in the mine?—Yes.

8416. How do you enforce it?—We see for ourselves that it is so.

8417. You are able to enforce that rule effectually? We do it pretty well. I do not mean to say that we do see it every morning, but we go when they do not think that we are coming, and we take care to lay that rule down carefully.

8418. (*Chairman.*) Do you think that the miners are satisfied with the medical attendance that they have?—Yes.

8419. Who is the medical attendant that is employed?—The last witness is one and Dr. Rosewall is another; we have two in the same mine, so that if one is out or away from home, we lay claim to the other, and if it is an important case we send for both of them.

8420. I suppose they only attend to the miners and not to their families?—No.

8421. (*Mr. Holland.*) Have you worked in a mine where there has been only one doctor?—Yes.

8422. Does it give more satisfaction to the men when there are two medical attendants?—Yes.

8423. (*Chairman.*) The doctor is required to attend in the case of any illness that a miner may have, whatever it may be?—Yes, that is, to the man himself, and not to his family.

8424. (*Mr. Holland.*) You were speaking a short time back of working 100 fathoms in advance where there was very hot air; was not the cost of such work much increased by the want of good air?—Yes, it was; but they could not very well bring air to it without expense.

8425. About how much per fathom was the cost of working increased by want of good air?—I do not know, perhaps it would really turn out to be one quarter part; I got 40*s.* for driving that close end, and I could very well have done it for 30*s.* if I had had good air; but that is the only very bad case that I know of.

8426. In a case where the powder smoke hangs about for an hour, and in another where it is cleared away in a quarter of an hour, there must be a great difference must there not in the profit obtained from the working?—Not so much, as the men bore the number of holes for one core and fire them on leaving work.

8427. (*Mr. St Aubyn.*) In answer to a question put to you by the chairman with respect so some mines in Towednack, which are not now working, you said there were no close ends in those mines?—Yes.

8428. You also stated that you had seen a tamping rod with copper at the end of it strike blue fire?—Yes, I said that from my own experience.

8429. Is it not possible that that might have occurred from that part of the rod which was made of iron striking against the sides of the hole?—It was not tried in a hole, but it was tried outside in order to see whether it would strike fire; it was the understanding that it would not strike fire, but we tried it against some of the most fiery stones, to see whether the copper would strike fire, and we saw little dull sparks.

8430. Do you think that they would have ignited gunpowder?—Yes, I think there was fire enough for that.

8431. You believe that those sparks were produced by the contact of the copper with the stone?—Yes, it was at the bottom that we tried purposely.

8432. (*Mr. Kendall.*) The sparks were not of the same colour as those which are produced by iron?—No, they were little blue sparks.

8433. (*Mr. Holland.*) Did it look at all like the sort of blueish flash that is produced by the rubbing of two fire stones together?—Yes.

8434. (*Mr. Davey.*) You have stated that you drove a level for 100 fathoms without any artificial ventilation?—Yes.

8435. And that it was only 20 fathoms from the surface?—About 20 fathoms; we called it the 20 fathom level.

8436. How long generally could you work, about two thirds of the time, or scarcely so much?—We were for two days sometimes when we could not go near the place.

8437. Who was the agent at that time?—Captain Michael Morgan.

8438. He was considered an able man, was he not?—Yes.

8439. If you did the same thing now, what should you consider the system of working the mine to be?—I should not consider it very good.

8440. Do not you know that in sinking that 20 fathoms, as you would do in copper mines would be to ventilate the whole of that piece of ground, and then drive another 20 fathoms?—Yes.

8441. Is it very unusual to drive a level to the extent you have described without sinking a shaft if you had no winzes?—Yes, it is quite unusual. I said that it was a singular case, and the most extraordinary one that I ever saw in my experience. I do not mean to say that that is the general rule.

8442. Was it not a thing that would never be done now under the improved system of mining?—I have not seen such a thing done for many years.

8443. (*Mr. Kendall.*) How far was the level driven in before you found the air getting very bad?—We found it bad for the last 20 fathoms.

8444. It was not very comfortable after the first 50?—No, it was getting close.

8445. If you had gone to the expense of sinking a shaft at the end of the 50 fathoms, you would have saved a great deal of money by it, would you not?—Yes.

8446. How long were you driving the last 50 fathoms?—We drove about four or five fathoms a month.

8447. At what price was the work done?—The highest price was two guineas.

8448. You were working in a loose friable rock, were you not?—Yes.

8449. And therefore it would have been much easier to sink, as the cost of a shaft would have been very moderate?—Yes; they could have sunk five fathoms a month I suppose, and could have got down there in about four months.

8450. How may men were employed there?—Only two.

8451. Did only one of them suffer?—Neither of them suffered.

8452. You stated that you felt choked up?—Yes, just at the time, but not afterwards.

8453. How long were you working there, nearly two years?—Nearly about that time; it is many years ago now.

8454. What age are you now?—43.

8455. How long did you work as a miner?—I worked from the age of 7 up to 31.

8456. Ever since that have you been an agent?—Yes.

8457. Have you worked in 20 different mines?—Yes.

8458. How is your health now?—Very good.

8459. Do you generally meet anywhere with stronger men or men in better health than yourself?—I do not see many; besides that end, I have not worked six months in bad air.

8460. Did you ever get any start at all in any of the mines?—Not very heavy ones; sometimes 20*l.* or 30*l.*

8461. Have you known many men who have got starts?—Yes.

8462. When they get a start, is permission given to them to work as many hours as they like?—Yes.

8463. And I suppose they do work very hard at those times?—Yes.

8464. How many hours do they work upon those occasions?—Very often 12 hours, not often less than 12 hours.

8465. When they get a start, do they not over exert themselves?—Some men do; most men do, I suppose; but they take in a great deal of eating and drinking to keep it up.

8466. Have you ever known a case in which their

St. Ives.
Capt. R. James.
2 August 1862.

food and drink have been taken down to them, and the miners have stayed underground ?—Yes.

8467. (*Mr. Holland.*) Have they stayed underground for a whole week ?—No, only for 12 hours, and some refreshment has been taken down to them in the shape of beer and spirits.

8468. (*Mr. Kendall.*) From your experience, when should you say that the miners worked the hardest ; when they are earning plenty of money, and in order to make more, or when they have got a very moderate take, and it requires pretty hard work to make up fair wages ; in other words, are they not generally lazy when they have got a poorish take ?—Yes ; we allow the miners to get about 3*l.* If we give them a bargain to get 4*l.* they have actually got 5*l.* or 6*l.* by working extra ; but if we give them a bargain to get 2*l.* instead of 3*l.*, they will not get more than 30*s.*

The witness withdrew.

Mr. John Nancarrow examined.

Mr. J. Nancarrow.

8469. (*Chairman.*) What mine have you the management of at the present time ?—St. Ives Consols.

8470. Do you manage any other mine ? — East Treskerby in the Chacewater district.

8471. What does the St. Ives Consols produce ?—Tin and a little copper, very little of it now.

8472. What is the depth of the lowest level from the surface ?—197 fathoms from the surface ; we call it 200.

8473. By what means do the men at that mine ascend and descend ?—By ladders.

8474. How many men have you working under ground ?—182 men and boys.

8475. How many men are employed above ground ?—Our men, boys, and girls altogether will amount to 360.

8476. At what levels are you working now ?—We are working at the bottom at the 167 and the 177, and in every level up to 97. We are working at the 87, and up to the 67 and 47.

8477. Are there any close ends in which the men are working ?—There are none in which a candle will not burn very well, and it will burn very well. We have seven shafts.

8478. Have you any other means of testing the state of the air besides the burning of the candle ?—No.

8479. Have you no artificial means of ventilation ?—No, we do not require any ; we only just put a soller into the bottom of a level.

8480. You do that ?—Yes.

8481. Have you any levels in which a soller has been placed ?—Yes, one.

8482. Is the air not quite so good in that level ?—It is warm.

8483. Which level is that ?—The 170.

8484. Do you know at all what the heat is in that level ?—No, we never tested it,

8485. How long does the smoke hang about in the level in which the soller has been placed ?—It might stay for an hour or two. We only work it by two cores out of four. We have one idle between, so that it is completely cleared out before the other comes.

8486. What is your object in doing that ?—In order that the men may be able to work it better.

8487. You think that if a fresh core went down to relieve the other, the state of the air in the level would not be so good as if it were dealt with as you have described ?—Certainly not.

8488. Therefore in order that the air may become improved by the men being out of the level you leave it for a short time to be ventilated ?—Yes ; in fact it is completely cleared out.

8489. Have any of your miners ever suffered from working below ?—I do not know that they have ; they do not complain.

8490. Do you know of any men who have suffered from miners' disease ? — No ; not one. The men work six hours in the end I have referred to.

8491. Two cores ?—Yes ; but they leave six hours between ; but that is the only place of that kind.

8492. What quantity of candles do you allow to a man ?—2 lbs. a week.

8493. Although they only work for a shorter time, do you allow them the full quantity ?—Yes ; they work six days one week and five the other generally, but that is the only case in which they work in that way ; eight hours is the regular core.

8494 What do the miners pay for the candles ?—10*d.* a pound.

8495. How much do they pay for the powder ?—9*d.* a pound.

8496. What is the cost price of the candles ? — About 6*s.* for one dozen pounds.

8497. What is the object of charging the miners 10*d.* a pound ?—As to the object I am not prepared to say. It was the custom established in the mine before I came there ; I have only had the management of it for two years and a half, or barely that. I saw no reason to alter it.

8498. What is the cost of the powder ?—It varies in price ; sometimes it is 7*d.* sometimes it is more and sometimes it is less ; now it is 6*d.* a pound exactly.

8499. What do the miners contribute to the club ?—They pay 6*d.* a man per month.

8500. Do the surface men also pay ?—Yes. The surface men pay to the club and to the doctor too ; every man does.

8501. Do the women contribute anything ?—No ; —they pay nothing.

8502 What do the men pay to the doctor ?—6*d*

8503. Do they pay anything to the barber ?—No. There is no barber.

8504. How are the doctors appointed ?—It is generally done at a general meeting of the adventurers.

8505. How many doctors are there generally ?—There is only one here, but there are sometimes two, and sometimes three.

8506. What is the name of the doctor you have referred to ?—Dr. Young. He lives in the town, and has been doctor of the mine for many years.

8507. Are the men all satisfied with one doctor ?—There is no dissatisfaction expressed.

8508. Do you know whether they go to any other doctor ?—I do not know ; they may have gone to another doctor. We have very little sickness. I have not heard any particular remark made about it.

8509. Do you subscribe to the club ?—No.

8510. Do the agents not subscribe ?—No. In some mines they pay to the doctor, and in other places they provide themselves.

8511. Then the doctor does not attend you, or your family ?—No ; it has been so in some cases where we did pay for the doctor, but not here.

8512. Do you pay the miners, or does the purser pay them ? — The purser pays the men working under ground for two or four or six ; the pairs are paid together ; but generally in a mine every single man or boy is paid separately.

8513. (*Mr. Holland.*) Are the pairs paid in such money that they can easily divide it amongst them ?—They are paid in bank notes generally, and sometimes in sovereigns.

8514. Would it not be a great advantage and convenience to pay them in small money, so that they could divide it amongst themselves without having to go to a public house for change ?—It might be ; but the greater part of them do not go near any public house at all.

8515. Where do they obtain change ?—I do not know where they get it.

8516. (*Chairman.*) How many boilers have you working ?—We have six boilers working.

8517. How often do you clean them out?—Every two or three months.

8518. Is there no fixed time for cleaning them out?—No; that is at the option of the agents, but we do not allow it to go beyond three months, except that we have occasionally at one engine gone as far as four months; but our water there is pure spring water, and in fact the men drink it under ground; they carry it down with them; they actually take the water that is brought into the dry for them to wash with down with them into the mine. There is no corrosive quality in it.

8519. When you clean a boiler out do you examine it to see whether it is in a sound state?—Yes, we examine it.

8520. Are the rivets carefully looked after?—Yes, we look at them occasionally; but our boilers I suppose have been worked for 30 years, and they do not seem to corrode at all.

8521. There is no regular time fixed for examining them?—No; I do not know that there is.

8522. Do the men change in the boiler house?—No; all the men in the mine are collected in the dry.

8523. Do the women work under cover?—Yes.

8524. Have they a place to which they can go to take their meals?—Yes; there are places in connexion with each of the dressing floors.

8525. (*Mr. Holland.*) Is the strength of the boiler tested at any regular interval?—No; it has not been tested since I have been there.

8526. Are the boilers provided with one or two safety valves?—With one.

8527. Is that considered safe in this part of the world?—Yes.

8528. (*Chairman.*) Has no accident ever occurred from the bursting of a boiler in your mines?—No; there has not been one accident of the kind during 45 years that I know of. The water is easy in this neighbourhood, and our engines are not forced; I mean that we have a small quantity to pump.

8529. Have you ever heard of any boiler accident having taken place in this neighbourhood?—I have heard of none since I have been here.

8530. Have you had the management of mines in any other parts of Cornwall?—Yes; I have at Great Wheal Busy for a time.

8531. Were you at that mine when an accident happened there?—No; there was no bursting of a boiler while I was there. I never had a boiler burst in any mine that I have been in.

8532. You have always taken care to examine them well?—Yes; and another thing that I always pay particular attention to is to see that the water is got into the boilers as pure as possible, except in one case where we had to mix soft clay with the water, it was so uncommonly keen.

8533. In what mine was that?—That was at Wheal Busy for a little time.

8534. The water at Wheal Busy is very bad, is it, for the boilers?—Yes.

8535. While at Wheal Busy no bursting of boilers took place?—No; nor at any other mine that I was ever at.

8536. (*Mr. Holland.*) Is the water used at Wheal Busy an acid water?—Yes.

8537. Where did you get the clay from that you spoke of?—In the mine. It was a questionable matter what was best to be done with the water,—my predecessor filtered the water, and extracted all the sediment from it, and thereby it had a greater power to act upon the iron.

8538. You are the manager of another mine in the east, are you not?—Yes; East Treskerby, near North Wheal Busy about a mile away from North Wheal Busy.

8539. What number of men are employed there?—Only 14.

8540. Is there more than one shaft there?—There are two shafts.

8541. What kind of work are they now doing?—We are sinking one of the shafts and driving the two levels.

8542. How often to you visit that mine?—Once a week; there is a captain of the mine there every day and all days.

8543. In driving the levels is there any poor air there, do you think, or any close end?—No; it will get close as we get further off. We are now in about 30 fathoms and the air is not bad.

8544. How far are you driving now from a shaft?—We are 30 fathoms from a shaft.

8545 How far do you think you will be able to drive?—I cannot tell; we may drive 10 fathoms further; and if we find that the air is failing we shall out down a winze or have a waterfall, or else attach a machine to the engine.

8546. Have you got machinery ready for it?—No; we have not.

8547. How will you ascertain when that becomes necessary?—We are driving towards the lode; we cannot tell the exact distance it has not been seen over this place at all; this is 40 fathoms from the surface, and we cannot tell what our future plan of operation will be.

8548. How will you know when it becomes necessary to introduce your waterfall?—When the smoke will lie badly in the level, and when the candle will not burn properly.

8549. Until then you consider that the air is good?—Yes, generally; there have been cases in which there is a sort of damp settles; but I have never seen anything of the kind in this mine, nor in the other mine.

The witness withdrew.

Captain Matthew Curnow examined.

8550. (*Chairman.*) Of what mine have the management at the present time?—Wheal Mary in Lelant.

8551. Is that the only mine of which you have charge now?—Yes.

8552. How many men are working there underground?—Somewhere about 110 I think.

8553. How do the men come up and go down the mine?—By ladders.

8554. What is the deepest level in that mine?—The deepest level in 160 fathoms under the adit.

8555. What is the heat of that level?—I do not know, as it is quite cold there; there is a breeze of wind there, and the men are glad to stand in it sometimes.

8556. How many shafts are there?—We have got three shafts; but we have got but two working ones; where the men ascend and descend.

8557. Are you driving any level where the air is at all close?—Not one in the mine; not to say close.

8558. What do you understand by the word "close"?—Short of air, or not ventilation enough; that is what I call closeness.

8559. What do you understand by the term "poor air"?—That is where the candle will not burn without leaning it to its side. I have worked in that many times, scores of times, for years.

8560. Did you suffer from that at all?—Very little; it was cast out again; I felt a little from it once, but it passed off again.

8561. Have you worked several times in places where the candle would not burn?—I have worked in as bad air as any man in the country.

8562. How did you feel under such circumstances?—I felt a shortness of breath.

8563. Did you suffer from any affection of the stomach?—No.

8564. Was your appetite impaired?—Yes; but we took a little medicine to get all right again.

8565. When you were working in poor air, did you

St. Ives.
Capt. M. Curnow.
2 August 1862.

feel the effects of it afterwards in climbing the ladders ?—Yes ; I felt a little stupefied.

8566. Was your head at all affected ?—Yes ; I was not lively.

8567. Did any of the other men working in the same core with you suffer from the same cause ?—Yes ; some of them died of it.

8568. Are there none living now who worked with you at that time ?—No ; not one of the pair. I am the only man that is living ; but they were much elder men than I was at that time ; I was young, about 19 or 20.

8569. At what age did they die ?—Every one of them lived, I should say, until they were between 60 and 70.

8570. Did they work underground all that time ?—Some of them worked on to the last.

8571. Were they not affected by it ?—Not a bit ; it depends upon the constitution ; some men are stronger than others.

8572. You have, I presume, heard of what is called miners' disease ?—Yes.

8573. Have you ever seen any case of that ?—Yes.

8574. Do you know any men who are at the present time suffering from miners' disease ?—No ; it is very rare now ; there are better means used in ventilating mines than there used to be.

8575. What are the means that are now used for ventilation ?—Cutting open more ground.

8576. Do you mean that the more the mines are extended the better the ventilation is ?—Yes ; the more it is cut up and opened.

8577. A new mine is therefore likely to be not so well ventilated as an old one ?—Yes ; because they have but one shaft generally ; and there is one thing that there is better ventilation in the copper mines where they work shallow than what there is in the deep mines in granite, as they can sink some four fathoms for one in killas ; in sinking one fathom in granite they can open four or five in the killas.

8578. Are there any mines in which we could see a place where the air is poor ?—Not to my knowledge in our locality.

8579. I suppose there are such places in other deep mines ?—Yes ; I have heard a deal of it, but I have not seen it.

8580 In what district were you employed when you were working in poor air ?—I was working at about 70 from the surface and 50 fathoms from the shaft.

8581. What district was that in ?—It was about three mile from here ; on the south, in the parish of Towednack.

8582. With regard to the rules to be observed n mines, are they printed rules ?—What do the men pay for candles ?—They pay 9*d.* a pound.

8583. Do you limit them to a certain quantity ?—Yes, they are limited to 2 lbs. a week per man.

8584. How is the mine worked—how many men in a pair ?—There are two in some places, and sometimes they work more—where it is set to them in breaking ground, they almost always make it two.

8585. A core consists of six men, does it not ?—A pair consists of six men ; sometimes the pairs are not more than two, sometimes four, and sometimes six.

8586. How many hours a day do they work ?—From six to seven hours.

8587. Then there would be three pairs employed in the course of 24 hours ?—Yes, where there are six in a pair.

8588. Do you think that the plan in St. Just of one man working is better than two men ?—Not for the borers ; a man must use more strength to beat the work by himself as compared with two men.

8589. Do you know what the cost price of the candles is ?—I think we pay 6*s.* 6*d.* or 6*s.* for a dozen pounds, but I am not clear upon that.

8590. What do you charge the miners for powder ?—We charge them 8*d.* a pound.

8591. Do you use any kind of patent powder, or the common powder ?—We use the common powder that is made here in the county.

8592. What do the men contribute to the club ?—6*d.* for club, and 6*d.* for doctor.

8593. The club money is to provide only for visible accidents, is it not ?—Yes ; if we know that a man falls and injures himself.

8594. It is not a club to provide for sickness ?—No, unless a man is sick, and is laid up at any time, it is thought a kind of charity to support him from the club rather than that he should come to any place of charity else.

8595. Is any account kept of the club money ?—Yes, but our purser keeps it ; we have not got it opened in our books.

8596. Does the purser lay it open in his accounts to the shareholders ?—Yes, it is kept as a stock for the club. I do not know, but I should think it was the men's property ; I should say so.

8597. Is an account kept of it for the men, or do they know anything about the state of the accounts ?—No ; no other than that if any man is injured or sick, and they think proper to relieve him.

8598. Do you subscribe to that club ?—Yes, I have been working in this mine for 28 years.

8599. You are now the manager of it ?—I am agent.

8600. Have you been agent for 28 years ?—I have been agent for some 16 or 17 years.

8601. Do you always pay to the club ?—I should say that I do not think the agents do.

8602. But you do, do you not ?—I have for many years, when I was working.

8603. But not now as manager ?—I am not manager, our manager is not able to come, and I am here to represent him.

8604. Then what are you now ?—I am here underground agent.

8605. You do not yourself contribute to the club now ?—No, I reckon that that is a privilege given to the agents by the adventurers.

8606. If any accident happened to you you would be entitled to something from the adventurers ?—Yes, I suppose so.

8607. Have you one doctor or two at your mine ?—We have two doctors.

8608. By whom are they appointed ?—By the men, that has been so for some years gone by, and that still stands.

8609. In your opinion is that a good plan ?—Yes, it is more pleasing to the men.

8610. Is that the general practice ?—No, there is a little more interest taken in that in our county in places.

8611. I suppose the doctors are generally chosen by a canvass ?—Yes ; I have attended meetings where, in putting on mines we have taken up shares to carry on a mine, and that has been canvassed before the adventurers and carried there, and then the labouring men must take whoever is fixed on to attend them ; but ours was carried by a majority of the men.

8612. I suppose the same principle could be pursued in case there was a change of doctors ?—Yes.

8613. Do you think that that is a better system than that the doctors should be appointed by the adventurers ?—Yes, a great deal better.

8614. You consider the club money to belong to the miners ?—Yes, if the men were to turn out, and were to say, what is to become of our club money, we should say we have the money as support money.

8615. But who looks after it ?—The books would get overhauled.

8616. Does the purser present any account to the men ?—No, I never heard that broached to the purser at all.

8617. Then you would not know how the account stood ?—I heard a little while ago a fellow agent say to a purser, "I suppose our fund is pretty stocky," and he said "It is right enough yet." I suppose we must have the money, but it would be better to have

ST. IVES.

Capt. M. Curnow.

2 August 1862.

an account rendered to the men, although it is not the general rule in the mine.

8618. Generally speaking there is no account kept of the club money?—I do not think there is anywhere; I believe it is more supposed to be so than anything else.

8619. If no accidents happen in a mine, the sums which the men contribute to the club must amount to something considerable?—Yes they must.

8620. Suppose that a mine were to be abandoned what would become of that money?—That is a question that I cannot answer, because I never worked in a mine that came to that, nor ever heard tell of the thing being brought in.

8621–2. Why is the charge made to the miners for candles, not only higher than the cost price, but higher than the market price?—It is the rule, and another thing is in order to keep the men so that they shall not run themselves to too much expense; it is different to pay for a thing at a dear price to what it is in coming and taking it away at a cheap price; if I take up a thing that I pay for heavily, I must take care of it.

8623. But suppose you only allowed a certain quantity?—What is allowed them is considered enough.

8624. Therefore you would not allow them more if they only paid 7*d.* a pound for the candles instead of 9*d.*?—No more than we should if they paid no more than 6*d.*

8625. Beyond the cost price there is a profit made upon the candles?—Yes

8626. And the same on the powder?—Yes, and that is to make the miners take care of all those things.

8627. But still the men would always have to pay for them as long as they were not supplied to them below cost price?—Yes, but if a man could get them for 4*d.* a pound he would not be so nice about it.

8628. How long did you work under ground as a miner?—For more than 30 years.

8629. How old are you now?—I am in my 50th year.

8630. Have you never suffered in your health from working under ground?—No.

8631. But have others to your knowledge?—Yes, the men I have worked with; I have worked along with men who could not work so long as I could. I could work 24 hours where they worked 12.

8632–3. Do you know any men who are alive who have suffered from working in the mines?—It is a very rare thing with us anywhere in the neighbourhood; during the last 10 or 15 years the mines have been getting better ventilated, and the health of the men is more studied now than it was 30 years ago; they study the health of the men, and one man thinks more of another.

8634. The comfort of the men is attended to in your mine?—Yes, there is a stream of beautiful water that is caried down into the mine for the men to drink.

8635. Could not that stream if necessary be made use of for the purpose of ventilating the mine?—From the ventilation our men do feel great benefit.

8636. But do you not use this water for ventilating the mine at all?—No, it is for drink for the benefit of the men; it is good for their health when eating their morsel.

The witness withdrew.

Adjourned to Camborne on Tuesday next at half-past 10 o'clock.

CAMBORNE

Tuesday, 5th August, 1862.

PRESENT:

The Right Honourable Lord KINNAIRD, K.T.
RICHARD DAVEY, Esq., M.P.
NICHOLAS KENDALL, Esq., M.P.
JOHN ST. AUBYN, Esq., M.P.
P. H. HOLLAND, Esq.

The Right Honourable Lord KINNAIRD, K.T., in the Chair.

Captain CHARLES THOMAS examined.

Capt. C. Thomas.

5 August 1862.

8637. (*Chairman.*) Will you be good enough to state what mines you manage?—Dolcoath mine, Cook's Kitchen, Stray Park, West Wheal Seton, West Wheal Frances, and Calvadnack.

8638. What is the produce of the Dolcoath mine chiefly?—Tin principally, and a little copper.

8639. What is the produce of Cook's Kitchen?—Tin also.

8640. What does Stray Park produce?—Copper and tin.

8641. And West Seton?—Mainly copper; a little tin.

8642. What does West Frances produce?—Tin.

8643. And Calvadnack?—Tin.

8644. How many men are employed underground in Dolcoath mine?—I have sent in a list of the men employed at all the mines.

8645. What is the whole number of men, women, and children that are employed at all the mines you have mentioned?—The whole number of persons would be about 3,500 in the mines of which I have the superintendence.

8646. What amount of property do you think is represented by the mines of which you have charge?—The present market value I should think is about 400,000*l.*

8647. Does the return which you have sent in give the ages of the boys who are employed underground?—Yes.

8648. On the dressing floors, what is the age of the youngest children who are employed there?—There are a few at 9 years of age, but very few indeed; at the age of 10 and 11 there are a great number; there may be one or so between the age of 8 and 9, but it is a rare occurrence for any one of them to be younger than that.

8649. Is there any limit to the age at which you receive them at the dressing floors?—No; a father or mother will come and say perhaps, "I have this little child, and I do not know what to do with it; I can scarcely get bread for it, will you take it?" and we sometimes yield to that, and take the child in to do such work as it can do, but it is very light work.

8650. What are the lowest wages that they receive?—6*s.* a month is the lowest wage.

8651. Are there any evening schools established to which these children can go of an evening to receive instruction?—There are schools to which they can go in the evening; some schools, but not enough to take one tenth of them, I should think.

8652. So that many of these children have not an opportunity of obtaining any education if they go so early to work?—Not in the evening, except in the Sunday schools, and they are open to all that will come; we have sufficient room there for all the children, and a large proportion does attend the Sunday schools connected with the Church of England, the Wesleyans, and other sections of the Church; a very large proportion of them do attend.

CAMBORNE.

Capt. C. Thomas.

5 August 1862.

8653. The attendance at the day schools, I suppose, is but small?—I think that a large proportion of the children attend day schools of some kind or other until they are 9 or 10 years old; I should think seven eighths, but I am not sure about the exact number.

8654. I suppose as soon as children are capable of earning money their parents send them to work instead of sending them to school?—Yes, with but few exceptions; there are a few tributors who get on very well, and some few tut-workmen, men of power of mind and of body, who can get a little more money than the ordinary run of miners, and then they can support their families better; such as those send their children to the British School, or to the National School, until they are 12 or 13 years old—a few of them; at the age of 10 or 11 they generally leave the school.

8655. At the Dolcoath mine, what is the depth of the lowest shaft that you are working at?—From the surface it is just exactly 300 fathoms.

8656. What means are employed at that mine to enable the miners to ascend and descend?—We have a man-engine to send down the men by and pull them up again, down to 220 fathoms out of the 300.

8657. Is it a single or a double man-engine?—Single.

8658. Have you ever seen a double man-engine at work?—Yes; I have gone down into a mine, the Tresanvean mine, when it was working, (it is shut up now) with a double engine.

8659. Which of the two do you prefer?—I much prefer the single one as being safer.

8660. By the double man-engine can more men be sent down?—Yes; but not in proportion, not double as many in the same time.

8661. Is that the only mine of which you have charge in which a man-engine is employed?—No; there is a man-engine at work at Cook's Kitchen.

8662. How deep does that man-engine go down?—The man-engine there goes 190 fathoms down from the surface.

8663. What is the greatest depth of the mine?—It is 260 fathoms down to the deepest point there; but a few men only are working there now. At Dolcoath only a few are working down at the deepest point; a large number have to climb ladders for 30 or 40 or 50 fathoms, but not many for 80 fathoms; for 60 fathoms a considerable number.

8664. That is before they reach the level to which the man-engine descends?—Yes, that is true as to Cook's Kitchen as well as Dolcoath.

8665. Is the man-engine employed at Cook's Kitchen also a single one?—Yes.

8666. Will you be good enough to state to the Commissioners the depths of the other four mines?—I think that Stray Park was the next that I mentioned, and that is 250 fathoms from the surface.

8667. What is the greatest depth at West Wheal Seton?—160 fathoms from the surface.

8668. And at West Wheal Frances?—85 fathoms from the surface.

8669. And at Calvadnack?—80 fathoms from the surface.

8670. In the last-mentioned mines do the men ascend and descend by ladders?—Yes.

8671. Would it not be an advantage to have the same means of ascent and descent in these mines as in the others?—A very great advantage for Stray Park mines; not so great for West Wheal Seton, for the ladders are laid in on an angle of about 50 degrees from the horizontal, and it is not hard work to get up the ladders there.

8672. Do they follow the course of the lode?—Yes, nearly all the way—perpendicular shaft 20 or 30 fathoms from the surface—on the line of the lode, from thence to the bottom; it is not hard work there, but at Stray Park a man-engine would be very desirable.

8673. Did you ever recommend to the adventurers that a man-engine should be employed at Stray Park?—We have not got convenience for it; we are looking forward to making a communication from Stray Park mine to Dolcoath mine; both mines belong to Mr. Basset, who is lord, but the same adventurers in the one mine are not the adventurers in the other; I having the management of the two, we have our eye upon making a communication, and then to come to an arrangement, if we can, to pay from Stray Park to Dolcoath for sending the men up and down.

8674. What would be the extreme distance from the farthest level at Stray Park to the man-engine at Dolcoath?—250 fathoms.

8675. Would the men rather walk that distance than go up the ladders?—Yes; some of our men in Dolcoath walk as far as that.

8676. But would they all prefer that to climbing up by the ladders?—Very much.

8677. How long does it take to come up from the lowest level at Dolcoath?—Half-an-hour in the man-engine, that is the limit of the time; sometimes they draw them up in 25 minutes; but I have given an order that they should never drive the engine so fast as to get the men up from the 220 fathoms in less than half-an-hour.

8678. How many men do you suppose go down into the mine at one change of cores?—We can take in 110 men to go down, and 110 men to come up; that can be done in one hour; there are not so many always at hand; that is the largest number we can take. 50 or 60 an hour can be taken down and brought up very easy; that is done often.

8679. Do you use a skip or a kibble in the mines?—At West Seton and Stray Park a skip is used; at all the other mines a kibble.

8680. Do the men ever try to come up in the skip at West Seton?—We never allow it to be done, and they do not aim at it, for the ladders there are so easy to get up.

8681. Is there any reason for using a kibble and not a skip in the other mines?—It is principally because of the time that would be required to remove things in a mine 300 fathoms in depth, and to change the mode of drawing would be attended with considerable interruption to our workings, for a mine of that depth. I know the prevailing opinion of the mine agents generally throughout the country; but I think we can show now from our books that we draw in Dolcoath mine, with common kibbles, birch plank, and taper chains, beginning with three quarters of an inch, and coming down to half an inch, as cheap, if not cheaper than in any mine in the county at the same depth.

8682. Would it affect the returns to the adventurers and therefore affect the value of the shares?—Yes.

8683. If you found it advantageous to substitute a skip for kibble, how would that at all put out or derange the work in the mine?—I do not think we could do it in one of our shafts in Dolcoath at all, in less than six months, to make it large enough to take two skips; and to attempt to draw with one would be fatal nearly. The cost would be so great in drawing with a single skip, without any balance against it in going down; it would be much more costly than drawing with kibbles.

8684. You are of opinion that in order to use skips with advantage, it would be necessary to have a double apparatus?—Yes, for all deep mines.

8685. Therefore the shaft would have to be enlarged for that purpose?—Yes, it would be so with us with our old shafts that were sunk a long time ago.

8686. Therefore, although it might be an advantage ultimately to the mine, yet, as it would stop the returns from the mine for six months, the value of the shares would be depreciated?—Yes; and the adventurers could not have their usual dividends. For myself, I do not hesitate to say that if the adventurers were to say to me in the Dolcoath mine "Throw out the kibbles and put in skips if you like," I should say, "No; I will keep on the kibbles still." We have our shafts now in such excellent order, with birch plank, that the kibble will run over it like over a bottle, with scarcely any friction at all; and the kibbles never touch one another. That was one object in having the skips, that they should not come in con-

tact one with another, and our kibbles do not come in contact one with another. We draw now in Dolcoath mine 12 cwt. in a kibble, and that is the weight which they draw in other mines with a skip. We have a chain such as I have described before.

8687. Suppose you had a shaft of sufficient dimensions to enable you at once, without any expense as to the shaft, to use a double skip, would you then adopt it?—For a deep mine I would not. I would have a kibble for a deep mine.

8688. If you were sinking a new shaft in a deep mine, would you sink it so that you could apply a skip to it?—That would depend upon the underlie of it; with a quick underlie I would certainly. At West Wheal Seton, we had a skip road put in there under my directions, and that I would do again where the shaft is going out, with an underlie of three feet or three feet and a half in a fathom; but with an underlie of only two feet in a fathom, or a perpendicular shaft, my mind would hang nearly in the balance, and I would as soon have a kibble as a skip with a perpendicular shaft, or with a shaft with an underlie of not more than two feet in a fathom.

8689. With an underlying shaft you would prefer a skip to a kibble?—Yes.

8690. Do you keep any account of the cost of keeping the shaft in repair where you use the kibbles?—Yes; it is all put down; it is booked every day that a man is engaged in the shaft, separate from every other cost, and then at the end of the year I had frequently taken out all the cost of the chain and the kibbles, the oil and the enginemen's labour for the year, and then we had, in Dolcoath especially, the means of ascertaining the quantity drawn to the surface quite as full and distinctly as in any other mine in the county, because we have all the tin stoped by the ton, and we pay nearly all the tut workmen in driving ends and sinking winzes, partly by the ton. Then, from that we can ascertain very nearly the actual quantity drawn, and the last account that was made out for the year 1861 showed that the whole of the cost, except filling and landing, which must be done under all circumstances was 1*s.* 2*d.* a ton for drawing from an average depth of 280 fathoms; that included the consumption of coal, oil, enginemen's labour, chain, kibbles, and repairs of shafts. I doubt whether there is any stuff drawn in the county so cheap under any circumstances.

8691. In Stray Park I think you said you use a skip?—Yes.

8692. Do you keep a similar account there?—No, not so correctly. I cannot speak to the cost there. I have taken the cost in West Wheal Seton as nearly as it could be got, and I find there for the depth that it costs rather more to draw by a skip than it does in Dolcoath by the kibble.

8693. Which of those mines should you say was the hottest?—Dolcoath is the hottest.

8694. Do you employ any artificial means otherwise than by winzes and shafts to ventilate Dolcoath?—At present we do not; we have occasionally done so. We had six months ago a fall of water of 10 fathoms deep, which was forced in through air pipes for a short period until there was a communication made. Now we have no artificial means.

8695. Do you think that the winzes and cross cuts and shafts are sufficient to ensure sufficient ventilation?—Fair ventilation of that kind, so that there is no difficulty in burning a candle at all; every candle in every part of the mine will burn perfectly upright without any difficulty. If we found it required that the candle should be turned aside to burn freely, we should at once devise some artificial means to convey air for the men to work in.

8696. The candle is the only means that you have of judging of the state of the air?—Yes.

8697. Do the men never complain of the state of the air before the candle will not burn freely?—I never heard of it in a single instance that I remember.

8698. In any of the other mines have you had to employ artificial means to supply air?—Yes; in West Wheal Seton now means of that kind are occasionally used We have had a fan to force in air, and a kind of plunger to force air in with. When we have a long way to drive it; it is occasionally worked by the steam-engine; it is a simple apparatus—a box swimming with water, where there is no friction at all, and that is a very efficient mode of sending in the air; it is a box turned upside down in another, or a cistern turned upside down.

8699. (*Mr. Holland.*) Are you speaking of a duck-engine?—Yes.

8700. (*Chairman.*) At this moment have you any of these cisterns at work at West Seton, or at any other mine?—At West Seton now we have nothing but a fall of water for two rather long levels, and that is most efficient when we can have it; there is nothing equal to that.

8701. That is in two levels that are at work now?—Yes.

8702. Which are those levels?—The 82 and the 90.

8703. Can you inform the Commission what quantity of water is sent down or what quantity of air is supplied?—Perhaps 20 gallons a minute; I think so.

8704. Have you ever tested the quantity of air that is supplied?—Only by putting a candle to it. I do not know the quantity.

8705. When they have felt an end to be close you have introduced a waterfall, and then they found the closeness to be completely remedied?—Yes.

8706. Have you ever tried a soller in any of your mines?—Yes; formerly we did that more than we do now. We do not drive in any mines that I am connected with very long levels without making a communication. We never do that now.

8707. What is the furthest distance from any winze or shaft to which you now drive?—Seldom more than 30 fathoms, or from that to 40 fathoms.

8708. In your opinion is a soller a sufficient mode of ventilating a level?—It is very useful when you have a strong draught coming through the level, putting in a soller there, and then throwing all the air under the soller.

8709. May not a soller be in a level without supplying sufficient air to the end?—Yes; it depends upon the quantity of air that you have passing through the level. You can, of course, only take up the quantity that is coming through the level; if there is but a slight draught coming along it would not be very efficient to force it into a long level; sometimes we have a very strong current, and then to take hold of that, the air then that will go in under the soller is very effective.

8710. Would you recommend that the soller should be on the bottom or at the top of the level?—Generally they are in the bottom. Sometimes I have seen them on the top, but if it is to force in a strong draught, I would have it under rather than over. When it is getting into a warm end then the air will be very much rarefied, and then it will pass over the soller going back again.

8711. It is possible that a captain, when a soller has been put in, may believe that the end is sufficiently ventilated when it is really not so?—It could not convey any more than is passing; there is always a check upon that; you never can convey the full quantity of air passing through a level; and before we think of putting up an air-door, we may by the candle or by our own sensations ascertain the strength of the air coming along, and if there is not much we never think of putting in a door.

8712. Have you tried the current of air by the anemometer?—No.

8713. Do you think the fan is an efficient mode of ventilating a level?—It will do for short distances. I should prefer a plunger or one of those simple little machines that I have described for forcing the air through a very long level.

8714. You think that the machine you have described for supplying air is preferable to the fan

CAMBORNE.

Capt. C. Thomas.

5 August 1862.

machine?—Yes, for long levels especially; it requires less labour to work it, I think.

8715. And it can be worked by any machinery you like to attach to it?—Yes.

8716. (*Mr. Holland.*) Is it cheaper for the same quantity of air?—I think it is.

8717. Is it cheaper to make?—It would cost about as much as a fan would.

8718. For the same quantity of air?—Yes, I suppose so; but this one to which I have referred has been in use for the last 30 or 40 years in different parts of the county. I prefer it to any other mechanical contrivance next to a fall of water.

8719. Is that the machine called Taylor's duck-engine?—No.

8720. (*Chairman.*) In any of these mines with which you are connected, what is the longest time that the smoke takes to clear away from a close end after blasting?—It is a considerable time before the whole of it would be driven off or moved off; but, generally speaking, with very few exceptions, in the mines I am connected with, the smoke would move off, or would be so far passed away as to enable the men to work with a little inconvenience, perhaps, in ten minutes; sometimes they may have to wait for a quarter of an hour before they could go to work again comfortably, not longer than five minutes in some places, and in some other places not more than two minutes; we do not let the men go into an end, if we can avoid it, until the smoke is partly passed away, but they will rush in, and we always think there is some risk connected with their going in soon after the blasting of the gunpowder.

8721. Have you in any of these mines any end in which the air is poor?—Not now in any one of the ends in any one of the mines of which I have the management; there is not one end but where the candle will burn perpendicularly and freely.

8722. I suppose if it is reported to you that the candle will not burn, you take means to remedy the bad state of the air?—Yes; whenever we find that by going there ourselves, if the men do not complain, we always order something to be applied.

8723. Have you any men who are specially employed to look after all the machinery in a mine, the ladders and so forth?—Yes, we have one who is specially employed to take care of the man-engine; he is paid 1*l.* a month for that in addition to his other duties.

8724. Is it his duty to see that all the ladder-ways and all the openings over the winzes leading from the levels are properly covered up?—The timbermen have always that to do as part of their work.

8725. Is there a bargain made with those timbermen?—No, they are all paid alike.

8726. Is it not the business of anyone in particular to report upon those matters specially?—It is the business of the timber-men to go at once and repair anything that is faulty without asking for liberty; that is part of their duty. When they find a stave gone out of a ladder or a board gone out of a platform it is their duty at once to go and mend it without naming it all.

8727. Is there no one to report to you that all that is properly done?—No; we see it ourselves, as we go through the mine. It ought to be, perhaps, in connection with this matter, stated that the captains go through every part of the mine, and if they see anything out of order they would call upon the man in charge, and order him at once to put in a stave, or put in a board that was wanting.

8728. How many sub-agents or captains underground have you at Dolcoath?—There are two who are called underground agents; my son is assistant to me as manager.

8729. At Cook's Kitchen how many sub-agents or captains are there underground?—There are two underground captains. I am the manager alone there.

8730. How many underground captains are there at the other mines?—At West Seton there are two underground captains; I am the manager. At Stray Park there are two, at West Frances there is one, and at Calvadnack there are two. My son assists in the management of the three last-named mines.

8731. With the agency that you have employed in these mines how frequently are the underground workings inspected?—Some of the scattered pitches perhaps only once a week; all the principal parts of the mine are inspected twice a week, but a couple of men may take a pitch in some distant part of the mine, and if that is seen once a fortnight that is as much as we think necessary.

8732. How often are the tutwork bargains looked to?—Three times a week we consider sufficient for our hard-ground mines. In soft ground we should see them oftener, but in hard ground the change that would be effected by a pair of men working for two days is just nothing.

8733. Do your underground captains go underground at night?—Very seldom indeed; not in deep mines, excepting in cases of an extraordinary nature.

8734. So that you trust to the men who are at work—the tutwork men, the tributors, and the timber men—to comply with the rules laid down for their observance?—Yes.

8735. Is all the work let on contract?—Yes, all in Dolcoath mine for one month, or for two months. I should say that we never set a single bargain in the course of a month we set out all the stopes in the mine at so much per ton for what is fit to stamp when it is brought to the surface; they are a kind of tributors, and they depend quite upon their own resources; if they break down deads instead of tin they get nothing for it; they are confined to breaking tin stuff, that will pay for stamping when it is brought to the surface.

8736. I suppose you drive your levels six or seven feet high?—They are eight feet by six; all at Dolcoath.

8737. Do they take care that there is no accumulation of refuse or deads allowed to remain in the levels?—Yes; in all the working levels we take care of that; after they are gone out of working for a time there may be accumulation.

8738. Are the tributors and the tutwork men bound to see that those levels are cleared out, or how is that done?—They are under an obligation to do so; sometimes we are obliged to say to a pair of tributors, "Here is this stuff lying about here, and you must remove it before we come again."

8739. They are bound to do so themselves, are they?—Yes, they are bound to do so by their contract.

8740. Have any accidents occurred within the last three years at Dolcoath?—Yes.

8741. Of what description have they been; accidents by blasting?—I do not remember for the last two years an accident by blasting in Dolcoath of any serious character. In Cook's Kitchen we have had no accident the past four years by blasting.

8742. Will you be kind enough to furnish the Commission with a report of the accidents that have occurred in the last three years in those mines?—Yes.

8743. Have any accidents occurred from the men falling away from the ladders?—That is a very rare occurrence. I do not remember one for a long time in any of the mines.

8744. Do you take any special precautions against accidents arising from blasting by employing any particular kind of tamping rod or cartridge?—We do not use cartridges much; never, excepting when we have wet ground and water to deal with.

8745. Is the tamping rod that you allow to be used of a particular kind?—We use a safety fuze and an iron rod.

8746. You do not use any wooden rod?—Yes, to pack in the powder, always.

8747. Is each man supplied with an oaken rod to put in the powder with?—He may have it by going to the carpenter's shop for it; they do not have them prepared for them, but every man may have it, and

every man has what is called a swabbing stick; the lower end of that is roughed up a little to clean out the hole before they put in the powder; the upper end ought always to be kept in condition to pack down the powder with.

8748. Is any penalty imposed upon the miners for not using it?—No; but we charge them, because at Calvadnack mine, six months ago only, some of the men persisted in packing in the powder with an iron bar instead of using a wooden rod; they were warned of it, but they still persisted in it, until at last two of them were very seriously wounded in the very act of packing in the powder; before they had tamped it at all the powder exploded and burned them very severely.

8749. Is it not desirable to use a tamping rod which would not produce sparks by striking against the rock?—I do not remember a single instance in which the premature blasting of a hole since we have had the safety fuze has been occasioned by striking fire against the side of the hole.

8750. How have the accidents occurred?—Either by putting in the powder first of all with an iron rod, or the first or second tamping perhaps, when they have not packed down the powder sufficiently with the wooden rod; when they first come to put in the first tamping, and that first tamping is forced in upon the powder it may explode sometimes by undue pressure, that is what we have thought sometimes.

8751. Your impression is, that explosions sometimes take place by the mere compression of the air?—Yes, that might have been lodged in with the powder before; that opinion prevails rather extensively amongst miners.

8752. Is that your own opinion?—I am inclined to it, although I have not a decided opinion about it. It would be equally dangerous whatever might be the material of the tamping rod. Then there is another thing, the cutting of the fuze, which occasionally takes place; the kind of tamping that is used is a matter of great importance for safety. If very hard tamping is used then that hard tamping may cut the fuze, and then of course the powder in the fuze would be reached, and then an explosion might take place.

8753. What would ignite the fuze in that case?—If there was hard tamping, hard fiery stone, that in being driven with an iron bar, if at the same time it would cut the fuze, would scratch the side of the hole too; it might be done in that way.

8754. But would the hard tamping coming against the side of a hole create a spark?—If the hole is very hard, and the tamping was of a similar character, it might possibly do so.

8755. Even although it were driven in with a wooden rod?—It would not then depend upon the nature of the rod at all, if that were so.

8756. Do you give out any particular kind of candles for the use of the men in the mine?—We have two sorts. Some come from London, Palmer's candles, which are stiffer for working in a warm atmosphere—they stand stiffer, and they do not run as the common tallow candles do.

8757. Palmer's candles are better in a warm place?—Yes.

8758. What is the difference between the wholesale price of the common candles and Palmer's candles?—Just nothing; one price.

8759. Do the men pay the same price for both?—Yes; they are at liberty to choose which they will have; we keep both sorts in the mines, and they may take either Palmer's or the others. All the men working in open places will take the others, but a few of the men who are working in rather warm places prefer occasionally to take some of Palmer's.

8760. Does the heat of the weather affect Palmer's candles so that they stick together?—We find them so occasionally, but we think that there has been an imperfection in the manufacture then; we rather think that they may have been put together before they were properly cooled.

8760*a*. Is the light given by both the same?—Yes, the same; there is very little difference.

8761. What price do the ordinary mines pay per pound for candles?—8*d*. per pound now generally.

8762. Are they limited to a certain allowance of candles?—In some mines they are; but unless we find in any of them that they are taken out in an extravagant quantity we do not limit them. We think that the price ought to be sufficient for all reasonable men. We only pay 5*s*. 6*d*. a dozen, and they pay 8*d*. a pound, so that they pay 2½*d*. a pound more than we pay, and that we consider ought to be an effectual check to taking out more than they really require. There are a few men who will break through propriety in that respect, and then we mark them down and say, "You shall only have a certain number of pounds."

8763. Do you mean that even at that high price they would sell them?—Yes, they would sell them, perhaps, to buy tobacco—some reckless men.

8764. The high price is not a complete check?—No; but it is a very effective thing for all the thinking steady men; for one in ten it is not a complete check.

8765. I suppose that the well-conducted thinking men would not dispose of the candles even if they obtained them at a smaller price?—No.

8766. It is only in the case of the ill-conducted men that this check is necessary?—Yes.

8767. Is it always effectual in their case?—Not always.

8768. The Commissioners have heard of a mine having been lighted with gas; in your opinion would it answer and be economical to use gas in a mine?—I do not think it would. I saw that mine that was so lighted—Balleswidden.

8769. Can you furnish the Commissioners with an account of the quantity of candles consumed or supplied to the men in one year in any one of your mines?—In Dolcoath mine the consumption is about 3,300 dozen a year, or rather more; I would say 3,600 dozen.

8770. And what in the other mines is the consumption?—In proportion to the number of men, about 2 lbs. for each man per week.

8771. Do you use any special kind of powder in your mines?—We use the Kennal Vale powder, and occasionally the Dartmoor powder, and some which comes from near Liskeard in some of the mines.

8772. Is there any difference in the powder that is used?—There is not much in all the powder mills I have named, but there is another kind of powder that has been brought into use recently by Mr. Davey; there is some difference in the composition, but I do not know what it is exactly.

8773. It does not produce so much smoke as the other, does it?—No.

8774. That is an advantage?—Yes.

8775. What does that powder cost?—50*s*. per cwt., 6*d*. per pound, the same price as the others.

8776. What do you charge for the powder?—8*d*. a pound generally.

8777. What do the men pay for club money?—In some mines they pay 6*d*. and in others 9*d*. a month.

8778. In Dolcoath how much do they pay?—9*d*. now; it was 6*d*. for seven years, until about a year ago, 6*d*. was not found quite sufficient to pay all the demands upon the club, and then we charged the men with 9*d*. for a time; and as soon as we have got a little accumulation, so as to be able to carry on the working of the club, we shall fall back to 6*d*. again.

8779. Did the deficiency arise in consequence of the occurrence of accidents?—Partly from that, and some widows who had been on the club for some time, some of them for 10 years.

8780. Is the club money used only for visible accidents?—They have no legal claim according to rule, except there is a visible wound.

8781. In the case of the widows to whom you have just referred, did they become widows in consequence of their husbands losing their lives by accidents?—Some of them only. Others had died after a very long

CAMBORNE.

Capt. C. Thomas.

5 August 1862.

service in the mine, worn out, they had been working in the mine for perhaps 20 or 30 years, and in those cases the widow receives some allowance for a year or two; we have had one for seven or eight years receiving three shillings a month.

8782. Is there a correct account kept of every club fund?—Yes, always.

8783. Do you consider the club money to belong to the adventurers or to the men?—There is a difference of opinion about that. I believe that the adventurers generally claim it as their own if a mine is shut up.

8784. Do you know of any case in which, where a mine has been shut up, the club money bas been applied as part of the assets of the mine?—There was a little mine, and at the close of it there was about 30*l.* in hand. I had the management of it; there were two or three persons on the club, and we made a present to them of something considerable; I do not remember what, but we thought it just sufficient to meet their case if they had continued to work in the mine. After that there was still a balance left of, perhaps, 25*l.*, and I said to the adventurers, "I do not consider "that you have a positive claim upon this, and the "way in which I intend to appropriate it is this:—I "will not charge any wages for myself, nor for the "agents on the mine, for closing up and selling the "materials, and winding up all the accounts, and un- "less you say that I shall not do it, I shall take this "money and pay myself, and pay my agents out of "club money instead of handing it over to you. I do "not consider that you have a positive right to it." That is now 10 years ago, and since that time the sentiment has turned round in favour of the adventurers, and they say that it is their money now; but that did not exist then, and if I were in the same circumstances now it is not likely that they would let me take that course.

8785. Has any case occurred lately that has been referred to arbitration in which there was a considerable amount of club money?—There was something about the Camborne Vean mine. I do not recollect the circumstances, but I think that that was referred to arbitration.

8786. Is it understood that this money belongs to the adventurers, and that they can apply it for the purpose of affording relief to widows, departing from any strict rule as to its being applicable only to accidents?—They let us do so in the mines that I am connected with; they do not interfere about it; they never interfere. They do not ask what you do with the club money in any mine that I am connected with. We always show the account; that is thrown as much open to the auditors as any of the accounts in the mine. We show an account of every penny received, and every penny paid, where it is gone to. Every name is down in every mine that I am connected with.

8787. In the Dolcoath mine, where you had to raise the contribution of the men from 6*d.* to 9*d.*, had the men no account shown to them to explain why you were obliged to do so?—No.

8788. Do you charge the men so much for the barber?—Yes; 3*d.* a man, and I would strike that off if I could. I tried to do it seven years ago, but I did not succeed.

8789. How much do the men contribute to the doctor?—6*d.*

8790. How are the doctors appointed?—They are appointed by the adventurers always. The men have no voice in that.

8791. Is it your opinion that it would be advantageous if the men had a voice in that matter?—No, I do not think so. There would be such a variety of opinions if the matter were put to the majority. The doctors would be running about to the men, and asking them to vote for them and so on.

8792. They do that with regard to the adventurers; they canvass them, do they not?—Yes; but they are not likely to influence the adventurers so much as some of the men.

8793. Do not the medical men take shares in a mine in order to get elected doctor?—Yes, very often.

8794. Are they ever nominated by the lord now?—I have not heard of any instance of that kind in any mine that I am connected with.

8795. Have you any rules as to the time when the boilers should be cleaned out?—It is left with the engineers generally. If they say that a boiler ought to be cleaned out, it is always attended to. There is an engineer in charge of all the machinery in every mine.

8796. How does he ascertain when it becomes necessary to clean out the boilers?—The flues are outside the boilers, where all the fire is passing along, and it can be ascertained from the draught. If it is choked, then it is time to clean it out; but in the mines here there is but very little sediment in the boilers.

8797. Have they any means of testing a boiler, whether it is quite safe, or whether the plates have become weaker from any corrosion having taken place?—No; unless by stopping it.

8798. Have you heard of boiler explosions in the county?—Yes; and those we believe to have occurred universally, or with scarcely an exception, on account of the boilers not being kept full enough of water. When the tube has been covered with water we have never heard of an explosion.

8799. How can it be ascertained that it is so?—They have cocks at the level of the tube.

8800. Is it to be ascertained only by that means?—There is no other test than that here. We formerly had a buoy with an iron spill working through a collar, so as to show the depth of water in the boiler.

8801. Have you ever seen a glass tube used for testing the boilers?—We have not got them in any of our mines.

8802. Then everything seems to depend upon the man who is in charge of the boilers, and whether he tests properly the quantity of water in them?—Yes, that is all.

8803. Are the men who have charge of the boilers experienced engineers, or are they sometimes men whom you have been obliged to put to work at grass?—They have scarcely any of them been trained to become engineers. They are men who have been employed in other departments of the mine who have been chosen—men in perfect health and strength, to go to work at the engines. Sometimes their health will fail a little. We have some cases of that kind in Dolcoath mine in working small engines. They are not very strong, but they are perfectly able to work those small machines.

8804. Are there two safety valves to your boilers?—There is one generally speaking to each boiler.

8805. Do you not as manager receive any report as to the time when the boilers are cleaned out?—No; there is no regular order.

8806. In paying the miners what proportion do you pay to them in notes, and what in gold?—In Dolcoath mine, which may be taken as a guide for all the other mines, the money paid away is about 3,000*l.* a month for labour, and we pay 1,000*l.* in notes and the other 2,000*l.* in gold and silver; about 200*l.* in silver, and the other 1,800*l.* in gold.

8807. Do you think that that affords a man an excuse for going to a public-house to get a note changed?—He may make it an excuse, but there is no necessity for it. There may be 5*l.* paid in a bill, and one might have to receive 15*s.*, another 18*s.*, another 17*s.*, and another 16*s.*, or one will have to take a sovereign and another half a sovereign perhaps.

8808. Then must he not go to a public-house, or to some shop to get it changed?—Yes, to a shop they go on taking up a month's meat before they have money to pay for it. They get into debt for a month, and then they go to a shop to pay for it; a large portion do this.

8809. They are always a month in arrear, are they not, in receiving their pay from the mine?—Yes, always in all the Cornish mines.

8810. For example, a miner who goes to work at first in a mine, having left another mine, receives no

pay for two months?—He has no claim to any; but at the end of the first month he always, without exception, asks for what is called subsist, and we always grant him perhaps one-third of a month's wages, but that has to be carried over the next three months before he clears it all up, for tribute or tut work either. If a man comes to work, at first he would have to wait, according to the rule, two months; but at the end of the first month universally he is treated as I have described in every mine that I am connected with, or that I have a sufficient knowledge of to give an opinion about.

8811. Do you usually give subsist to all the men?—Not to those miners who take on for one month; but if they take for two months then we give them subsist at the end of the first month, closing up the account at the end of the second month.

8812. What amount of subsist do you generally give them?—If a tutwork man takes a bargain for two months, at the end of the first month he would receive 3*l.* for subsist, as we hope that he will get 3*l.* or more; we give him half the money, or 3*l.* at the end of the first month, and at the end of the second month he has to close up his accounts and receive the balance, whether it be 2*l.* 3*l.* or 4*l.*

8813. How much do you give to the tributors?—2*l.*

8814. Is it the general rule throughout Cornwall to grant them that amount of subsist?—I think it is very generally given, the 2*l.*; very few tutwork men will take for two months; except in West Seton, and in Dolcoath and Cook's Kitchen I do not know any. We set the stopes, instead of by the fathom by the ton; at West Seton too, in copper ore, as well as in Dolcoath; we think that that is the simplest way.

8815. In other mines it is set to the tutwork men by the fathom?—Yes, and for one month only generally.

8816. Then they would not receive pay for two months; they would always be two months in arrear?—One month in arrear.

8817. I mean that they would have to wait for two months before they got anything?—Yes, except as a favour.

8818. In those cases, is it your belief that they give for subsist more than 1*l.* a month to the tutwork men?—I do not know; we give 2*l.* to the tributors, and 3*l.* to the tutwork men, but no subsist at all for a month except a man asks for it as a favour, and then we do.

8819. Suppose a man does not receive any pay for two months, he must necessarily begin by getting into debt?—Yes.

8820. What provision do you make for the women who are working on the surface, to enable them to get their dinners?—We have at the Dolcoath mine four establishments with a large oven in each of them, large enough to contain 200 pasties or hoggins. Then we have benches around a long room where they can sit down, and hot water is always prepared by the dinner time. As soon as the bell rings they rush in to get their dinners; and so many of them as like to do so join together, half a dozen perhaps purchase a tin kettle, and every one brings a cup, or as many as like to do so, and if they join together they get a little tea with the water.

8821. It is very desirable, is it not, that the women and children should work under cover, and have a separate place to take their meals in?—Yes; it is an advantage to the mine as well as to the people.

8822. And that the men should also have a place near the footway to change their clothes in?—Yes, it is a great advantage. At Cook's Kitchen it is exactly the same, and at West Seton. We have 800 persons working at the surface at Dolcoath Mine, and 300 at Cook's Kitchen, and 300 at West Seton; and one advantage is, after the dinner hour is closed, upon the ringing of the bell, the captain is there to see that every one is out to their work again in a minute, and but for such an establishment as that they would be scattered all over the mine in a great variety of places, and it would take a quarter of an hour to get them to their work again.

8823. (*Mr. Holland.*) You stated just now that you thought it better that the doctors should be appointed by the adventurers rather than by the miners?—Yes, I said that I preferred it.

8824. If there is more than one doctor appointed to a mine, the men have a choice, have they not?—Not always, sometimes they have. They would have a power in this case; suppose there were two doctors, if the men preferred having the one to the other, they would be at liberty to go to that one; but there is a private arrangement between the doctors themselves in Dolcoath, one would have one week and another another week; they say between themselves, "You attend to the men this week, and I will attend to them next week;" but if there is one man for one week and they prefer to have the attendance of the other, he would at once go.

8825. If the adventurers appointed two doctors would not the men in that case have an opportunity of making a choice?—Yes.

8826. You stated just now that you were anxious that the men should not go into the ends before the powder smoke was cleared away, do you think that that is injurious to them?—Yes, very injurious; when it is very hot after a place has been blasted, there may be some carbonic acid then let loose, and that would settle down in a few minutes in the bottom of the level from being heavier than the common air; that is our notion about it.

8827. You consider that it is very injurious to go into an end shortly after a shot has been fired?—Yes, I find that it brings on cough; if I have gone in I have found that it disturbs my regular breathing.

8828. You think that that is a well established fact?—Yes, very well established; Mr. Davey especially told me, "I wish you would give the men "warning not to go into any of the ends very soon "after blasting."

8829. Is the heat from the powder smoke after an explosion so great as, in your opinion, to injure the lungs?—It is never so hot as that, I think.

8830. I believe it is your opinion that the miners as a body are more healthy than they were 20 years ago?—Yes.

8831. Why do you believe so?—I do not see so many of them going about in consumption as I used to do; we do not find them on our club books; they decline, but not with consumption.

8832. What becomes of the old men?—A great many of them are now engaged in this parish as small shopkeepers and small farmers. I do not know exactly the number, but I think there are 70 or 80 in this parish who are so engaged. When they reach the age of 40, if they have accumulated a little capital, a few score pounds, they will sometimes go and keep a little grocer's shop, and then perhaps advance to something a little higher; there are here now, I think, 30 owners of houses who were once miners.

8833. If they died now they would be registered as shopkeepers, would they not?—Yes.

8834. You are sure that that is the fact?—Yes, I am sure as to a great number; I cannot speak to the exact number.

8835. I find that out of 481 men, tributors, tutworkmen, and pitmen, there are only 40 above 45 years of age now at work?—I do not remember the exact number; but we have a larger number of young people in Dolcoath mine now than in any other mine that I am acquainted with. The number has doubled during the last ten years. We have taken them from our dressing floors, and brought them up for miners; for three or four years we could not get men to work in all the places, and we got them in as boys to work with two men, and trained them in that way. We have a larger number of young men in Dolcoath mine on that account than in any other that I am acquainted with; the old men, or those who were comparatively old, emigrated; as they had not moved away from the other mines to come to our mines, they had remained where they were, but these young men are very steady and there have been a great number brought

CAMBORNE.

Capt. C. Thomas.

5 August 1862.

in from the dressing floors, lads of 15 or 16 years of age, and they fill up the mine.

8836. At what age do the men emigrate, chiefly?—From the age of 25 to 35, I should think, more especially.

8837. Are there not many more at the age of 25 than at the age of 35, or more before 35 than afterwards?—Some young men go away.

8838. Is it not much more easy for a man to emigrate who has a small family than for one who has a large family?—Yes, I think it is. Men with large families do not generally like to leave, but a man with a wife and one child goes away very often, and that would be from the age of 25, but, generally speaking, it is from the age of 35 to 45; men of energy and mind and physical power, they will move off to wherever they think they can do better.

8839. If the healthier men go away the less healthy stay behind?—Then the result would be shown at once; then we should have a larger number of deaths than we should have had if they had all remained at home; a greater number would die yearly, and on the whole the average length of life would then be less than if those strong ones had remained at home.

8840. Do not you consider that the fact of so small a proportion as eight and a half per cent. being at work above the age of 40 is an indication that the occupation is very unhealthy?—It is not so healthy as farm labour, but it is as healthy as labour in the manufacturing districts is, generally, as far as I know; it is unhealthy to a certain extent, and tends to shorten life.

8841. Why do you think it tends to shorten life?—I attribute it partly to the air being not so pure as it is at the surface; it cannot be so in all departments of the mine. I do not know of any mines that get it so. I should rather be inclined to think that the climbing of the ladders by the young men so very quickly as they do may tend to bring on chest complaints; sometimes they will run to the ladders, and endeavour to outvie one another, and very often we check them as much as we can, but I was like that myself when I was a boy.

8842. Is not the great heat of the mines very injurious to those who work in them?—I can show you what the temperature is in Dolcoath and in West Seton.

8843. Do not the men come up from below very hot?—They do not come up from below very hot now, ascending as they do by the man-engine; when they come to the surface they are not hot at all, when they come up to the surface they can breathe freely, without being heated at all. This is a section of the principal workings in Dolcoath mines (*handing in and explaining the same*).

8844. Is that (*pointing to the section*) an upcast or a downcast shaft?—The air generally comes down the eastern part of the mine, and goes up in all the western shafts.

8845. How is it in the engine shaft, is it up or down?—I do not think there is any regular order, it is generally up here (*pointing to the section*).

8846. Do you not think that it would be a great protection against catching cold if the men could bathe themselves, instead of simply washing when they come up; for example, suppose there was a tank in which they could bathe?—I do not know I am sure whether they would like it when there was 100 of them together; perhaps they would not like to strip naked, they take off their shirts; they bathe in warm water down as far as this (*pointing to the middle of the body*), which Dr. Peacock said was an excellent practice in warm weather, and they rub themselves with towels. The men do not come up very hot as I have stated before.

8847. (*Mr. St. Aubyn.*) You stated just now that you think the miners, as a class, live longer than they did in former times?—Yes.

8848. To what do you ascribe their improved health and longevity?—Better ventilation generally, and from better provision being made for the men to change their clothes before going underground, and after they come up. There are warm places provided for them in which they can dry their clothes.

8849. In the different mines of which you have the management have you observed that the men enjoy better health in some mines than in others?—I do not know of any marked difference in the mines of which I have the management.

8850. Is a man-engine employed in any of the mines that you manage?—Yes, in two of the mines.

8851. Have you observed no difference on that account in the health of the men?—In the deepest mines; but the others are comparatively shallow.

8852. Therefore the benefit would be neutralized?—Yes.

8853. You have stated that the cause of the miners living longer is that the ventilation is better; is it, in your opinion, as good now as it could possibly be made?—I do not say that; it can be improved no doubt.

8854. What, in a few words, should you say was the best means of improving the ventilation, so as to make it as good as it could possibly be under present circumstances?—Where they have got a sufficient number of shafts, the best thing I think is a fall of water, when you can have it, and the next best thing is that instrument which I have partially described for forcing air in.

8855. To which there is a cistern?—Yes, but it must be always fixed in good air; great care must be taken about that, or else bad air will be blown into the men after all.

8856. In fact it must be properly managed?—Yes.

8857. Are you of opinion where it can be introduced and properly managed that a man-engine would always be one means of improving the health of the miners?—No doubt of it. When a mine gets deeper than 100 fathoms I should recommend, where it was at all possible or convenient, the setting up of a man-engine; there are some mines, where the inconvenience would be very great, for they would have to sink a new shaft. I should not advise the adventurers under such circumstances to go to the expense; it would depend upon the stability of the mine, as far as that could be judged of, and a great number of circumstances must be taken into account. To lay down a universal rule that in every mine there should be a man-engine at a certain depth would be an injury to the well being of Cornish mining.

8858. You would say shortly that where it was possible to improve the ventilation in the way you have suggested, and where it was proper and convenient to introduce a man-engine, if those two things were done, as much as possible would have been done to improve the health of the miners?—That is my judgment.

8859. You have stated that you do not think that gas would be an improvement in a mine?—The difficulty of using it is very great. I saw the working of it at the Balleswidden mine; and in order to see whether it could be introduced into our mines here, some company from London applied to me for an opinion, and I had a long conversation with them upon the subject; but after I had seen it working at Balleswidden, I thought that the difficulties altogether would surmount the advantages to be derived from it; you want a constant light with you, and when a light is stuck up in one particular spot, perhaps a man would want to have it removed six feet away, and in a very short time he could not do that, whereas he can pitch up his candle from one place to another in a moment; and then when they blast their holes I found that they have to remove the pipes before they could be prepared to blast their holes at all; with a candle the men can run out in a moment. I consider that the convenience of a candle far outbalances the use or advantage of gas underground.

8860. Are you aware that it has been stated in evidence by the captain from the Balleswidden mine that he superintended that mine during six months

CAMBORNE.

Capt. C. Thomas.

5 August 1862.

while the gas was in operation, and the result of his experience is that if it were properly managed it would give a better light, would be more economical, and improve the health of the miners?—I do not know what his opinion is, I can only form an opinion from one day's visit.

8861. Have you never had a mine under your charge in which gas was used?—No.

8862. (*Mr. Kendall.*) Is the return which I have before me an accurate return of all the men and boys employed underground in the Dolcoath mine?—Yes, if that is the list I have sent in.

8863. Notwithstanding that this is an accurate return, is it not the fact that you cannot draw a correct inference with regard to the shortness of the miner's life as compared with that of the agriculturist, for these two reasons; first, that miners when they have made a little money very frequently become shopkeepers or small farmers?—Yes.

8864. And next that the miners emigrate a good deal?—Yes.

8865. So that it is impossible from these tables to compare fairly the average length of their lives with that of the agriculturists?—That is my opinion decidedly, after having examined the matter very carefully.

8866. Referring to all the mines of which you have the management, I understand from you that generally speaking the ventilation is good in them?—Yes.

8867. And where it is not good, by various contrivances, such as waterfalls, and the particular machine to which you have referred, and occasionally the fan machine, you are able, before you can have natural ventilation, to throw in a fair supply of air to the working miners?—We have the means of doing it, but it is not carried out so perfectly on all occasions as it ought to be; I acknowledge that fully; we have not perfected the means that we have now within our reach.

8868. As I understand your evidence, although much greater care is now taken of the miners, still a love of economy does sometimes so far prevail that in order to save a little money you do not set the fan machine to work so soon as you otherwise might?—It is partly that; the men say "We can work here very well;" and when we find that the candle burns very well we do not act so soon as we ought to do.

8869. If you were generally more attentive you think that you could with the appliances at your command send in quite air enough to the men, and make the mine healthy for the men to work in?—Yes.

8870. (*Mr. Davey.*) In the Dolcoath mine at what price is the ground in your ends worked out?—In the lower levels it is 25*l.* per fathom on the average.

8871. How many men have you at work in the deep ends?—Six or nine form a pare or company always we never allow one man to work alone.

8872. Supposing that the ground at Dolcoath was as easy to work as it is in the Gwennap mines, two captains would not be able to superintend the work of the mine?—No, unless they set as we do, and I think it would not be prudent to set as we do in very changeable ground; but our ground changes but very little indeed. We set out for one month or two months without any stint; the whole is set out for an end to drive or a winze to sink for a month, and in stoping as much as they can do in two months; they must drive the ends eight feet high.

8873. But a captain in easier ground would be required to visit the workings much oftener?—Yes.

8874. Have you ever known an instance in which the adventurers have paid money on account of the club when all the funds of the club had been used up?—I have heard of that, but it has not come under my own immediate observation.

8875. When your club got into debt you increased the contributions of the men?—Yes; we advanced the money from the general funds of the Company for that time; but we raised the pay from the men from 6*d.* to 9*d.*

8876. You say that you set the tin that is raised by the ton; is it by the ton of stuff or the ton of tin?—The ton of stuff.

8877. How do you ascertain the value of it?—We always, before putting it to the stamps, take samples of it.

8878. Do you ascertain the quantity of tin in a ton of stuff before you pay for it?—Yes; we simply try it in the usual way, and if it does not make one and a quarter produce, or one cwt. and a quarter of tin to 100 sacks, they have nothing for it. But then they must be on their guard that they do not blast down this poor stuff, for, if they do, they have no claim for any pay; it is a kind of tribute work—a mixture of tribute and tutwork.

8879. (*Mr. Holland.*) You have said that you thought the loss of life among the Cornish miners had been very much exaggerated, because a large number of the older miners had left their employment?—Yes.

8880. I find from tables before me that rather more than ten times as many Cornish miners die of consumption between 55 and 65 than other men of the same age?—But are they really cases of consumption?

8881. Of the disease registered as consumption, it appears that ten times as many Cornish miners die between the ages of 55 and 65 as of other men who die from the disease called consumption between the same ages. If that is true, does it not contradict your supposition?—I have no means of knowing.

8882. (*Mr. Kendall.*) How old are you?—68.

8883. Did you ever work as a miner?—Yes, for nine years. I went underground when I was 13 years old, and worked until I was 21 or 22. Then I became agent, and I have been agent ever since.

8884. Taking the average, how many fathoms do you go up and down in a week?—Not now so many as I used to do. I used to go underground four days a week to a depth of 200 fathoms upon the average, I think, for thirty years.

8885. Do you ever go under ground now?—Yes, twice a week upon the average.

8886. Do you enjoy good health?—As good as any man in England, I believe, for my age. I do not believe that there is a stronger man in England for my age.

The witness then withdrew.

Captain THOMAS RICHARDS examined.

Capt. T. Richards.

8887. (*Chairman.*) Of what mine or mines have you charge?—I have charge of various mines—Prosper United is the largest mine, Treloweth, Wheal Kitty, Trencrom, and several others.

8888. Are the mines of which you have charge principally copper or tin?—Some of them are purely tin, and some copper and tin.

8889. Will you be kind enough to state which is the deepest of those mines, and where the levels are deepest?—Wheal Kitty is the deepest, that is, 160 fathoms below the 30 fathom adit.

8890. Have you in any of those mines any other means for the men to go up and down than by ladders?—No; they are all ladders.

8891. Is it, in your opinion, better for the men to have ladders than to have some other means to enable them to go up and down the mines?—There is no question but what a man-engine is better for the men than climbing ladders.

8892. Would it be for the advantage of the adventurers or not to have a man-engine?—That is a matter that hinges a good deal upon the state of the mine. I think that if there is a sufficient prospect of any time, that is to say, if you could say they would go on for five or six or seven years, all deep mines would be benefited, and the adventurers too, by using a man engine.

8893. Although the time should be shorter, would

CAMBORNE.

Capt. T. Richards.

5 August 1862.

it or not be an advantage for the adventurers, on account of the greater amount of work the men could get through from ascending and descending by a man engine?—There are so many causes that are injurious; for instance, from climbing; men are so differently constituted that some men will climb well until they become old men, and yet some of those men are done up in a week; that climbing is very objectionable there is no question.

8894. Do you think that where a man-engine is used men of greater age can go down to work in a mine than where ladders are employed?—Yes; and then you have the advantage of their experience.

8895. Is it not an advantage to have experienced men employed in mines?—Quite so; it is a kind of work that time only makes a man suitable for.

8896. Therefore any means by which you could ensure the employment of experienced men in the mines would to a certain extent be an advantage in a pecuniary point of view to the adventurers?—There is no question that men of experience are better in any places, whether underground or upon the surface.

8897. (*Mr. Holland.*) Is not that peculiarly so in mining?—I think it is so all over the world; the best men are the most valuable.

8898. Is not the experience of a man of more value as a miner than in almost in any other employment?—If a man is a smith he will fashion a piece of iron with a hammer, whilst another with a swag will not make it better work; it is quite a matter of practice; some men excel in one thing and some in another, and for breaking ground there is no doubt that the best men are the cheapest in reality.

8899. Are there any hot or close ends in the mines of which you have charge?—They stand at about 78° or 79°, that is about the hottest.

8900. Is there any difference in the length of time that a man can work in an end according to the heat of it?—As regards a man being able to work in an end, that depends upon what sort of condition he is in, and how he lives. If a man is in good condition, by practice he would be able to work longer in those hot ends than other men could.

8901. Do you mean i he has plenty of food?—Not too much food. I think that the drink does more harm very often to the men for working than the food.

8902. You do not mean that there should be any deficiency of food?—No; I think that if our men had better wages generally—of course some men are provident and some are improvident—but it is surprising as to food; we find some very good men taking very little animal food. In the Lelant Hills, high country, especially there is a great deal of gruel and vegetable food, and not much animal food. In the western district, from St. Ives to the Land's End for instance, or St. Just, they are men who do not eat much animal food; they take more gruel and vegetables, and they are strong men.

8903. Do they eat much wheaten bread?—Yes.

8904. Is it wheaten flour?—Yes, if ever so little.

8905. (*Chairman.*) Do they get milk?—Yes, very often in those country places.

8906. Are the majority of your miners tutwork men or tributors?—I should say that they are about equal or about half and half.

8907. Does that vary according to the different mines, or is it the same over all of them?—It varies in proportion; in some mines we have very much more tribute than tutwork; it depends in part upon the size of the lode, and the nature of it as well.

8908. A miner works two months, does he not, before he is paid one month's wages?—Generally.

8909. Do you always allow them subsist?—A man coming into the mine would be two months, but there are many men who are several months in a mine, so that it does not make much difference; those who shift about we do not like.

8910. Do the miners shift about much in this district?—It is quite a matter of the mine; if you let them get into debt it is a sort of lever to heave them out of the mine; and if they have the advantage of it they look out for a job somewhere else.

8911. Is there abundance of men now to be obtained, or is there any scarcity in this district?—Since the year 1847 we have had a difficulty in getting workmen; there is such a feeling for emigration that there is scarcely ever an abundance of men.

8912. Do you use any particular kind of candles in your mines?—We use all sorts of candles, but good candles are the best and most economical that can be used.

8913. Is there any particular kind of candle that you use?—The best quality we find the cheapest to use.

8914. What do you pay as the wholesale price for the best candles?—The price of candles varies with the price of tallow; we are entirely governed by that.

8215. At the present time what is the highest price that you pay?—There are different prices, but we can get a very good sort of candle for about 5*s*. 9*d*. for a dozen pounds.

8916. Are the miners limited to a certain quantity of candles?—The tutwork men are limited to 2 lbs. a week per man; the tribute men may have as many candles as they choose if they are getting wages.

8917. What do you charge them for the candles?—Sixpence and sevenpence a pound; we have no fixed rule for every mine; we charge just enough so that the miners shall not waste the candles; there is no object to make a profit upon them.

8918. What is the highest price of candles at Prosper United?—Sevenpence a pound.

8919. What do you charge the miners for powder? Sixpence a pound.

8920. That is what the miners pay you?—Yes.

8921. What is the cost price of the powder?—Fivepence halfpenny a pound.

8922. What do the miners pay for club money?—Sixpence per man per month.

8923. Is that money paid only to provide relief in case of the miners receiving hurts?—That is for the club money; we do not understand anything but club money.

8924. Is there a separate account kept of the club money?—No separate account; that is the club fund.

8925. Is there any separate account kept of the club fund?—No.

8926. Is that club money used to relieve the miners when they have sustained any visible hurt and in sickness, or is it confined to visible hurts?—It is confined to visible hurts; we do not recognise any sickness, only visible hurts.

8927. There is no separate account kept of the club money?—None at all.

8928. Is it considered that the club money belongs to the adventurers, except that a man is to be supported when he has received a visible hurt?—Yes.

8929. Supposing a mine to be stopped, would any accumulation of the club money fall into the general funds of the company?—Yes, that would be the case, but we find that the 6*d*. contributed by each man per month is fairly self-supporting.

8930. I suppose it must depend upon the number of accidents that occur?—Entirely.

8931. What allowance is made to a man who has met with an accident?—Thirty shillings per month, and in the case of death we give 10*l*., and the funeral expenses out of the club if it is rich; we always give the 10*l*.

8932. You give that to the widow, and pay the funeral expenses if the club is rich?—Yes.

8933-4. In case of illness there is no allowance from the club?—If we consider that a man is ill from underground work, but men are so liable to be ill many ways that the doctors disagree as to how they have become ill. Upon that point very often these men are connected with a provident club as well as the mine club, and if they can lie upon both they will lie there for a long time

8935. What is the charge made for the doctors?—Sixpence a month per man.

8936. Is that paid for the doctor attending only to himself, and not to his family?—It is only the man; it has nothing to do with the family.

8937. How many doctors are there to each of the mines?—There are generally two, in some cases three, but generally two.

8938. Are the doctors appointed by the adventurers?—Yes.

8939. Do the men ever go to other doctors in preference to going to the mine doctor?—In cases where they are in provident clubs they can go to the club doctor, that is, the provident club doctor, and to the mine doctor too.

8940. With regard to the boilers, have you any stated time for cleaning them out?—That depends upon what mine it is. In some mines we cleanse them out every month, and in some mines we do not cleanse them out so frequently; it is according to the quality of the water; not only is it apparent to the eye, but as to the chemical ingredients that that water is composed of; it is dangerous to work too long.

8941. How do you ascertain that, by experience?—Yes, from experience; and we know what the action of the water is on the pumps and on the boilers.

8942. When you find that that has taken place, I presume the boilers are cleaned out oftener?—Yes.

8943. Who is it that attends to that matter?—The engineer is expected to watch over it; but, as a rule, we look narrowly into it. I look into that, and as a rule we pay proper attention to the boilers.

8944. Has any boiler explosion taken place during the last five years?—Yes, in Wheal Kitty.

8945. Did you ascertain the cause of the accident there?—There was no means of ascertaining it. We had only our own ideas upon that point.

8946. Was a man killed on that occasion?—No.

8947. What is your idea as to the cause of that accident?—The engine had been idle from morning till night. There was rather a longer stop than usual, owing to their having different repairs to do, and on the Saturday the engine went to work at about eight o'clock, and they had not worked many strokes before the boiler blew up.

8948. (*Mr. Holland.*) What part of it?—Every part of it; it went down as flat as could be, and through things 600 feet off. It was rent like so many ribands.

8949. Have you any means besides the cocks of ascertaining the quantity of water in a boiler?—Yes, there are water gauges to some of the boilers.

8950. Was there one to the boiler you have mentioned?—No; but I think that every boiler in the county ought to have a water gauge if they only knew how to work them. The difficulty arises from want of experience. If they are put in, and they do not answer, there is nothing wrong; but it is for the want of knowing how to deal with them. If they can use water gauges to locomotive engines, working at 120lbs. to an inch, surely they can to engines working 40lbs. to an inch.

8951. How many safety valves are there to the boilers generally?—There is oftener one than two.

8952. Is it not the practice to have two safety valves?—We only have two safety valves on the same branch opposite. I think that all the safety valves should be kept under lock and key, so that no one should have anything to do with them. I think that the boilers require a great deal of attention.

8953. Have you carried that out in any mine with which you are connected?—Yes, in some, but not generally.

8954. Is the cost of it much, or sufficient to prevent its being generally adopted?—Next to nothing at all—a few pounds. It is a new idea, and it requires a long time to change an old course.

8955. Did you ever know them to load the safety valves?—Yes; it is the exception where they do not do it.

8956. Do they not very often load them with very odd things?—Yes, with anything they can find. The point is, if the steam is got up a little fast, and if the agent sees that the steam is blowing away, he wants to know why that is so, and sometimes the valve is kept down to prevent the steam from escaping.

8957. (*Chairman.*) Is it generally the case that the boilers are not sufficiently looked after?—Yes; there are some places where a great deal of care is taken about them, but that is the exception, and not the rule.

8958. I believe that in many of the mines in the county the men change their clothes in the boiler house?—That is getting done away with now to a great extent.

8959. Is not that a dangerous practice?—Yes; and it is improper in every way, both for their health, and in all ways it is improper.

8960. Is there any charge made in your mines for the barber?—No; if the miners cannot shave themselves they may go without it.

8961. In paying the miners their wages what proportion do you pay in bank notes and what proportion in silver and gold?—We generally get from the bank about half notes and about half gold and silver.

8962. Do you think that the circumstance of paying the miners in notes induces them to go to a public house to get them changed?—They cannot change them anywhere else if they are paid in notes, as a rule.

8963. Have you observed that the men have suffered at all in their health from working underground?—Yes, they suffer from the air, and some constitutions are knocked up more easily than others.

8964. Do you think that the air is the principal cause that affects their health?—A good many constitutions cannot stand water, and there are some miners a number of hours in the water.

8965. You mean when they are working in wet mines?—I mean when they are working in wet ends, or in a shaft where the water is always two feet deep that you are standing in, or 18 inches.

8966. You think that that affects the health of the miners?—Yes; some men cannot stand it.

8967. In a close end where there is poor air, what means do you adopt generally for the purpose of supplying fresh air?—That depends upon circumstances; if it is near an engine shaft we should force air in by a machine from the engine, but if we could get water we should prefer a waterfall; if we cannot get either, we must have a fan-engine.

8968. And have it worked by a boy?—Yes, or by a waterwheel sometimes. We work the fan-engines with a little water-wheel, and they answer very well.

8969. How do you judge when the air is poor, and it becomes necessary to use artificial means?—More from the candle and from one's own sensations than anything else. You find sometimes that certain gases will hang about the bottom of a level, and a man becomes weakened; he feels it.

8970. Do you know anything about cold damp?—Yes; there are certain rocks that will give out more cold damp than others; there are some rocks that it is peculiar to; although the air seems fair enough for a candle, yet it is bad for the constitution.

8971. Have any means been adopted for the purpose of ascertaining the state of the air?—I have never seen any machine that has been used to ascertain the impurity of the air.

8972. (*Mr. Holland.*) Can you point out some places in mines where that cold damp exists?—It arises more from the soft porphyry or decomposed granite; that is just the same kind of ground as would decay wood rapidly.

8973. Is it equally bad in dry as in wet mines?—If you have got a large quantity of water the water would drive out the air.

8974. You stated just now that there was some air that was injurious to the miners, but in which a candle would burn; could you point out those spots?—Yes; where there is a soft decomposed granite and porphyry

CAMBORNE.

Capt. T. Richards.

5 August 1862.

it has more that effect than in other rocks that I have met with.

8975. Have you made any estimate as to the economy of labour effected by the use of the man-engine, or the value of the labour that is saved?—That is quite an estimate. There is no doubt that there is a very considerable saving; there is no question about that.

8976. Is it as much as a quarter?—I should think it was in many instances. If a man must climb up 300 fathoms he must save himself enough to be able to do that; whereas another man may work himself fairly up, and he may wear a coat to keep himself warm coming up by the man-engine; it is the last ounce, they say, that breaks the camel's back, and so it is in climbing.

8977. Have you formed any estimate of the value of cool air with reference to the quantity of work done; could not a man do more work in 60° than in 78°?—Yes.

8978. Could he do half as much again?—No.

8979. Could he do a third more?—I have never gone into that.

8980. The Commissioners have been informed that the miners work in 78°. Do you think that that is excessive?—I think it is when you get above 78° or 80°. It is not from that downwards so much, but it is above 78° or 80°; then there is a great loss of effective labour. It is unnatural for a man to work in an oven; it is too hot for a man to work in 80° for a great length of time.

8981. (*Mr. St. Aubyn.*) In a mine where a man-engine can be conveniently introduced, do you think it is conducive to the health of the miners?—No doubt of it.

8982. If a mine pays well, and is likely to go on for years, would it not also be economical to the adventurers to employ a man-engine?—Yes.

8983. The Commissioners were informed the other day, that in the Wheal Providence mines in Lelant, the cost of a man-engine would be repaid in less than two years?—If I were asked the question I should say no, because the depth of the mine is not great. The mine is only 120 fathoms deep, and I cannot fancy that it could make so much difference there; it is only in deep mines that they require a man-engine.

8984. With regard to ventilation, are you of opinion that a great proportion of miners' disease arises from bad ventilation?—I think that more of it arises from climbing; but there are some mines in which, although they are very well fit to work in, as far as the ventilation goes, there is no natural current. It is an unnatural atmosphere; for instance, you may stand on the surface at the edge of a shaft, and you will find that there is a nasty vapour that comes up, which you would not like to work in; but when you are underground you must work in that air, and that arises from not having the shafts frequent enough.

8985. Can you state to the Commissioners in a few words, what in your opinion are the best mechanical means of improving the ventilation in the Cornish mines?—That is a very difficult question to answer. The difficulty is to convey the air; but there are many means that might be employed in even so awkward circumstances. I think that if you have to force air in a distance, if you send it in by a pipe, that the area of your pipe should be in proportion to the length. For instance, it should be more in the cornucopian form; when you commence it should be large, gradually becoming smaller. If you take and use a four-inch pipe and you force air in for 100 fathoms you may burst the pipe; the air has no disposition to go on, and it becomes a fixed body, or it comes back again. The general working of the air in the Cornish mines is very little known compared with the collieries, because they have perhaps only one or two shafts; but they may have workings two miles off, and yet have a fair supply of air, while there is a large amount of gas arising.

8986. How may years have you been connected with mines?—For about 32 or 33 years.

8987. Are you of opinion that the miners, generally speaking, are now in better health than they used formerly to be?—Yes.

8988. To what causes do you ascribe their improved health?—I ascribe it first to this, that there is more attention paid to the comfort of the men when they come up from undergound. I think that it is very dangerous to come up from a deep mine, and then going anywhere to change. I think that they should keep up a moderate temperature until a man cools down; that I think would be a great advantage in the changing houses. I think also that the miners do not drink nearly so much now as they used to do.

8989. Is the ventilation of the mines improved?—There is more attention paid to ventilation no doubt.

8990. (*Mr. Kendall.*) At what depth do you think that a man-engine begins to pay well?—You must go back again. That depends upon the state of your finances, and the position of the mine; but I do not think there is any value in it until you get 100 fathoms below the adit.

8991. Up to that time you think that men can descend and ascend without much physical loss to themselves?—Yes, fairly well; a man climbs for a certain time and that does him no damage, it is the last fifty fathoms that does it.

8992. If you were to begin to work a mine, would you always have your shafts so formed that when you reached a certain depth you would be able to put in a man-engine?—As regards the beginning of a mine you come upon a very large question; if you begin you will go down in the course of the lode, and the lode sometimes will turn one way and sometimes another, sometimes north and sometimes south.

8993. Do you always in this neighbourhood go down with no underlie?—No; all about this district, the Camborne district, it is very hard ground, but out of it, in some districts that I am connected with, it is easier ground, and less difficult to work.

8994. I was thinking whether, where you have very fair ground, you would not sink a perpendicular shaft and drive a cross-cut?—We have no very fair ground; for instance, our granite is very hard, and our killas also is hard in places.

8995. Referring to the health of the miners, do they live much in their cottages here or not?—In towns I think they must.

8996. Do you think that that at all injures their health?—Certainly, if they have not sufficient sleeping berths it must be injurious.

8997. Is not that a matter that has been somewhat neglected in this county, and do not the men herd together in rooms, and sleep in too small a space?—Yes, and it is a great misfortune in many ways.

8998. It is pernicious both as to their morals and as to their health?—Yes, it is very bad altogether.

8999. You have had great experience in other parts of the county besides this immediate district?—Yes, more out of this district than in it.

9000. (*Mr. St. Aubyn.*) You are a western man, are you not?—Yes, but I speak generally of mines.

9001. (*Mr. Kendall.*) Do you think there is a want of good arrangements as to sleeping apartments of the miners?—Yes, I think there is a want of that.

9002. (*Mr. Davey.*) What is the deepest mine which you manage now?—160 fathoms below the adit.

9003. Do you use a skip there?—Yes.

9004. Do you prefer a skip at that depth to kibbles?—In what relation do you speak as to the skip; do you mean for drawing up the stuff?

9005. Yes?—If you have any shaft not a vertical shaft the skip is the most advantageous, because you can put in wheels to ease off the friction, and there is a great advantage in a skip over the old mode of drawing. If you have a verticle shaft and you divide them there is no harm, because the chains do not foul, but if you draw vertically the nearer you can keep it to the vertical the better.

9006. Do you think that you can draw as cheaply

by kibbles as by the skip?—We cannot, I am quite satisfied of it.

9007. Suppose that your mine was 100 fathoms deeper, what would then be the result; which would be the best, the skip or a kibble?—There is no question that the skip is the most advantageous anywhere; it must only be a strong prejudice which is opposed to it. When you come to work them there cannot be two opinions that the skip is the most advantageous; it is a common sense thing. Here is a box working in a guide; it does not vibrate or strike against the ground, or anything of that sort; there is no swinging to and fro; when the kibble strikes anything going at a great velocity there is sure to be something wrong.

9008. I suppose that you have tried many experiments as to the best mode of ventilation?—Yes, a good many.

9009. Did you ever try drawing out the foul air, instead of forcing in air?—I have tried both with a double set of pipes.

9010. Which do you think is the best?—I generally make it a rule to take up my air in a good place. Say, for instance, that I was going to drive a 100 fathom level, I should not go out to the 100 for the air. I would go to the 70, or 80, or 90. I would take up my air where it is good, and send it on; it is of no use to take the old air again. I have used lime (which I have found a very good thing) in the mouth of the pipe to improve the air.

9011. You have not mentioned about withdrawing the foul air, how did it answer?—It is a very good plan. I like extracting the foul air, but then I would never take up the warm air to send it back again.

9012. How did you manage to extract the foul air?—Simply by a pump from the engine worked by a rod. We have a double machine at Treloweth, for instance, a 30-inch cylinder, with a piston, and there is a top and bottom valve.

9013. (*Mr. Holland.*) What stroke has it?—An eight feet stroke.

9014. (*Mr. Davey.*) Do not you find generally speaking that as a new principle they sink the shaft after a certain depth upon the lode?—A question was asked about commencing a mine. In commencing a mine we sink upon the lode, but when you carry out a mine in a proper manner you after a while come to find that you must go on the underlie, and as soon as you can you get away upon the underlie, because whatever you sink vertically it is dead ground. You can get nothing out of it, and it takes a long time, and will cost more as a rule.

9015. Do you not think that is a new principle which has lately been carried out of sinking diagonally instead of perpendicularly. Formerly after you had worked a mine a certain time you would sink a great depth and then cross cut?—That arose from this cause: in the old days a large amount of attention was paid to drawing, and to draw well they could only draw vertically; but since skips have been introduced you can draw diagonally, or at a change of angles by having proper sheaves put in, and you save a great expense of dead sinking.

9016. And the present mode is an improvement in the working of mines?—Certainly.

9017. (*Mr. St. Aubyn.*) One witness has given it as his opinion that if the underlie was not more than two feet in a fathom it was more advantageous to have a kibble, but that if it was more than two feet it was better to have a skip. Is that your opinion or not?—I consider that when you go off the vertical line you you should have a skip.

9018-9. You would have a skip directly you go out of the perpendicular?—Yes, but there are very few of those cases. In a skip road your skip must be kept in good order, or you cannot work at all, whereas your other shaft will go on working until you cannot go on working any further. If you take the best means of drawing stuff in the country, in the collieries they always work guides to their vertical.

9020. (*Mr. St. Aubyn.*) Why should you not have guides in a vertical shaft?—They are advantageous in a vertical shaft. A skip is advantageous in a vertical shaft, it having less friction.

9021. (*Mr. Kendall.*) It is a great saving in a vertical direction, but greater still when you go down in a slant line?—Yes.

9022. (*Mr. St. Aubyn.*) In any of the mines of which you have the management, do the men use the skip to come up with?—No; we do not allow it. I think it is unsafe unless a shaft is set aside for it entirely. I do not think that stuff drawing and man drawing should go on in the same shaft.

9023. (*Mr. Holland.*) What danger do you apprehend from that?—In drawing stuff, with all the care which may be used, stones may fall into spaces, and may fall upon the men coming up.

9024. (*Chairman.*) Do you think that it would be practicable to make a skip a means of ascent and descent for the men in the mines?—I think that the drawing of stuff and the drawing of men are two separate things.

9025. Supposing that you had a shaft, instead of setting it apart for a man-engine, could not you set it apart for a skip to draw the men up with, the same as in the collieries?—It would not be so well to draw with a skip as with a man-engine.

9026. Do you think that it would cost more per day, or cost more in the erection of the machinery for a skip?—A good deal depends on the shaft.

9027. Supposing that the shaft is adapted for a man-engine or a skip, and that you put a skip, would not that be a cheaper cost in the first instance than putting in a man-engine?—It would be cheaper, but I do not think that it would be so safe.

9028. (*Mr. Holland.*) What danger do you apprehend?—From the breaking of the chain.

9029. If you can carry up half a ton of ore, cannot you carry up 2 cwt. of men?—If you carry up half a ton of ore and it breaks, it goes down; if you take up a man or two and they are killed, there is an end of it. You take one end of the question, namely, what is in the bucket, but you must bear in mind that in deep mines we may have three or four tons of chain drawing; it is not the weight that is in the bucket that breaks, it is the chain's own weight. If you are drawing say 250 fathoms deep you have three tons of chain; it is very often its own weight that causes it to break, and not the difference of weight of the kibble of stuff or of men.

9030. (*Chairman.*) Could you not substitute a wire rope for chain?—I am not so favourable to wire ropes, they answer very well in some places.

9031. What is your objection to them?—In the first place, in copper mines a wire rope will precipitate very fast.

9032. (*Mr. Holland.*) Will it do so if well covered with grease and tar?—They are always well covered till an accident occurs, and then there is a little bit not covered.

9033. Are those the only dangers which you fear, namely, bodies coming down the shaft and falling on the head, and the rope breaking?—Yes.

9034. If those could be effectually guarded against, you would see no objection?—Not at all; it is only a question of safety. I fear the stuff lodging about the shaft and the chain breaking.

9035. Do you find that the use of lime in the air pipe makes the air decidedly purer and pleasanter?—In my experience it has done so.

The witness withdrew.

Captain JOSEPH VIVIAN examined.

9036. (*Chairman.*) What is the principal mine of which you have charge?—North Roskear.

9037. Have you charge of any other mines?—I superintend North Crofty, a mine adjoining, and South Condurrow.

9038. I think that you have sent in a statement of

CAMBORNE.

Capt. J. Vivian.

5 August 1862.

the number of men employed?—Yes; a statement of the men and of their ages.

9039. What is the youngest age at which children work on the surface?—I should think some of them may be as low as about seven years old; they are employed at little light work.

9040. I suppose they are sent to that as their parents cannot afford to send them to school, and they are obliged to be sent to work?—Yes; as many as can well afford to do it send their children to school. We have a school here, and we support them from the mine.

9041. The young children of the families of miners employed with you are sent to the school?—They go to the British School.

9042. And the fees of the school are paid by whom?—By the mine.

9043. At what per head?—We pay, I believe at present more to the school than we have children there. A penny a week is our pay for each child.

9044. Is there any charge on the miners for the support of the school?—A great part of it is from the miners. There is a club, but the club in reality is provided by the adventurers. It is considered as a part of their cost of materials, and so on, although it is deducted from the men. There are many things that we deduct from the men to make them as economical as we can, but they do not really pay for it.

9045. The club money is not merely for visible accidents, but it also provides schooling for the children?—Yes.

9046. What is the amount of club money which the men pay?—Our club money is about 6*d.* a month per man.

9047. That, according to the rules, is for visible hurts?—Yes, for visible wounds.

9048. Is there no extra charge beyond that for the schooling of the children?—No.

9049. How are the fees which are paid to the school charged against the adventurers?—The club is deducted from the men the same as any other material with which they are supplied. It does not appear before the adventurers as a charge. The charge is for breaking a certain quantity of ore, or for excavating a number of fathoms of ground, amounting to a certain sum of money. The men's materials, powder, candles, clay, nails, and the various other things are furnished, and club and doctor. They pay 6*d.* to the doctor as well as to the club. Then the doctor takes them on all occasions. Formerly it was found by the surgeon that not only wounded men called upon them, but that men called upon them for colds, sprains, and one thing and another, and 15 or 20 years ago we altered the amount from 3*d.* a month to 6*d.*, in order that the doctor should attend on all occasions.

9050. From what fund does the money come for the children who are sent to school?—That is deducted in the club account. We will suppose that so many people may have been wounded, and so much money paid, and we finish with the school charge. We deduct 6*d.* for club, and 6*d.* for doctor, amounting to 1*s.* a man.

9051. Do the doctors attend the families or only the men?—Only the men.

9052. Have you any charge for the barber?—No, we do not deduct for the barber at our mines.

9053. How are the doctors appointed?—The doctors are appointed generally by the adventurers at a public meeting. There is some little objection occasionally, and some men believe that they ought to have the fixing of the doctors for themselves, and I have thought so too. If there is a doctor's fund to draw from, and if a man is wounded, let him say for himself whom he would like to have, because one man would like one doctor, and another man would like another.

9054. You think that that would be desirable?—It would be desirable if it could be carried out. We have nothing to complain of in our surgeons. Some men sometimes live miles apart. Many of our men live three miles from the mine.

9055. And it is often a long way to go to a doctor?—Yes; and then they like the doctor that they have had in their family.

9056. Would the sum charged against the men for the doctor be sufficient to pay the salary of the doctor if they selected their own doctor?—I think it would. I think that we could do it upon an equally small scale. Formerly we used to have from 1,000 to 1,100 people for many years at North Roskear, and now there are only about 500 or 600 altogether.

9057. How would it do if there were doctors and dispensaries for a certain district, combining small mines with large mines?—There are the same surgeons now to a great many of the mines, and, as far as I know of them, altogether they are very attentive men indeed, and very able men in the profession. At least I believe so.

9058. You have stated the deductions from the men. Amongst other things, candles are deducted. Do you use any particular kind of candle?—No; they are all tallow candles. We have been using composition candles from a patent candle maker's, Palmer's. The men like them very well.

9059. Is there any advantage in your opinion in those candles over the others?—I do not know that there is. Men in close places prefer them; they give a sharp smaller light, and they do not make so much smoke, but then they are not so handy for carrying through shafts which are wet, or where there is a strong draught blowing. If they once go out, they cannot be blown up again, which can be done with an ordinary candle. If Palmer's candle goes out, you must have somebody to give you a light, or resort to your match-box.

9060. Is the price about the same?—Yes.

9061. What is the wholesale price now?—5*s.* 6*d.* per dozen.

9062. What is the deduction from the men for candles?—We generally deduct considerably more than we pay.

9063. How much?—I think we are at present charging 50 per cent. more than we give. We make that sort of general rule to charge 50 per cent. more for everything, but I believe that at present we are charging 9*d.* per lb. for powder and 9*d.* per lb. for candles. We do not alter for a trifle when the price goes up and down. When they take a set they understand what they will have to pay for drawing, and candles and nails, and so on. We charge some of the tributors for timber, that is, for planking timber, not for timber for securing the ground; it is done in order to make the men as economical as we can, that is the main object, otherwise you might have to deliver more from the store, because it is all the adventurers' store; it is the same with the club and doctor. It is always looked at what a man has really carried away in cash.

9064. In the estimate of the average wages of the men, do you take into account the earnings of the tributors and tutwork-men and captains together or separately?—We never take in the agents at all. If we are called upon to show the average getting, we show the average tutwork-men's getting and the average tribute-men's getting. We generally calculate that the tribute-men get a little more than the tutwork-men.

9065. Could you furnish for the month's pay the average of the tutwork getting?—Yes, we look over it ourselves. There are the number of men and boys and the cost. When we have bargains to let we look over the thing, and we consider what the cost will be in breaking a fathom of ground, and how fast a man can break it, and what he can do it for.

9066. What would be the average wages of the tutwork-men now?—The average wages of the tutwork-men now in this neighbourhood are somewhere about 3*l.* 10*s.* per man.

9067. That is not saying that they all of them get that amount?—No; the first-class men get 4*l.* 10*s.* and 5*l.*, and so on, generally, and the second class a little further down, and the third class a little further

down still. There are many men who perhaps will never get more than 55*s.*

9068. Are you now alluding to the net earnings?—Yes, after everything is paid.

9069. So that the wages of the men vary very much?—They vary very considerably; it is the same thing with tributors and tutwork-men. Some fine fellows will speculate upon tribute, and will do a vast amount of work. If you average them for the year they will always do well; others will not do well; some will not work and some cannot work.

9070. And some get a bad pitch?—Yes, exactly like a company of adventurers working a mine.

9071. In getting a bad pitch, although a man may be a good man he may not get anything for four or five months except subsist?—He gets subsist always.

9072. How much subsist do you advance to a tutwork-man?—We do not profess to advance to a tutwork-man, though we do it occasionally. We do profess to advance to tributors; the tutwork-men wait for the pay day and take up their money as they like.

9073. What do you advance to a tribute-man?—About 2*l.* a month, or a little more; if he is a man worth notice we do not let him have less than 2*l.* a month, and sometimes a little more. There are men who call themselves tributors whom we do not call tributors at all; they have a pitch; we would rather have their room than their company; and we do not advance to them to much extent.

9074. A tributor who has to exist on subsist with a large family, probably gets into debt in those four or five months?—We have a man now at North Roskear, a first-rate old man, who has been working there for 30 years; the last two years he has always been speculating, and has done badly. I said to him the other day, "You are doing badly." "Yes," said he, "I never had such a long run before, but I shall make "it up again soon." I said, "You have not done "badly upon the whole; you have been here from a "boy." He is worth 200*l.* or 300*l.* probably; he has one or two cottages, and keeps a cow, and so on; we never let him go upon less than 2*l.* 5*s.* a month, though for a long time he has not earned any money.

9075. What is that man in the mine's debt, should you say?—About 25*l.*

9076. (*Mr. Holland.*) Is that quite safe?—No, not a farthing of it is safe. We rely upon the man as a speculator.

9077. (*Chairman.*) As you have known him so long a time as a good man you have done it?—Yes; and although a tributor may be in debt to the mine, yet the proportion of ore which belongs to the company being in most cases more than the amount of the debt the mine will still be a gainer.

9078. (*Mr. Kendall.*) Suppose that after a while the man gets a good start?—We keep back the money.

9079. The whole of the money?—That depends upon circumstances. The man that I mention was once in debt, with two others, 70*l.*; he got money in two months and paid every farthing off; they got 100*l.* each and paid their 70*l.* that they were in debt.

9080. First of all, I understand that you have a chance of being repaid in full, and if you are not repaid in full you are able to prove that on the whole, even though the men are in debt to the mine, yet taking the profits which they make to the adventurers, there is still a balance in favour of the adventurers?—Yes.

9081. (*Chairman.*) Taking an average of the men's earnings, it does not give you any idea of what is really earned by the different tutwork men and tribute men. The average does not give you the real amount earned by the separate men?—No.

9082. Some men therefore are well off, and some men are not well off?—Precisely so; and more particularly so with the tributors; some of them get a great deal of money, and others are speculating; a pitch turns out badly and they do badly.

9083. I suppose that in consequence a number of men get into debt with small shops?—We do not interfere with the miner's private business.

9084. But that is the consequence?—Yes; very often a great many get in debt to the small shops who ought not to do so; they are living faster than their means will allow, and faster than they have occasion to do.

9085. Do you think that the packmen induce the families of miners to get into debt?—Yes, and other people too.

9086. You think that the packmen going amongst the miners' families are a great evil?—I should suppose that they may be, but I think that they keep the shopkeepers in check, for they sometimes sell things a little below; they have no establishment to keep up.

9087. (*Mr. St. Aubyn.*) But they give credit?—They do.

9088. (*Chairman.*) Have you any rule as to your boilers being regularly examined?—I do not know that we have any regular rule; the boilers are tested occasionally.

9089. Have you ever had an explosion?—No; if the engineman does his duty properly it is impossible that an explosion can take place. The breaking out of a boiler is of little consequence, but the blowing up of a boiler is a very serious affair; and if the engineman sees that the feed is as it should be the boiler cannot explode. If the breaking out of a boiler happens we must patch it at once.

9090. Is the breaking out of a boiler a common thing?—It happens when the boiler gets old. The engineman says, such a boiler is getting leaky.

9091. When new mines are started are not many second and third hand boilers purchased?—Yes; the engineer has to examine them to see that the boilers are perfectly safe.

9092. Have you any water guage to show the amount of water in the boiler?—Yes, always; the engineman can tell exactly where the water is.

9093. Without trying the cock?—Yes, he has his gauge; we work about six inches of water upon the tube, and he can tell if the water gets one inch below.

9094. Is that generally the case in your opinion?—Yes.

9095. (*Mr. Holland.*) What sort of a gauge is it?—There is a swimmer gauge.

9096. Not a glass gauge?—No, we always depend upon the swimmer acting; many have glass gauges.

9097. (*Chairman.*) Have you more than one safety valve?—There is a safety valve for every boiler.

9098. Only one?—Yes, to each boiler; the boilers are connected, we do not depend upon one.

9099. With respect to roasting the ore, you collect the arsenic?—Yes, from the tin ores.

9100. Does it rise up in a vapour?—Yes.

9101. Does the vapour ever escape?—Not with us; we have houses sufficient from the calciner to the stack to contain 300 tons of arsenic, and though the price is now low it pays well for saving. The length of the flues from the calciner to the stack is from 250 to 300 yards.

9102. So that none of the arsenic escapes by any chimney?—None of any consequence to do any mischief; but sometimes where the stack has been too close to the calciner it has been the case; but people have got more awake to the thing. We have to reduce the tin; it is mixed up with arsenic, and copper, and iron pyrites, and one thing and another.

9103. Have you ever heard of any person suffering from the arsenic fumes?—No; all our people are very healthy people, and they work at the burning houses. We had a dirty girl at one time, and a complaint was brought on and it killed her; but it was entirely the fault of the young woman herself.

9104. (*Mr. St. Aubyn.*) How many years have you been connected with mines?—I am now 70 and I have been in the mines ever since I was 12 years old.

9105. Nearly 60 years in fact. Is it your opinion that the miners as a class are more healthy now than they were when you began?—Yes, considerably more so.

9106. From what cause?—I think that one great

CAMBORNE.

Capt. J. Vivian.

5 August 1862.

cause is that formerly they never carried down provision with them, nor water; but in the last 20 years there has always been a fresh supply of water brought to all the mines from the wells about; it is first rate water, and they have it sent down to them, or they carry it down in their canteens, it depends upon the depth that they have to fetch it, and they carry down their dinner with them. I think that is one cause of the improvement. And I think that the mines are now better ventilated than they formerly were. I also think that the footways in the mines are kept better than they were; they are kept away from sharp draughts, and the water is kept away from them. They are all drier, and there is every accommodation. They have a comfortable house, with a constant supply of warm water running through it, for them to wash in when they come up. Here every man keeps his own soap and towel, &c. They are all expected to go away clean; they wash themselves clean, and they wear better clothes than they used to do; they used to be without stockings and things of that sort, which is now out of the question. They went away dirty, the same as the German miners do; but now it is altogether a different thing, and I think that that has improved the health of the people very considerably.

9107. Do you think that the mines are as well ventilated as they could be?—All the mines that I am acquainted with are well ventilated, and so are all the mines about here, I should say for a certainty, for miles and miles, and, as far as I know, farther. I think that the Cornish agents have studied the ventilation of mines almost as much as anything connected with it. You will now find that 200 or 300 fathoms deep in the North Roskear mine the air is as good and as pure as it is in this room. We throw it down. We find that one shaft serves for the down draught and another for the up draught. Of course, when you get deeper you will get hotter as you get in, and some of the men in deep levels will have to work in hot places, and sometimes, rising against a shaft, those places will of necessity for a few months be warm and not so healthy as airy places.

9108. Could you suggest any mechanical contrivances for making the ventilation better than it is now?—I do not know that we could. In our mine at South Condurrow, where we have only one shaft, a pitman came down to me the day before yesterday and said, "The air at the bottom has got uncommonly fine, and I think it is bad." I said, "You have a large bellows and a pipe and every-"thing to it. In how long could you do it?" He said, "I could do it in two days." It is now working and sending down a stream of pure air. If we can command a draught we do so, and if not we use the bellows or a fall of water.

9109. Are you of opinion that where it is possible and convenient to introduce a man-engine it is conducive to the health of the miners?—I should always have a man-engine if it could be had conveniently, ut in some places you cannot have it.

9110. The convenience or the possibility of adopting a man-engine depends in a great measure upon the paying of the mine, does it not?—Yes, upon circumstances; you may have a shaft that you can part with in old mines which have been worked a long time. They frequently have a shaft that they can part with if they have the means of putting up an engine and having everything complete; then it is done; but in other cases, where you work hard and cannot make the two ends meet and have not a shaft to part with, it cannot be done; the very thing itself would sack the mine.

9111. Supposing that you could spare a shaft to adopt a man-engine, how deep would you go before you thought it necessary to give up the footways?—I should not trouble myself about a man-engine if the mine were only 130 fathoms deep, if the ladders were well arranged; sometimes they are not well arranged, they are too perpendicular or too flat. A proper pitman will know exactly how to arrange the ladder so as to keep the whole human frame in a proper position.

9112. You think that if a man does not hurry himself he can climb 150 fathoms without injury to his health?—Yes, I find no difficulty in climbing 200 fathoms.

9113-4. The length of the ladder depends upon the width of the shaft?—Yes; if you have a roomy shaft you may make your ladders longer, though I am never an advocate for making them long. Our ladders are generally about 4½ fathoms, but in some shafts which are a little sm aller we are obliged to have them a little shorter.

9115. Are the staves of your ladders 10 inches or a foot?—Ten inches.

9116. You consider that better than 12 inches?—Yes.

9117. It is not so fatiguing?—No; a man cannot fatigue himself so much, and he cannot injure himself so much with a 10-inch ladder as he will with a 12-inch one.

9118. Have you found any opinion as to the advisability of lighting mines with gas?—I should not think that that would be practicable; if a man is working with ordinary tools he is frequently shifting his light; he is driving one way and then another, and he shifts his candle in a moment to see exactly what he is doing.

9119. You have never had any practical experience of gas in a mine?—No.

9120. North Roskear was originally a copper mine?—Yes.

9121. But you have lately come into tin?—Yes.

9122. Do you observe any change of temperature in the ends when they come to the tin?—No, I think not, visibly. In the eastern part of our mine we have a place or two remarkably hot, and what the reason of that is I do not know; there is neither copper nor tin in the ends at present, but the water is hot and the air is hot.

9123. We have had evidence at St. Just that the copper was a great deal hotter than the tin, and that the men where they were working always knew when they were approaching copper by the increasing heat in the ends; have you observed anything of that kind in North Roskear?—No, never.

9124. What level is it where you find it so hot now?—At 140 fathoms below the adit, that is to say, 160 fathoms from the surface; we are 270 fathoms from the surface in the deepest part of the mine.

9125. In fact, that is hotter than the deepest part of the mine?—Yes, much hotter.

9126. Can you account for it at all?—No. It is near to a large cross course, which is the boundary of North Roskear and North Crofty.

9127. (*Mr. Holland.*) Is there much water?—Yes. We always find the air and the water of the same temperature.

2128. (*Mr. Davey.*) Have you any level coming under this 160 fathom level?—No.

9129. How far is there any level behind it?—I should think that the nearest level is something about 40 fathoms behind it.

9130. How far is this 160 fathom level from the bottom level?—The 160 fathom level is the bottom level in that district, the Crofty part is only to the 160 fathoms below adit.

9131. Is that the bottom part of that lode?—That is the bottom that we have worked down to in the eastern part of the mine. Then there is a great cross-course between. We have no communication below the 120 fathoms between our eastern and western district.

9132. Then you have never tried until now to follow the hot water in this district?—No.

9133. Do you know any instance where the hot water has been followed in this district?—No, I do not know that we have had much hot water about this district; that is the hottest place that I have seen in the parish at all.

9134. You have mentioned that you consider that

the health of the miners generally has been improved very much? —Yes.

9135. Do you recollect when you were a young man a number of men who went about the town with great coats on complaining of the miners' disease?—Yes. I recollect a disorder which seems to have gone from the country, men in decline. I should think that nearly 50 years ago there were a great many young fellows that went off in decline.

9135*a*. You used to see them about the streets in the summer time with great coats, laid up with the miners' disease?—Yes.

9136. You do not see anything of the kind now?—No, not at all.

9137. With respect to the boilers, you have stated that you always test them. In what way do you test the boilers?—We do not test the boilers, they are tested before they are put in; we have no means of testing them after they are in their places. They are tested with hydraulic presses before they are put in; that the boiler-makers arrange to do.

9138. In case of a leak, or anything which has affected a small space in the boiler, it will not cause an explosion but merely a break out?—Exactly so.

9139. Do you charge men for planking?—Yes, and for nails; not with the view that they shall be short of anything, but to make them as economical as we can.

9140. If you are driving a level, and it requires timber, do you charge the men for that timber?—No, it is merely the tributors. We do not charge them for putting in air sollers or anything of that sort.

9141. You keep a separate account for your club?—Yes, we keep our club account with the bank separately.

9142. How does it stand just now?—I do not know exactly. We have no great amount in the bank, because if at any time we should be short, we should say to the adventurers "We are short," and we should get a trifle to put to the club.

9143. Do you ever refer to the adventurers for assistance?—Yes, and we have never found it refused.

9144. Do you use any acid in cleansing your tin?—No, we have never used any.

9145. Do you suppose that any arsenic could arise from washing the tin, so as to injure the health of any people dressing it?—No, I think not; all the people are healthy enough. There is not a healthier set of miners in England than our men are, belonging to the calciners and the burning houses; and we keep girls by daytime and men at night to assist at the calciners'.

9146. (*Chairman.*) Do you use a skip or a kibble for drawing?—In some cases one and in some the other; we prefer the skip wherever we can use it.

9147. Do the men ever go up in the skip?—Yes, but I do not like it. We have not any wire rope, but if we had a wire rope which could be laid on, I would as soon go up in a skip as not; but I do not like it with a chain.

9148. A properly constructed skip, with a safety stop and a wire rope, you would consider sufficient?—Yes.

9149. (*Mr. St. Aubyn.*) Why do you make a difference in your mine between a skip and a kibble?—On account of the different inclination of the lode we cannot get the skip to act exactly. Sometimes it inclines to the north, sometimes to the south, and at other times is vertical, and the crookedness of the shaft makes it impracticable to work a skip.

9150. Do you not consider it more advantageous to have a skip in a diagonal shaft?—Yes.

9151. Could not the diagonal nature of the shaft be obviated by proper sheaves?—Yes, but sometimes we could not afford to do it; we have not the means.

9152. If you had the means it would be better?—Yes; a skip is as preferable to a common kibble as good living is to bad living.

9153. Would you have a skip in a right-down shaft instead of a kibble if you could?—Yes, skips are as profitable there as they are in any other place. You can have proper guides, and you may draw as fast as you like, and one never interferes with the other; but with kibbles, they will interfere and do a vast amount of mischief. We had an accident the other day by one kibble coming down upon the other, and it broke both chains.

9154. (*Mr. Davey.*) Supposing you had a very deep shaft, say of 280 fathoms, would that alter your opinion as to having kibbles or skips?—I would have a skip by all means in the world there, and wherever I could put it in. When I was at the German mines, I saw that they used a skip and wire rope, and when I came back I was asked what I thought of the German miners, and I said that we are better practised miners than they, but they beat us in drawing the stuff.

The witness withdrew.

Mr. ROBERT HART PIKE examined.

9155. (*Chairman.*) I believe that you are purser of several mines?—I am.

9156. Will you name two or three of the mines?—Carn Brea mines and Cook's Kitchen mines in this neighbourhood; Huel Kitty (St. Agnes) and Wendron.

9157. Do you think that in paying the men the payment of a large part in notes is any inducement to go to the public-house to get them changed?—No doubt of it; that is, where a number of men are paid together, and the sum of 5*l*. exceeds the amount payable to any one of them. Then, of course, it is necessary to obtain change, which I believe is only obtained at public-houses, and of course it necessitates spending a portion of money.

9158. In your opinion would there be any possibility of paying the tutwork-men other than once a month?—I should consider that it might be done. I believe that it is done in many of the foreign mines—the St. John del Rey and most of the mines in Cuba, and various other places.

9159. Might not a more frequent payment of wages in a great measure prevent the men from getting into debt?—It would obviate the necessity of it in a great degree.

9160. In carrying out any improvements in the working of mines we have been told that there is some difficulty on account of the stoppage which it would occasion in the works. Would not also part of the receipts of the adventurers be stopped for that time?—That is a cause alleged for the non-carrying out of very many improvements in mines. I have found it given as a reason and an excuse in many instances.

9161. Therefore, to those who look for a permanent investment in the mine it is a disadvantage?—It is a disadvantage, because, unfortunately, mining is not looked upon generally as a permanent investment. The greater number of people engage in mining simply with a view of raising a profit upon the sale of shares. The consideration is not so much to work a mine to a profitable issue.

9162. Does not that system tend to prevent improvements which would benefit both parties?—Yes, no doubt of it. Mines so got up have not in view the carrying out in a miner-like manner the operations of the mine; but a mine in full and fair course of working is frequently prevented from having the benefit of measures which would improve the revenue of the concern, by the unwillingness of the shareholders, even though they are bonâ fide ones, to submit to any temporary reduction in their dividends.

9163. A reduction which would send down the value of the shares?—Yes, that is the idea, and that if it was necessary to realise, they would have to make a sacrifice.

9164. Those improvements would tend not only to the advantage of the adventurers, but also to the health of the men employed?—Improvements of that

CAMBORNE.
Mr. R. H. Pike.
5 August 1862.

nature might be adopted, and it is generally improvements in reference to the shafts which would facilitate the miners going up and down, but they would of course have the objection on the part of the shareholders that they would diminish the amount of the returns for some time.

9165. Is there anything which you could suggest to the Commissioners as likely to tend to improve the condition of the miner?—I am not a practical miner myself, but having a large connexion with mining, and having heard the opinions of many of our best mining men expressed, the greatest improvements would be in introducing facilities for the men getting up and down without the fatigue of ladders.

9166. You think that that should be more general than it is at present?—Yes.

9167. Have you any experience, from your knowledge of mines, as to the men suffering from any want of ventilation?—It sometimes happens that when it is necessary to communicate from one point to another, for the purpose of ventilation, the miners have to work in a very close place and bad air, in which it is hard to keep a candle burning, and a difficulty in breathing is experienced.

9168. Then if any additional means could be adopted while that necessary operation is going on of supplying fresh air, it would be very desirable?—It is done if the cross cut or communication to be made is an extensive one, or if there is a great deal of ground to open, then, of course, they introduce artificial means by pumping air; that may be done to a great extent, but if they are driving for merely a few weeks or a month they get on without it. The men bore the ground for blasting, and when they set fire to the fuze they leave their work, and perhaps it would take several hours before they could return to the place, on account of the smoke.

9169. And I suppose they are paid more?—Yes. I do not mean to say that the men get higher wages, but they work fewer hours, and the wages of course must be made up to them.

9170. Are you purser to any mine in any other part of the county?—At Wendron and in St. Agnes.

9171. Is the rate of wages less in St. Agnes?—Yes, there is more competition; there are more labourers in proportion to the labour.

9172. You think that that is the reason?—Yes, decidedly. I remember the time when you would have to pay more at St. Agnes than you would pay here, because for some time previous the mines had been poor, and very few men had been employed, and consequently they had to migrate from the place, and afterwards when the mines were again put on there was a difficulty in getting men, and men had to be brought from here to work the mines in St. Agnes. Now the population there has increased, and there are more men than are required, and they prefer remaining at home where they have a house or a family and working at lower wages, to coming away and getting more.

9173. Therefore it prevents the earnings over Cornwall being equalized?—Yes.

9174. Have the miners in St. Agnes an occupation besides working in the mines?—Not so much at St. Agnes, I think, as in Wendron; in Wendron they have; there is scarcely a miner there who has not a little piece of land with which he engages himself in the evening or the afternoon, and when he is not at work in the mine. I am not quite so familiar with the St. Agnes men as with the Wendron men, but I know that it is very common with the Wendron men, and I believe also at St. Agnes.

9175. How are the doctors appointed, is it by the adventurers?—By the adventurers, by a majority, or in a company which is under the management of a committee of the adventurers, it is done by that committee.

9176. The men have nothing to do in the mines with which you are connected with the appointment of the doctor?—No; but if they expressed themselves strongly against the appointment of any doctor no doubt he would be changed.

9177. Are the doctors appointed for life?—No.

9178. During good behaviour?—Yes.

9179. They are not re-elected?—No; they remain in office until they are dismissed.

9180. In the mines with which you are connected is there one uniform system with regard to the club money?—Yes.

9181. Is a separate account kept of the club money in each mine?—Yes.

9182. Is that looked upon as an account for the men, or an account for the adventurers?—It is looked upon and always treated, I think, as belonging to the adventurers, on the occasion of a mine being abandoned when the club fund ceases to be held.

9183. And it is regarded as assets of the adventurers?—Yes.

9184. Has that ever been disputed?—No; I never heard of a dispute. There have been frequent cases of winding up mines, and the money has been treated as an asset of the mine.

9185. What has been the largest amount of it in winding up the mine, in any mine that you have been connected with?—In any mine that I have been connected with it has always been very irregular, because I have always recommended liberality. In the Carn Brea mines, which are the most extensive mines in Cornwall, the club fund several times has 100*l.* in hand, but it is more frequently 50*l.* or 100*l.* in debt.

9186. Does that arise from there being more accidents, or from your applying that club money otherwise than to visible hurts?—We apply it to pensioning off old men who are unable to work any longer on the mine, who have been there for many years and their money is spent; we always make them some allowance, and we are not particular about the injury or the illness which is occasioned by the nature of their work, we treat an illness occasioned by working in the mine as a visible hurt. Then, again, out of the club fund we bury the men; if a man dies from an ordinary illness, not at all connected with his duty in the mine, we always pay for the coffin; any man working in the mine has his coffin from the mine, and that is always charged to the club at Carn Brea.

9187. Is any allowance ever given to the widow?—Yes; we generally allow 10*l.*, and sometimes more, never less than 10*l.*

9188. That is from the club money?—Yes.

9189. What allowance do you generally make to a man from the club money?—1*s.* a day.

9190. With regard to the candles, is there any particular kind of candles which you use?—We use those which we think are best adapted to the particular ground, or the nature of the air in the place.

9191. Do you use Palmer's?—Yes; we use some of Palmer's. In deep places, or in draughty places, I believe the men do not like them, they will not blow in again if they blow out.

9192. What is the charge for the candles to the men?—We charge 8*d.* a pound.

9193. And the same for powder?—Yes; there is a considerable profit charged upon everything, but the reason for that is to prevent the men wasting the articles; even now, with the charge which is made, if the men are not carefully watched, they will take out a great many more candles than they really want, simply to sell them to make a little ready money.

9194. (*Mr. Holland.*) To subsist on?—Generally for beer money.

9195. (*Chairman.*) What becomes of the profit on those candles?—It goes to the adventurers. In making up the account of a tributor or a tutwork-man, he is charged so many pounds of candles as a deduction from his earnings.

9196. (*Mr. St. Aubyn.*) Sometimes as much as 50 per cent.?—Yes, but that is all reckoned in. It amounts to the same thing. It is simply a check upon a man against his wasting too much. The estimate of the net earnings of the men is 3*l.* a month; it is just the same as with the smelters, they take 21 cwt. of ore for a ton.

9197. (*Chairman.*) We understand the earnings of

the men are generally calculated upon an average?—Yes.

9198. There are a large number of men of course who never come up to anything like that average?—Yes. I should say that fully one third have less than one third of the amount of the average; that is to say, for some time. Some men for a very considerable time are unfortunate.

9199. Then they have very little to live on during that time?—Yes; I have known them for 12 months not to have more than 30*s.* a month.

9200. (*Mr. Holland.*) How do they get on?—They get in debt, and, of course, live very hardly.

9201. Do they get food enough?—I should doubt it very much.

9202. (*Chairman.*) Then one third of the men on the average are perhaps not really well fed?—That is my opinion.

9203. (*Mr. Holland.*) Have the men often to go to the public-house to get their money changed?—Once a month on pay days.

9204. Is not that a serious evil?—It is a serious evil, but it is an evil which it is difficult to obviate; it might be done, of course, but there is a difficulty in getting gold enough from the bank. You would have to pay a premium for it.

9205. The miners now have to pay a premium for it?—Yes.

9206. Would it not be a less premium for the adventurers to pay?—The principal reason, I think, is that it saves the mine clerk trouble in counting the money out. A good many of the mine clerks prefer paying a lot at once. Until lately all the women were paid in lumps; perhaps a dozen were put on one bill and they were paid in gold coin and notes; as many were put in a bill as would make a 5*l.* note, and these girls all had to go to the public house. In all the mines that I am connected with we pay them separately.

9207. (*Mr. Davey.*) And that is general now?—Yes.

9208. (*Mr. Holland.*) The other system is broken up?—Yes.

9209. And with benefit?—Yes.

9210. With marked benefit?—Yes.

9211. Would not the same system be beneficial for the men?—It is very much improved, for instance, with the surface men.

9212. (*Mr. Davey.*) What proportion in notes do you pay here?—About half.

9213. Is not that more than usual?—It is.

9214. (*Chairman.*) Should you be ready to pay tutwork-men once a fortnight?—I should not hesitate about it at all; I think that it might be brought about. I think that it would be better if the surface men and women especially were paid once a fortnight.

9215. (*Mr. Davey.*) Do you think that it would be possible to pay the tutwork-men once a fortnight?—Not to measure up.

9216. Do you allow any subsist money to the tutwork men?—No.

9217. In some mines the tutwork-men get 1*l.* subsist at the beginning of every month?—That is equivalent to a fortnightly payment.

9218. Say that this is the 1st of August, those people who worked in certain mines in July received last Saturday 1*l.* each, and on the third Saturday they are paid off?—You pay them for July in August.

9219. The whole of the work done in July will be paid off in the third week in August?—Yes, that is three weeks behind.

9220. (*Chairman.*) The case as stated in St. Agnes where a man is paid all off is not the case here; there is still a month's work due to him in this district?—The pay days in the mine that I am connected with in St. Agnes happen to be nearer to the month of the labour doing; it is rather accidental, I think, than otherwise; there is always a month in hand.

9221. Do you think that the plan of paying up in full at the end of three weeks would be desirable?—Yes.

9222. You would be glad to see it carried out?—Yes, and I should be glad to exert myself to introduce it.

The witness withdrew.

Captain JOHN DAW examined.

9223. (*Chairman.*) What mines have you charge of?—Carn Brea and Great South Tolgus.

9224. In Carn Brea what is the deepest of the levels which you are now working at?—208 fathoms below the adit.

9225. And in Great South Tolgus what is it?—We are sinking below the 140 fathoms from the surface.

9226. Are there any means there for the men to come up and down, besides ladders?—We have a man-engine in Carn Brea for the men from the 105 fathoms below the adit. We now take them from the 105 fathoms below the adit, which is about 137 fathoms, and in 15 or 18 months I suppose we shall take them from the 154 fathoms.

9227. By increasing the length of the man-engine?—Yes.

9228. In Great South Tolgus have you any man-engine?—In Great South Tolgus we have no means but the ladders.

9229. Do you find any difference in working those two mines, the one with the man-engine and the other with the ladders?—Yes.

9230. In what way?—With the man-engine the men are obliged to stay down there for a number of hours; they are lowered by the engine down to the 105 fathoms, and then the engine does not go to work until about ten minutes or a quarter of an hour before their time is up, and therefore we have the advantage of the men's labour.

9231. (*Mr. Holland.*) How much more have you?—I think that we have about 15 per cent. more.

9232. (*Chairman.*) Do the men prefer waiting for the man-engine to attempting to climb the ladders?—They do. They would rather stay down two hours than they would climb up from the bottom of the mine. Last week some of the men were very much put out because we did not work the engine on the Saturday afternoon for them to come up. However, we did not know that they were down, if we had known we should have worked the engine. They complained of not having the engine to take them up.

9233. Do you think that you are able to have older men working in consequence of a man-engine?—Yes. We can send down a man who is able to work, and he will labour as well as if he had only been 20 fathoms below the surface.

9234. You therefore get more experienced men?—We do. That is the way in which we think that we have 15 per cent. more labour; in fact, for the first two months after we put the engine to work we found that we broke about that quantity of stuff more.

9235. (*Mr. Holland.*) That is upon the whole working of the mine?—Yes, upon the average.

9236. (*Chairman.*) Do you use a skip or a kibble to haul?—We use a skip nearly all through the mine.

9237. You think that that is more advantageous than a kibble?—Yes.

9238. It is more profitable?—Yes, we can work cheaper, we can work and draw with wire rope.

9239. You find the wire rope answer?—We find the wire rope answer much better than a chain, but we must have power, we give out two strokes of the engine to make one revolution.

9240. We have been told that the wire rope suffers by the action of the copper water and other minerals; have you any means of preserving it?—We do not work the wire rope down upon the angle of the lode. We work the wire rope over the horizontal pulleys;

then we have 100 or 120 fathoms of chain to the bottom end of the rope. We find that that iron does not crystallize the same as it does when it is winding over the cage.

9241. What is your reason for not working the wire rope further on?—The shafts then go away on the course of the lode, and the angle is not regular. We know that the wire will not bear the friction that the chain will.

9242. (*Mr. Holland.*) It is the underlie at the bottom?—Yes. We have about 100 fathoms from the shaft, and then we have a long piece from the cage to the shaft, and that goes down to the underlie.

9243. (*Chairman.*) I suppose that with power and guide pulleys it might be managed?—Yes, where the underlie is regular and well attended to. At Great South Tolgus we work the wire rope some 30 fathoms from the underlie, and shall go deeper; but then we add to that by putting proper guides and pulleys. At Great South Tolgus we have 14 feet diameter of the cage, and at Carn Brea 12 feet 6 inches.

9244. Do the men ever try to come up in the skip?—No, it is too fast; the engine makes about 7 fathoms at one stroke of the engine, and it is too fast, they do not like it; that is a very powerful engine.

9245. From your experience of the skip and the wire rope do you think that it might be made to answer for men going up and down?—I do think it might be, but there is a very great dislike among the miners in this country to be lowered by means of the kibble or bucket.

9246. But you yourself think that it might be done?—I do.

9247. You would not object yourself?—I should not object myself, and I should recommend it; but if anything should go amiss I might be tried for manslaughter or something of the kind.

9248. You are satisfied that the working of the skip is cheaper for drawing than the kibble?—I can only say one thing, we have been working in Great South Tolgus six years to the latter part of this summer, and we have only had five skip buckets made there, and we have four of them now in the mine. They have been very much repaired, in that time we have worn out one wire rope, and I suppose that the quantity which we draw is about 1,200 tons a month.

9249. Do you know what was the cost of the wire rope for the Great South Tolgus mine?—Yes, it cost us 68*l.*, and 250 fathoms of 4½-inch wire rope at Carn Brea cost us 60*l.*, or within 1*l.* of it; the price was 38*l.* a ton.

9250. At Carn Brea how long did the wire rope last?—We have been working the wire rope there about 12 months, and I do not know how much longer it will last.

9251. There is no effect from corrosion?—No; we well grease it, we rub it in well with the anti-friction grease, and we work there 12-feet sheaves over the shaft, and at Great South Tolgus there is a 14-feet sheave, so that the wire rope will not bear to turn quickly upon a sharp angle.

9252. How many kibbles do you think it would take in the same time?—I should not like to work it with kibbles, because one going up and the other down they are very apt to turn round and injure the rope, and very likely destroy it, but when working in guides they cannot do that.

9253. What is the greatest depth you are working now in either of those mines?—The deepest level that we are drawing from is 197 fathoms. The deepest point of our working is 208 fathoms, but we have not a kibble or skip there.

9254. Where the men are working are there any close ends now?—We have no close ends but what are woll ventilated; we have a direct current of air through them.

9255. How are they ventilated?—We have a waterfall; a height of water falling into a pipe, and that throws in a very good stream of air, and we shall do away with that in the course of a month or two. We shall communicate from one to the other, and shall have one ventilation all through.

9256. You consider that when once you have sunk a winze the ventilation is good?—We have then plenty of ventilation.

9257. How far would you drive beyond a winze?—We do not think of driving more than 25 to 30 fathoms where we are on the course of the lode, then we ought to sink winzes both for ventilation and for the advantage of working and to see what discoveries can be made.

9258. When you are driving at 30 fathoms is not the air sometimes close?—Sometimes; it depends a good deal upon the size that you carry your level; if you carry it a good size there is more room for the air to play.

9259. Do you ever put in air sollers?—Yes, or we put down a stream of water by zinc pipes.

9260. Does it ever happen to you that the candles will not burn?—We never like to put a man where the candles will not burn.

9261. Does it never happen that the air is so close that the candle will not burn?—It may sometimes, it will depend a good deal upon which way the wind is blowing; we do not allow men to work unless there is air for them to work in.

9262. Still the ventilation somewhat depends upon the way that the wind is?—Yes. I was in a mine last week where they had very good air except when the wind was blowing from the south.

9263. What mine was it?—Wheal Uny; there they had not the air so well last week as they had it before; that was owing to the wind.

9264. In what district is that?—It is very near Redruth Church; it is in Redruth parish; but we have no difficulty in the men working if we do not go more than 30 fathoms from winze to winze; there is plenty of air.

9265. Does the current of air come down the winze to that end?—Not always, sometimes it will go up.

9266. When it goes up what is the effect at the far end of the level?—We do not find much difference. We would rather that it should go up because it follows the driving; sometimes it goes up and sometimes down, and why it does so I do not know. You get two shafts without much difference in height, and you have one upcast and the other downcast. Sometimes you find the air going down the shaft this week or this month and up the next.

9267. Does not that affect the current of air below?—No, I do not know that it does; we have no difficulty if we do not go beyond 30 fathoms.

9268. Supposing that you drive a level in which there are several winzes and that you go 20 fathoms beyond, does the air from that level not go up the last winze instead of going to the end of the level?—It will depend upon the state of the level above.

9269. Of course the extreme end of the level is rather deficient if the air goes up a winze 20 fathoms from it?—Yes.

9270. Do you think that they generally attend to stopping the winzes properly so as to drive the air on?—Yes; the men soon find it out.

9271. Is it generally attended to?—The men will attend to those things themselves for their own advantage.

9272. Have they wooden doors given to them?—Yes, anything of that sort they are always provided with, because if they have not air we cannot get a sufficient amount of labour done.

9273. Do you not think that the men very often will, in order to save a little trouble, work on longer than they ought in poor air?—I do not think that our miners will do so.

9274. What means have you of ascertaining when the air is poor?—Only by the candles; that will soon tell us.

9275. Therefore you consider that if a candle will burn the air is sure to be good?—Yes.

9276. With respect to the boilers, have you ever had an explosion?—Yes, in several mines. We had

an explosion of a boiler in Great South Tolgus and also an explosion of a boiler in Huel Uny, and we have had two or three at Carn Brea. All the explosions that have come under my notice have been a regular collapse of the tube from one end of the boiler to the other.

9277. What do you think is the cause of that?—I do not know; it is generally thought that the water is below the back of the tube, but I have never seen anything like it before these last few years.

9278. Does this happen immediately on starting the engine?—No. We had an explosion at Great South Tolgus. I do not know whether the boiler was 5*l.* worse for wear than it was when it was brought out of the factory; it was a strong good boiler, and the plates were as good as when they were put in; and the boiler at Huel Uny was not in more than five or six weeks; it was not a new boiler, but it was thoroughly repaired, and it exploded. At Carn Brea we had one which exploded in about 12 months I think. The tube goes down as close as it can go; there is a collapse from one end of the boiler to the other.

9279. (*Mr. Holland.*) The internal tube?—Yes.

9280. Had the boiler been short of water?—I do not know that it had. There was something in Carn Brea last year; it happened at the time when the directors came on the mine; there were four boilers side by side, there were two on one side and one on the other of the one which exploded. I was standing off, and there were lots of people about; they wanted to know what the cause was. I actually looked up and saw that the steam was blowing away from the pipe—it went through the roof. I said to the engineman, "Go and turn the gauge cock of the "boilers;" he did so, and I found that the first boiler was flush. I followed him up with the others, and he turned the gauge cocks of the three boilers, and they were all flush of water, and in 20 minutes after the boiler exploded we were working the engine again. I never experienced anything like it before because there were three boilers which were flush to the top-cock, and this boiler had exploded.

9281. (*Chairman.*) Were they connected with each other?—They were all connected one with another.

9282. (*Mr. Davey.*) What you have described took place after the explosion?—Yes, the safety valve was above and the weight of steam pressed it down. The engineman was frightened.

9283. (*Mr. Holland.*) Was the internal flue for this boiler large?—The same size as the other.

9284. What was the diameter of it?—I suppose about 3 feet 6; about 3 feet and 3 feet 6 is the usual size.

9285. What pressure was it working with?—About 35 lbs. to the inch.

9286. Was it an old boiler?—No, it was a boiler which had been repaired; it was a good boiler.

9287. Had it been repaired in the internal tube?—Yes, it had been in thorough repair, but it was not a new boiler.

9288. How long had it been working since its repairs?—I had the whole of them repaired it might have been working 12 months; not more than that.

9289. Was the internal tube 3 feet 6?—Yes; the outer tube is about 6 feet and the inner tube is from 3 feet to 3 feet 6—sometimes it is 3 feet and sometimes 3 feet 4.

9290. The tubes are stayed at the side, are they not?—No. Some are made so, but not often; they are not stayed either from the back of the outside case or the bottom; sometimes they have pieces of iron which come down from the outside and take them up, but that is not common, but now there is a piece of T iron which goes round.

9291. Had this boiler that?—No. If the boiler should be 36 feet long I have been in the habit of putting 4 of those.

9292. So as to divide them into lengths of about 7 feet each?—Yes. If we have not T iron we got stiff angle iron.

9293. About what number of men have their wages saved 15 per cent.?—About 370.

9293*a*. About how much can 370 men earn; as much as 40*l.* year each on an average?—Yes, or more.

9294. If so, 370 would earn 2,220*l.* a year or more. Would not 15 per cent. of that pay the cost of the man-engine in 14 or 15 months?—We were breaking a large quantity of tin stuff, and after we had the engine we had so much more, that is, the way in which I estimated it. The man-engine and everything complete cost us 2,400*l.*, but then that includes a new engine and everything.

9295. That would pay in about 18 months?—Yes, it would pay well for every deep mine.

9296. Have you thought about skips for lifting miners?—Yes, and I thought about it before I recommended the man-engine; but our miners in the county have a very great dislike to be lowered in the buckets.

9297. (*Mr. Davey.*) You say that you approve of skips as deep as you work them, in preference to ladders?—Yes.

9298. Supposing that your mine were 100 fathoms deeper, what would be your notion as to using a kibble instead of a skip for drawing stuff?—If I was going 300 fathoms deeper I would have skips.

9299. Are you aware of any mine in your neighbourhood where they use the kibble?—They do in Dolcoath.

9300. But you do not consider that that is the most profitable way of drawing the stuff?—I am quite certain that it is not. I am prepared to test it at any time.

The witness withdrew.

Captain WILLIAM TEAGUE examined.

9301. (*Chairman.*) What is the name of the mine of which you are in charge?—Tincroft.

9302. Any other?—No.

9303. I believe that you have sent in to the secretary a list of the ages and the names of the men in your employment?—No, I have never been applied to for them.

9304. Will you send in a return of the ages and number of men employed underground?—I have not the least objection to do that.

9305. (*Mr. Holland.*) About what number of men are there underground?—From 200 to 240.

9306. (*Chairman.*) What is the depth of your deepest shaft?—From the adit 190 fathoms.

9307. What levels are you working at now principally?—From the 190 up to the 140 principally.

9308. How far from a shaft are you driving a level?—The furthest level is about 100 fathoms, I suppose.

9309. And how far from any winze?—About 30 fathoms.

9310. What is the extreme length which you would recommend driving from any winze?—About 30 fathoms.

9311. You would not go beyond?—It would vary; circumstances sometimes would oblige us to alter that; but generally speaking, 30 fathoms.

9312. But circumstances would oblige you to go beyond a fixed distance from a winze?—There may be shoots of ore that we want to sink in; then we should vary the distance.

9313. Is the air perfectly good at the 30 fathoms?—We find it so.

9314. How do you judge?—We judge from the clearness of the level, and the freeness with which the men can work.

9315. Do you judge at all from the burning of the candles?—Yes.

9316. How long is the powder smoke clearing away from the level?—It may be about a quarter of an hour at that distance.

CAMBORNE.

Capt. W. Teague.

5 August 1862.

9317. (*Mr. Holland.*) Never longer?—No, I should say, not with us.

9318. (*Chairman.*) Is it then quite clear away?—Yes; generally speaking, a quarter of an hour clears it away at that distance.

9319. Have you ever had any close ends in your mine where the air has been poor?—Yes.

9320. How long have the men been obliged to work in that air when that has been the case?—We have set them to work an eight hours' course, but then they have not been compelled to continue the whole of that time there.

9321. They are obliged to leave before the eight hours' course is out when it is close?—Yes.

9322. How long should you think a man could work where the air is close and a candle will not burn?—We do not wish them to work at all where they cannot burn a candle.

9323. But they do work occasionally so in some mines?—We have never seen it; it has never come under my observation.

9324. What means do you adopt for supplying air when that is the case?—Either by air machines, or water falls, or air sollers.

9325. Have you any of them now in your mine?—Not any.

9326. You do not require it?—We do not require it.

9327. The ventilation is complete without it?—We consider it to be such.

9328. But your only way of judging is by the candle burning?—We can easily detect it if there is poor air or damp there; the men cannot work so freely.

9329. By their own feelings they complain about it?—Yes.

9330. Have you ever any cold damp?—No, not at present.

9331. Have you seen it?—I have.

9332. Have you any idea what that arise from?—We generally imagine that it arises from the damp of the granite, the stone in which we are working.

9333. When that is the case the candle burns very strongly, does it not?—No, not very strongly; it flitters; it does not burn strongly.

9334. How do you know when it is a cold damp; what is the sort of effect which you perceive?—It is close, and you feel heavy; you cannot work freely; you cannot breathe freely as you can where the cold damp does not occur.

9335. The cold damp is different from what you call poor air, is it not?—Very different.

9336. How can you discover the differe ge between the cold damp and poor air?—Where there is poor air the candle will not burn at all unless it is put in a different position. But we detect cold damp from the feelings; there is a curious feeling which comes over us, and we can almost see it about the level.

9337. You see a vapour?—Yes, a sort of a mist.

9338. Does the cold damp affect the wood in the mine; is there any white appearance?—I think not.

9339–40. Does the cold damp appear to be at the lower part of the level or does it fill the whole of the level?—Generally speaking we find that it is at the lower part of the level unless there is a stream of water; water may have a tendency to break it a little if there is a stream of water flowing through the bottom of the level.

9341. And that would make it ascend?—Yes, a little, I think.

9342. Do you find this cold damp when the men have not been working or while they are working?—We can detect it more after they have ceased working and when you go into the place again, but we find that the men feel very much from cold damp even at the time when they are working.

9343. How does it affect them?—It affects their breath; they cannot work freely.

9344. Does it affect their stomach?—I think that it has a tendency to affect them in the stomach.

9345. Do they use any remedy when so affected after working in the cold damp?—I do not know that we have ever had any cases; if a man is ill he goes for the doctor.

9346. Do you use any remedy to get rid of the damp?—We use the same means to get rid of the damp as we should to get rid of the poor air.

9347. (*Mr. Holland.*) Is the damp most usual in dry or in wet mines?—In my experience it never occurs but in the granite mines; the granite has a tendency to create a damp.

9348. (*Chairman.*) You have no other means to adopt for getting rid of that except what you use for getting rid of poor air?—That is all that I have ever seen or all that we have ever applied.

9349. How many underground captains have you?—Two besides myself; there are three of us.

9350. Have you any man especially to inspect all the machinery and all the ladders?—The captains and the timber men take charge of that.

9351. There is no foreman of timber men?—No.

9352. Do the men ascend and descend by ladders?—Yes.

9353. Have you ever thought of putting in a man-engine?—Yes, we have thought of it several times.

9354. Do you think that it would be desirable to have some such means for the men to ascend and descend?—Yes, very desirable.

9355. Do you think that it would answer for the adventurers?—Yes.

9356. That the men would do more work?—Yes.

9357. Do you think that you would get any older or more experienced men by it?—We might; but I do not know that there would be much advantage in it.

9358. For drawing do you use skips or kibbles?—Kibbles.

9359. Do you think that is the best mode of drawing?—I really cannot say.

9360. You have never tried the skip?—We have not.

9361. Is there any reason why you have never tried it?—There are several reasons why we have never tried it. I suppose the greatest is, that we have never been in a position to put down a skip, and the cost would be more than we could think of, and the delay in time; it would take months to put in a skip road in many of our shafts.

9362. And it would stop the mine paying?—Yes, for a certain time.

9363. So that even although it was ultimately to be a great saving and advantage you could not undertake it because it would stop the working of the mine?—I do not know; if it was clearly shown to me that it would be ultimately a great saving and advantage I might be induced to recommend it to the adventurers. I would recommend it to them if I was fully satisfied upon the point.

9364. Have you ever been down in a skip yourself?—I do not recollect that I ever have. I think that I did ride once in a skip, that is some years since.

9365. Have you ever had the cost of putting up a man-engine estimated?—We have thought it over; we thought that it would be from 1,500*l.* to 2,000*l.*

9366. Have you ever had under consideration putting a skip for the men?—We have thought of putting a skip to draw the men.

9367. Did you ever ascertain what would be the cost of that?—No; but the cost of a skip to draw the men would be nothing more than just an additional skip, to which might be attached a safety spring for the purpose of drawing the men. If we put in a skip road we may just as well draw the men over it as the stuff.

9368. Are the men limited as to the quantity of candles?—Yes, generally speaking.

9369. To 2 lbs.?—To 2 lbs. a week per head.

9370. What is the charge in the bill for the candles?—8*d.* I think.

9371. What is the charge for powder?—I think we charge them 8*d.* for powder.

9372. What is your rule as to club money, is it for visible accidents?—Yes.

9373. What is the amount of club money that the men pay ?—6*d.* a head per month.

9374. Is there a separate account kept of the club money ?—No.

9375. I suppose that any balance of the club money in case the mine was wound up, would be considered as belonging to the adventurers ?—Yes.

9376. (*Mr. Holland.*) Do the payment by the men and the payment to the men about balance ?—No, the men are in debt very much.

9377. (*Chairman.*) Then you do keep an account ?—Yes, we cannot rup it out without keeping an account, but there is no separate account. If we have five men on the club, those five men are charged as an engine would be charged ; we pay Tom, Dick, or Harry so much a month, whatever claim they have upon the club. There is no club account kept, but we can look at the books at any time, because our doctor's account is exactly the same as the club account ; they are in equal sums. The doctors are paid their pence, and the club is so much, but it is not carried to account ; it is made the adventurers' account.

9378. (*Mr. Holland.*) And you generally pay more than you receive ?—Yes.

9379. (*Chairman.*) Have you had many accidents in your mine ?—Latterly we have not.

9380. But you have a good many pensioners by reason of accident ?—Yes, several. We were rather unfortunate about two years since ; three or four holes exploded, and it threw some men on the club.

9381. Do you take any particular precautions more than other mines with regard to firing ; do you use cartridges ?—No, we have had them, but the men will not take them.

9382. What do the men use for filling in the powder ?—Iron ; that is not used for filling in the powder, but it is used for filling in the tamping on the powder.

9383. (*Mr. Holland.*) Do you put in the powder with a scoop ?—With a scoop or the top of the powder can.

9384. (*Chairman.*) Can you ascertain at all how those accidents happened ?—No. The last two that have come under my notice have been with the third laying of the tamping.

9385. It has gone off then ?—Yes.

9386. And you cannot account for it ?—I cannot account for it.

9387. Do you think that it could have cut the fuse ?—I cannot say at all ; it may have been that or may not.

9388. Might it have been from powder lying about if the hole was not properly swabbed out ?—It may have been ; it is a very rare occurrence that it all exploded with the third laying of tamping.

9389. Have you had any boiler explosions ?—No.

9390. Is your water pretty good ?—No, it is bad water generally speaking.

9391. How often do you examine your boilers ?—Every month.

9392. Is that a regular thing ?—Yes.

9393. Are the boilers then cleaned out ?—Yes, they are cleaned out every month.

9394. Is there a regular record kept that they have been cleaned out ?—No ; the engineer of the mine goes into the boilers every month to see how they stand, or we expect him to do so.

9395. How does the water act on the boiler, does it corrode the plates evenly over ?—No ; we generally find that it gets between the space left over the water, and just on the rim of the water.

9396. Have you any means besides the stop-cocks for the men ascertaining the quantity of water ?—No.

9397. Have you more than one safety valve ?—We have only one on some boilers, but we are adopting two on most of the boilers.

9398. Do you adopt any plan to prevent the man loading the safety valve ?—No.

9399. With respect to the men's deductions, are they charged for the barber ?—Yes.

9400. How much ?—Twopence.

9401. The charge for the doctor is 6*d.* ?—Yes.

9402. (*Mr. Holland.*) Are the boilers ever tested for strength ?—No.

9403. You never try their strength again ?—No, we never try their strength after they are put in.

9404. (*Chairman.*) Do your men change in the boiler house ?—No.

9405. You have dries and changing houses for them ?—Yes.

9406. Do the women work under cover ?—Most of them work under cover.

9407. Have they any place for getting their meals in ?—Yes.

9408. (*Mr. Davey.*) You have not any prejudice against the skip, if you had the means, if you could spare a shaft and could afford the money you would have one ?—It is more than probable that we should. I have no prejudice against them, although I must confess that I do not think there is the advantage in them that people run away with ; but I believe that we should try one if we had a shaft which was prepared to receive one.

9409. (*Chairman.*) How are the doctors appointed ?—They are appointed principally from the adventurers, I believe, generally speaking.

9410. Do not they very often become shareholders ?—They sometimes become shareholders, and then I suppose they think they have a claim.

9411. Are the men consulted at all with regard to the doctor ?—Very rarely.

9412. And you think that that is a cause of dissatisfaction with them ?—I think so.

9413. That they are obliged to pay to a doctor whom they may not wish to employ ?—In some instances they do.

9414. How many doctors have you to your mine ?—Three.

9415. Cannot the men choose which doctor they shall go to ?—No, the doctors generally divide their work according to the districts.

9416. The doctors divide among themselves the districts which they attend ?—Yes.

9417 Do they often appoint assistants ?—Most of them have assistants.

9418. (*Mr. Holland.*) Do they turn the mine work over to the assistant ?—They do not profess to do that I believe ; ours do not, and I believe that most of them do not, but the assistants are called in to help them. I suppose that the doctors like to find them work when they have got them and have the paying of them.

9419. (*Chairman.*) Is there any inquiry into the qualification of a doctor before he is appointed ?—That is what I cannot enter into. I do not know what arrangement they make, I only know that I see assistants.

9420. The assistants are not always qualified persons ?—I do not say that.

9421. Is there any security for their being qualified persons ?—I have never seen any security given for their being qualified persons ; we imagine that the doctors themselves make every inquiry to get the best assistants.

9422. But the men are not satisfied with the assistants ?—At times they are not. What I should like to see introduced would be that if there are three or four doctors about a district they should be named to the men, and that the men when they come into the mine should make choice to whom they should pay the money.

9423. (*Mr. Davey.*) Would there not be some difficulty about that in men changing frequently ?—There may be difficulty, but I do not see why it should not be overcome. There are three doctors in the mine ; the men might be asked, "Which will you pay your money to ?" "I shall pay my money to A, he has attended me for some years and he has done justice, and I shall be pleased ;" and I believe that being pleased is half the cure, if a man is satisfied with the medical man.

9424. (*Mr. Holland.*) Supposing that it should cost

CAMBORNE.
Capt. W. Teague.
5 August 1862.

a little more for giving more trouble to the doctors, do you think that the men would be willing to pay a little more ?—That would be their business; perhaps they would.

The witness withdrew.

Adjourned to to-morrow at half-past 10 o'clock.

Wednesday, 6th August 1862.

PRESENT :

The Right Hon. LORD KINNAIRD, K.T.	JOHN ST. AUBYN, Esq., M.P.
RICHARD DAVEY, Esq., M.P.	P. H. HOLLAND, Esq.
NICHOLAS KENDALL, Esq., M.P.	

The Right Honourable Lord KINNAIRD, K.T., in the Chair.

Mr. JOHN RICHARDS examined.

Mr. J. Richards.
6 August 1862.

9425. (*Chairman.*) What mine have you charge of?—Wheal Clifford Amalgamated mines, in the parish of Gwennap.

9426. Have you the charge of any other mines but those ?—I look after a little mine called Pennance; but that has nothing but a shaft going down; that is also in Gwennap.

9427. Have you sent in a return of the number of men who are employed under you?—Yes.

9428. What is about the number of men who are employed underground?—Somewhere about 600.

9429. What is the number altogether employed on the surface?—I think there are 200 men who are employed on the surface.

9430. Including the women and children?—Including women and children, I think, we have there about 500.

9431. (*Mr. Holland.*) Making together 1,300?—Altogether about that number.

9432. (*Chairman.*) How young do the youngest children come to work?—About the age of 10.

9433. Do they work underground?—No, at the surface; some are under that, but in general we do not like to take them much before the age of 10; some are as young as 7, a few.

9434. I suppose the parents are obliged from necessity to send them so early to work?—Yes; they cannot provide for them otherwise; their gettings are not enough to keep a large family.

9435. To work underground, what is the youngest age at which you admit the children?—13; there may be a few under that age; but they are not allowed to do it.

9436. In what manner do the men ascend and descend the shaft?—By a man-engine; sometimes they go down by ladders; but they can always come up where the man-engine is; that is as far as the Clifford United mines are concerned; but at the Consols we have a shaft 120 fathoms deep, and they go down and come up there by ladders.

9437. What is the depth there?—The depth of the ladder is 120 fathoms, and 40, making 160 fathoms from the surface. The Old Consols is 274 fathoms under the adit.

9438. But you are not working there?—No; the water is let in, and we are keeping the water under at the 120 by one engine; we used to have five or six engines there.

9439. How long has the man-engine been working?—I should think from 18 to 20 years.

9440. Is it a double engine?—Yes. It has been working 18 years.

9441. Do the men come up at all in the skip?—Sometimes they will come up in the skip fast enough if the man-engine is idle.

9442. Do you think they prefer the skip to the man-engine?—No; the contrary.

9443. Could you work the mine without the man-engine?—Not at the bottom; the heat is so much; we could not work at the bottom without the man-engine or a skip; we must have one or the other.

9444. Because the heat is so great?—Yes; and that does weaken the miners; they cannot work a core as they could, or climb up; they would have the hardest work to go through at the latter part of the time.

9445. You mean that they would become so exhausted by the heat that they could not climb up the ladders?—I think they could not; they would not be able to do it.

9446. Would the mine be working now if there was no man-engine or a skip?—I do not think she would be working at the bottom; they might work the shallow parts; but I do not think we could pretend to work the bottom.

9447. What is the deepest level at which you are working now?—230 fathoms below the adit, and that is 40 or 45 I think; that is at the United mines; at Clifford the deepest level is 200 fathoms, and that 200 is very near as deep as the 220 in the United Mines, on account of the loss of level.

9448. What is the heat at Wheal Clifford?—The heat is 102° at eight fathoms and a half under the 200.

9449. What is it at the 220?—About the same; it may be 2° more perhaps.

9450. What is it at the 230?—Hotter, a pretty deal. I should think that you might call the heat there 120°.

9451. When did you last ascertain the heat there?—It was taken within the last four weeks I should say; we carry a thermometer down occasionally.

9452. Is the heat in the mine reported to you?—Yes.

9453. Are the miners working at the 230 fathoms?—Yes; we are driving two levels there.

9454. Does the heat vary much at the same level?—Not where it is a close end; where it is any way from the shaft the heat is just the same; we work at the 230 from three shafts. The men are working regularly from Taylor's shaft and from Garland's shaft.

9455. Does the heat vary when the men are working?—Perhaps the heat is a little more; a very trifle; not much.

9456. In what manner is the air carried into those close ends?—By what we call winzes; we communicate there at every 12 fathoms; we put down a shaft and throw every particle of fresh air that we can down into the level, so that it may ascend up.

9457. Have you no means of forcing it into the end of level?—Yes; we have; we put in air sollers where we a have a draught outwards, and keep it up from the bottom as high as this table, and the air rushes in.

9458. Have you got that now in the 120 fathom level, or in the 230 level?—No; we do not want it there.

9459. What do you mean by not wanting it?—The air is as good as we can make it.

9460. Do you mean that by putting in a soller you would not improve it?—Yes; at present in those levels we have a winze where the air comes down nearly to the end.

9461. How far are you driving now from a winze?—In Garland's shaft about six fathoms; and at Taylor's we are further, I suppose 20 fathoms. Then we are throwing in air there a very large quantity,

taking it up where the draught is uncommonly strong, like the wind through a large pipe.

9462. How many pitches are there in the 220 fathom level?—There are several pitches.

9463. Are they at work?—Yes; I should think that there are working in the back of the 220 fathom and at the back of the 208 fathom levels as many as 60 men in different pairs.

9464. Is the heat experienced by each pair in that level the same?—Yes; in this level the heat is not so much.

9465. Is the heat the same throughout?—Yes, it is exactly the same there.

9466. What is the heat at that place?—The heat there is about 96°.

9467. Are the men who are driving the 220 fathom level exposed to the same heat?—Yes, it is about 102° there.

9468. How long do the men work in a place where the heat is 95° without going back to obtain fresh air?—They work for four hours out of six, or five hours out of six, and they can stand it pretty well; they have been brought up from boys to it.

9469. How long can they work where the heat is 102°?—They cannot stay there I should think without going back an hour.

9470. Do the miners work where the heat is 95° for four hours consecutively?—Yes, very regularly.

9471. Where the heat is 102° you say they can only work for one hour?—Yes, they can only work for one hour before they go back.

9472. How long do they stop where they go?—They stop an hour, I should think, and I suppose that we can get about half the work out of a six hour core,—three hours work.

9473. At the 220 fathom level, how long do they continue at work?—Perhaps in the 220 fathom level we can get just the same as in the stopes, they stay in perhaps an hour and a half, then they go back for half an hour, and then they go in again, and so on; but they are obliged sometimes after the explosion of the powder, and until the smoke is cleared away, to come back.

9474. Suppose they were driving a cross-cut at the 230 fathom level, would there be any difference whether they were driving a cross cut, or driving towards the lode?—Yes, I should think they could stay longer in the cross cut than in the lode.

9475. For what reason?—Because of the fumes of the lode. There is more sulphur in the lode than in the country, the country here is all clean in the branches, the lode is hollow.

9476. When you cut a load, do you find more heat there than in the country itself?—Yes.

9477. And the lode gives out that heat?—Yes, the lode gives out heat more than in the cross cut.

9478. Can the miners work continuously for one hour in the 230 fathom level?—Yes, I think they can if they are used to do it.

9479. Do they do it?—I think so; we do not keep people there always to look after them. They are all upon what we call tutwork; we give them so much a fathom, and they must do their work when the month is out, or else they cannot eat.

9480. Do you never ascertain how long they are able to work?—They are able to work what I tell you I think.

9481. To the best of your belief, do they stay for one hour before they come out to obtain fresh air working in the 230 fathom level?—I think they do.

9482. You have stated that the boys who have been brought up to it can work longer in these hot levels than men who have not been brought up to it?—Yes, I did, they are more inured to it; it is just like where you are working in the furnaces in a great deal of heat with the smiths. A man brought in from the country cannot stand that heat the same as a man who is accustomed to be there, and these boys by being brought up always underground are the men for our hot levels afterwards. We bring them up with the temperature at about 70° or 75°, but the other men will not stay there at all—they stay there only a few cores, and they are off again; and likewise, if you put those who are able to bear the heat up where there is a cold draught, they will not get on so well.

9483. (*Mr. Kendall.*) They cannot bear the change from 70° to 90°, nor from 90° to 70°?—No, not for a month; they will take cold, and get ill.

9484. How are they affected when they become ill?—They are affected in the chest; in the pipes.

9485. They are so affected if they have been working in a hot level and change to a cold one?—Yes, they will get affected in the chest.

9486. Are there any men working in your mine who are thus affected?—There are two or three at the surface, not underground.

9487. Are the miners as much affected by a change from 70° to 95° as those are who change from 95° to 70°?—Yes, just the same.

9488. (*Mr. Holland.*) What effect does the increased heat produce upon them?—They get languid and faint.

9489. And not affected in their lungs?—Yes, they are.

9490. (*Chairman.*) If the miners shift from 70° to 95° they feel faint?—Yes, and languid.

9491. Are they not able to continue at their work?—No, perhaps they may work there for a day or two, and then they will want relief after a while; if they can stand it a month, they will be able to get on.

9492. Do the young miners suffer so much as to be obliged to leave off work altogether during the time of their training?—No; it just depends upon a man's constitution. Some will stay there and not be affected at all. I know many of them who are there that have been there for twenty years and who are not affected to appearance by it, but by and bye if they are taken ill they are gone very soon.

9493. (*Mr. Kendall.*) You say that you have known men who have been able to bear this excessive heat for twenty years, but when they are attacked with illness they are carried off very rapidly?—Yes.

9494. Do you recollect the state of the mine before you holed at Wheal Clifford at the 208-fathom level; when was the hottest time?—About ten years since, before we holed at Wheal Clifford at the 200-fathom level.

9495. Do you recollect what was the greatest degree of heat at that time?—I suppose it was 128°.

9496. How many men had you got working the hole?—We had working in one end, going eastward, 16 men, and we had coming from the other way against that, 12 men.

9497. What was the size of the drift?—The size of the drift was 7 feet high and 4 feet wide.

9498. Had you so many men employed as to have constant reliefs?—Yes.

9499. How many men used to be employed in the same core?—Four in one and three in the other.

9500. What was the mode of working that you pursued?—They would work in this way; the men would go in till they got tired.

9501. How long could they stand it at that time?—An hour, perhaps, was a long time; say half an hour.

9502. Had they plenty of water there to drink?—They always had plenty of water to drink; they had a long way to go back.

9503. Did those men fail much?—I do not think they did.

9504. Do you know anything about their appetites; did they eat well?—Yes; pretty well. The men stood the work like that pretty well; they were not working more than half the time; they were an hour down, or hardly that.

9505. Did you ever know a case of a man being scalded?—Yes; by leaning against the pump.

9506. Is there any chance now of the same degree of heat being found again?—I do not know. The only thing is this, that perhaps there would be at the bottom of the mine. We do not do anything under the 230-fathom level now. We have a shaft under

CAMBORNE.

Mr. J. Richards.

6 August 1862.

that, about 5 or 6 fathoms; but lately we have abandoned it.

9507. Supposing you were obliged to sink in order to get to a deeper level, might not the same thing occur again?—Yes; I think it would.

9508. Have you ever adopted any means to remedy that?—Yes; we have. We brought down a fresh current of air, and threw it back through the bottom of the level, and brought it up, and in places it had the desired effect; but where that place is that I spoke of last we can now bring in a larger current of air than we did, and remedy it in part.

9509. But that is not done now, is it?—No; because we do not work in that very hot place.

9510. Would it not be worth while to do the same thing at the 230-fathom level?—We have a pretty good draught there.

9511. Is it not worth your while to try to reduce the temperature there?—I do not know how to do it.

9512. If you could introduce a stronger current of air would not that reduce the temperature?—Yes; I should think it would.

9513. Is it not the expense of bringing it down that stands in the way?—Yes.

9514. But it would be an advantage to the men, would it not?—Yes; no doubt. If we could get the same draught that we had at Taylor's we should remedy the evil, but it is a long way to bring it.

9515. How much do you think you could reduce the heat?—I should think we could bring it down to 114° or 115°. The remedy is a slight one, because very often the great heat will overcome the cool draught before it is in sometimes.

9516. Are you quite sure that the heat at the 230-fathom level does not exceed 115°?—I should think so.

9517. When was it tested?—I do not know. I do not think that it has been tested for a month, but we will try it next week if you desire to know.

9518. Is the water of the same temperature as the air?—Yes; very nearly. It does not vary more than a degree or two.

9519. How do you account for the great heat there?—My opinion is that there is some ingredient in the lode, whether sulphur or not I do not know.

9520. Is the lode a large lode?—The lode is as large in places as this room is wide.

9521. (*Chairman.*) Are you quite sure that the miners can work for an hour in a temparature of 116°?—I think so. They are ordered to work longer than that; and I think that the men do work that.

9522. How far have the miners to go from the end of the levels at the 230 fathoms and at the 220 fathoms for fresh air?—At the 230 fathom level, I suppose they must go back and climb up above 20 fathoms, and go in from that place to where the level is, and if they go up 20 fathoms they will have very good air.

9523. Then they go from the end after working to get fresh air every half hour, or every hour?—Every hour; but perhaps they do not go where the fresh air is, they go up to one level where the air is better.

9524. Suppose that a man's candle goes out, and he has no matches, or they have got wet, what might happen then?—They have always got matches.

9525. But suppose they had not got any, or that they had got wet, and would not light?—Then they must go to a neighbour; there are people working not far off.

9526. But how would they go along the level, would it be safe to go along the level without a light?—Yes, the light would, of course, be preferable, but repeatedly the miners have to walk a good way in the dark to get a light, but not since the present matches have been in use, they generally carry them with them.

9527. They have not to go on their hands and knees, groping their way along for fear of falling down through the winzes?—No.

9528. Did you ever know a man to find his way from the bottom of a mine to the top in the dark?—Yes, it is from the use of it.

9529. Are all the openings between one level and the other well protected?—Very well.

9530. The timber-men have charge of those matters?—Yes.

9531. Who is it that reports to you as to the state in which the mine is in those respects?—The agents very soon report it. They have to go through those places every day, and if any thing was defective, of course the timber-men are ordered to put it right.

9532. Is it perfectly safe to go along one of those levels without a light?—Certainly, to people who are used to it.

9533. Would they know that there were large gaps or holes running down to other levels?—Yes.

9534. Have you never known an instance of a man being obliged to go on his hands and knees for fear of falling down any of those holes?—Yes, if they have to go across a shaft or something of that kind, they must be very cautious, but where these winzes, or workings are at the bottom of the levels, which they pass every day, they can do that.

9535. In the dark?—Yes; but you will not find so much darkness down there since the lucifer matches have been in use.

9536. Is the air good down below although it is hot?—Yes.

9537. Does not the great heat in the mine cause a areater down-draught, and so bring in a current of gir?—No; if we want a current of air we send it down; but the air down there, the hot draught, is not so injurious as you might suppose.

9538. I understand that accidents are frequent, such as men falling from one level to another; do those accidents ever occur in your mine?—Very seldom; we had one man who fell in a shaft a little while ago.

9539. Was he climbing at the time?—No, and he had a candle alight with him.

9540. How did the accident happen?—He slipped his foot or his hand.

9541. There is no rail to protect any one?—There can be none in the shaft where they are sinking down, if you are sinking a shaft the whole length is only four feet long, and there is a pump going down there; here they had a rope to wind them up, and they must draw the kibble over their head.

9542. But that was while they were working at the shaft?—Yes.

9543. Have many accidents occurred in your mine during the last three years?—Not many.

9544. Can you state how many?—No.

9545. What allowance of candles do you make to the miners?—2 lbs. of candles per week to each man.

9546. Were more candles allowed to them when they were working in that hot end?—When it is very hot they have 2½ lbs.; but they do not burn 2 lbs. down in those hot ends, they only keep one light.

9547. What kind of candles do they use down there?—They are made of the best tallow.

9548. Do you use any patent candles?—Yes, we do, some of them.

9549. What do you charge per pound for the candles?—Sevenpence.

9550. How long is the powder smoke clearing away in the 220 and 230 fathom levels?—I suppose the powder smoke would take half an hour to go off, sometimes more, sometimes an hour, it depends upon how wet the hole is; if it is very wet it will make more smoke.

9551. What do the miners pay you for powder?—They pay eightpence a pound.

9552. What amount do they contribute for club-money?—Each man contributes sixpence per month.

9553. Is that to provide for visible accidents?—Yes, for visible accidents, or if they have been hurt by long continual working in the mine they are paid the club. If a man comes to perhaps fifty years of age, then we pay him the same as we pay to a man that is hurt if we have reason to think that he came by the illness there.

9555. What allowance do you make to them?—25*s.* a month.

9554. Is there any account kept of the club-money separately from other account?—Yes.

9556. Is the club-money that is contributed by the miners sufficient to meet the expenditure?—Yes, but sometimes it is not, sometimes it is more, but I think that our club stands on rather good ground now, there is a balance in hand.

6557. To what amount?—It is not very heavy; perhaps 70*l.* or 80*l.*

9558. Is there any charge made to the miners for the barber?—No.

9559. How are the doctors appointed?—They are appointed by the adventurers.

9560. What is the charge made to the miners for the doctors?—6*d.*; then the doctor must attend them through sickness or hurts; that is, the man himself, not his family.

9561. Are the earnings of the men more in this than in other districts?—No, I should think not; their gettings generally are about 3*l.* or 3*l.* 10*s.*; sometimes we give them as much as they can do in a month; if the ground is favourable they will get more money.

9562. But a miner may get less than that?—Yes; I should think that the average gettings are 3*l.* 10*s.* a month.

9563. Some earn more and some less?—Yes; where they are able men they are pretty regular.

9564. Are there more men who get more than that than those who get less than that?—There are more who get less than that.

9565. With regard to the boilers, does the water that is used injure the boilers?—They are obliged to bring water there; we do not use the bottom water for the boilers at all.

9566. You bring the water to the boilers?—Yes; and we pay a rent for the water; we have an engine to pump that water up from a shallow level in order to send it all round the mine to the different engines; we have large wells there as reservoirs to receive it, and we take it out as we want it.

9567. Have you ever known a boiler burst?—Yes; only yesterday, I am sorry to say.

9568. Was any body killed?—No; nor hurt.

9569. Do you know how that was occasioned?—I do not.

9570. Are the boilers examined regularly, or at any stated periods?—They are examined every month pretty regularly; we cleanse them, and they are examined all through.

9571. Is any record kept of such examination?—No.

9572. Was the engine at work when this accident occurred?—Yes.

9573. Had it been out of work?—Yes; the evening before it occurred they had cleansed this boiler, and they lighted a fire, and the boiler filled at four o'clock, and it worked on till midnight, and they stopped to change the bucket, went to work again, and they thought that they were working all right, and about seven in the morning off went the boiler.

9574. Have you any water-gauge?—We have a cock and a safety valve.

9575. But no water-gauge?—Not up.

9576. Do you test the quantity of water in the boiler by working the taps?—Yes; by working the cocks; we have two, one near about the level of the top of the tube, and another about three or four inches, which we call the working gauge.

9577. Is there more than one safety valve?—No; there is one to each boiler.

9598. You test the quantity of water in a boiler by the cocks?—Yes.

9579. Is there a float to the feed-pipe?—No; we force the water in.

9580. (*Mr. Holland.*) You have stated that there were 60 men working in the 220 fathom level?—Yes.

9581. At a temperature of about 95°?—Yes.

9582. Did they generally work only for four hours out of six?—Yes; about that.

9583. Was not one-third of their time lost thereby?—They worked eight-hour cores.

9584. In consequence of the high temperature they would be only doing three-fourths of the work that they would otherwise be able to do in cooler air?—Yes.

9585. Their net earnings would be something more than 200*l.* a month?—Yes; but you must add the cost to that (4*l.* 10*s.* a month); we must pay 4*l.* 10*s.* a month, and then we should have that returned again.

9586. Of which one quarter, or 50*l.* a month, is lost in consequence of the hot air?—Yes.

9587. Therefore, if you could reduce the temperature of the air, say to 70°, at any cost less than 50*l.* a month you would gain by it?—Yes; but I am sure we could not do it at that cost.

9588. If anybody furnishes you with a plan which enabled you to do it for less than 50*l.* a month, would you not be very much obliged to him?—We would try it.

9589. Do you think, from your experience, that a modification of the skip would supersede the necessity for a man-engine?—Yes; you could put a skip in at a good deal less expense; but then, if anything should occur from the rope breaking, the loss would be more than it would in the case of the man-engine.

9590. What objection have you to the skip, except the chance of the rope breaking?—Because we cannot bring the men up fast enough.

9591. But suppose you brought them up on stages, would it not answer?—Then we must have another machine on purpose for it; it would hinder us two hours a core; that is, two or three times a day; therefore it would hinder us six hours in the 24 in bringing the men up. You cannot go down with the skip more than about once in ten minutes, or six times in an hour, and we should not bring them up in that way.

9592. But with a double skip you would bring up twice as many?—Yes; but six times 4 make 24 men, and twice 24 make 48 in both lifts, and we can bring up in 20 minutes with the other 100 men; the man down at the bottom gets in, and by the time he gets up to grass there are 125 steps; that bottom man will have taken half an hour; but when they are on the rope they will not come up quickly enough.

9593. Have you any other objection to the skip?—None at all, I believe.

9594. You have mentioned two—the chance of the rope breaking and the loss of time?—Yes, in bringing the men up.

9595. The danger of the rope breaking and the skip falling upon the men might be easily guarded against?—Yes.

9596. If those difficulties could be overcome, your objections would be removed?—Yes.

9597. (*Chairman.*) Supposing you had an extra drum with the means of taking down nine or ten at a time, and two skips to be used only for the men, do you think that would answer?—Perhaps it would, but there would be the extra cost, and we do not want it with us.

9598. But do you think it might be made to answer?—Yes, I think that the skip might be made to answer to bring up the men. If there was any good prospect, I should prefer a man-engine; but in a small mine, and with bad prospects, I should prefer a skip.

9599. Has any accident ever occurred with the man-engine?—Yes, once.

9600. How did it occur?—The man missed the steps.

9601. Do you think there is no danger if the iron handles by which they hold on are off?—There ought to be none off.

9602. How could a man hold on without them?—He has to keep his hand on the side of the rod; the iron handles are off but very seldom.

9603. But if they are off, do you think there is no danger in it?—Not with people who are used to it.

CAMBORNE.
Mr. J. Richards.
6 August 1862.

9604. Do you think it is safe to hold on only by the rod ?—Yes.

9605. Do you not think that for the safe working of a mine, it is desirable to have one man employed in inspecting the whole of the work, and to see that every one thing is in good working order ?—To be sure.

9606. Do you employ one man for that purpose ?—We have one inspector there to look after all the machinery in the mine.

9607. And also the foot ways ?—Yes.

9608. (*Mr. Kendall.*) Should you not consider that what was perfect safety for the miner would be rather dangerous for a perfect stranger ?—To be sure.

9609. The Chairman asked you just now about the danger in the different levels in consequence of the winzes not being covered over. You often leave them open, do you not, with a small plank placed across ?—Yes.

9610. If a plank six or eight inches wide were placed over a winze 50 feet deep, you would call that perfectly safe, would you not ? —Yes, I should say so.

9611. You would give a stranger a helping hand ?—Yes, we should be very cautious with them, and show them a light.

9612. If you were to cover over those winzes in order to accommodate a stranger, would not that a good deal interfere with the ventilation ?—Yes, very materially.

2613. Do you think that a miner has to crawl across a plank of that kind, when his candle accidentally goes out, twice a year ?—Not across a winze.

9614. Do you think he crawls anywhere twice a year, if his candle happens to go out ?—Perhaps he does.

9615. Ought a miner ever to be without a light ?—No.

9616. I suppose that for a halfpenny a year spent in lucifer matches, he could get light enough to guard against everything ?—Yes, the miners are not allowed to be without a light ; if they are, it is their own fault.

9617. Have you many men in your mine who have been disabled from working in very hot levels ?—There are four or five.

9618. I suppose you have more men who have become disabled from working in hot levels than from working in the cooler levels ?—Yes, I do not know that we have one there.

9619. Is there any difference in the look of the men who work in the deep levels ?—I do not think there is any great deal of difference in their looks, perhaps the very hot levels make them look a little more flushed in the face, and perhaps that is a bad sign.

9620. What is your opinion as to the general health of the miners ?—I think that the general health of the miners is pretty fair.

9621. Your mine is the hottest mine in the county, is it not ?—Yes, there is nothing like it, I think.

9622. Do you know much of the agricultural population ?—A good deal.

9623. Is there much difference between them and your miners ?—I should say that our miners do not live so long as they do by some years.

9624. How long have you worked underground ?—From the beginning. I have been a miner for 40 years.

9625. How old were you when you began to work ?—About 15.

9626. What is your age now ?—I am bordering on 70.

9627. Do you go underground now ? — Very seldom.

9628. How long have you ceased to go underground ?—I have not ceased at all ; but to go down regularly I have ceased about two years.

9629. Up to the age of 67 then you went underground regularly ?—Yes.

9630. Up to that time were you as strong as other men ?—Yes ; but I have not had as hard work to do as other men.

9631. Did you work your way up ?—Yes.

9632. For how many years did you work as a miner ?—For about three or four years.

9633. Your principal employment since that has been as an agent ?—Yes ; and my father was an agent before me.

9634. You have never had to perform the hard labour of a miner ?—Not for years.

9635. Your father was an agent before you, and I suppose you stepped into his shoes ?—I did afterwards.

9636. (*Mr. St. Aubyn.*) Can you state what is the average cost of a man-engine per fathom ?—3*l.* 10*s.*

9637. What is the average cost of a skip per fathom ?—About 30*s.*

9638. (*Mr. Kendall.*) If you could get rid of the danger connected with the skip, and you could also bring the men more quickly up, you would prefer a skip ?—I will not say that. I prefer a man-engine.

The witness withdrew.

Mr. JOSEPH JEWELL examined.

Mr. J. Jewell.

9639. (*Chairman.*) Of what mine have you charge ?—East Tolgus.

6640. Have you charge of any other mine ?—South Tolgus, West Tolgus, and Tolcarne.

9641. Which is the deepest of those mines ?—South Tolgus.

9642. Have you sent in to the Secretary a return of the number of men in your employ ?—Yes.

9643. How many men altogether are under your charge underground ?—There are 236 men and 56 boys.

9644. What is the number of the other persons who are employed ?—About 120.

9645. What is the deepest level in the mine ?—The 130-fathom level below the adit. A shaft or sumpt is down there for another level, for the 140-fathom level.

9646. Are the miners working at the 130-fathom level ?—Yes.

9647. What means are employed for the men to ascend and descend the mine ?—Ladders.

9648. Does the mine produce copper or tin ?—It produces copper.

9649. How far are any of the levels driven from any shaft ?—About 200 fathoms east and west.

9650. How far from a winze are you now driving ?—Some six or seven fathoms ; some about ten fathoms ; and some 15 or 16 ; after that we generally sink down winzes.

9651. What is the extreme length that you drive an end from a winze ?—About 20 or 23 fathoms is just as far as we go.

9652. Are there any hot or close ends ?—Nothing in particular that I can speak of ; none at all.

9653. Are there any ends in which a candle will not burn ?—None.

9654. Do you not require any artificial means for the purpose of throwing in air ? — Sometimes we throw it in by a waterfall ; the places get a little warm in 18 or 20 fathoms.

9655. Have you got that at work at present ?—We have at Tolcarne at present. We put it to work yesterday. That level is in about 17 fathoms from the shaft.

9656. How close are the pipes taken up to the end of the level ? — About three fathoms behind. We generally keep a false pipe, and when they blast a hole they take out that pipe and put it back again afterwards.

9657. How long is the powder smoke before it clears away where this pipe is ?—Probably ten minutes or a quarter of an hour.

9658. How long would it be if the pipe had not

been put in?—Probably half an hour or more. I should say more than that.

9659. Have any accidents occurred from blasting during the last three years?—One occurred in South Tolgus about two months ago.

9660. Were you able to ascertain the cause of that accident?—I believe it was through carelessness on the part of the man himself.

9661. In what way?—From putting in the tamping on the powder with an iron rod; that is not allowed to be done, nor in any of the other mines. He confessed it afterwards. His sight has been injured for a little while, but he will be able to work again in a few days.

9662. He has not lost his sight?—No.

9663. Do you supply the miners with wooden rods for the purpose of cleaning the hole previous to and after charging it with powder, not for tamping?—Yes; every man in the mines has got one.

9664. I suppose the accident occurred from the iron coming in contact with the gravel and striking a spark?—Yes; there have been instances when the fuze has been cut by the ramming bar, the "iron" as they call it, but not in our mines that I have seen or have known.

9665. What quantity of candles do you allow to each miner per week?—2 lbs. per week.

9666. What price do you charge them for the candles?—About 8*d.* per lb.

9667. Do you vary the price?—Yes; we send out for tenders; we ask the merchants what they will supply us with candles for for two months; and, in fact, they are at this time 5*s.* 3*d.* a dozen pounds, and we let the men have them at 8*d.*; In some of the mines it is 8*d.* We charge a little over in places, but that is just how we gave them out to the men before.

9668. Do you do the same with regard to the powder?—No, we charge them 8d. a pound for that, whatever the price of it is; but the price has been just the same for several years. If it came down to a much lower price, I dare say that we should take it down to 6d.

9669. Do you use any kind of patent candles?—No.

9670. Or any patent powder, or powder of any particular kind?—We have tried all the powders.

9671. Is there any difference as to the smoke that is made after an explosion?—Mr. Davey's powder at the commencement did not make so much smoke. I gave an account of that in a paper. I thought that the men might go in to work again in five minutes in an ordidary place, but I see very little difference now. I remarked it last week underground.

9672. Is the powder not so good as it used to be?—No; it makes smoke just like other people's powder.

9673. It would be an advantage to you, would it not, to have powder that did not make so much smoke?—Yes.

9674. Do you think that the smoke is at all injurious to the miners?—I do not think that it does them any good.

9675. Have you had during the last year any men out of employment, in consequence of having worked underground?—No.

9676. What amount do the men pay as club-money? 1*s.* per month for doctor and club.

9677. Is the club-money applied in cases of visible accidents?—Yes.

9678. Is there a separate account kept of the club money?—Yes.

9679. Are the doctors appointed by the managers or by the adventurers?—By the manager. Mr. Taylor generally takes it upon himself to appoint the doctors. I have been under him for 25 years, and it has ever been so since I have been with him. We appointed the doctors, or he did, a few months ago at West Tolgus.

9680. Does that mode of appointing the doctors give satisfaction to the men?—Sometimes it does, and sometimes it does not.

9681. With regard to the boilers, is the water that is used not injurious to the boilers?—Our water is very good.

9682. How often are the boilers tested and cleansed out?—Once in three or four months.

9683. Is there any regular time for that to be done?—Yes; we generally do it every quarter, or every four months.

9684. Do you make any record of the time when the boilers were last cleaned out?—Not exactly. The working engineer of the mine sees to that, he sees that it is done properly. We keep a working engineer on the mines, and he goes from one mine to the other to see that these things are attended to.

9685. Do you think that when the men are paid in notes they are induced to go to a public house to obtain change?—Certainly, they must go somewhere to get change.

9686. (*Mr. Holland.*) Is there only one doctor employed in this mine?—There are two at South Tolgus.

9687. May the men choose which they will go to?—Yes, which ever they please. There are two doctors in every one of the mines.

9688. And the men have a free choice as to which they will go to?—Yes; there are three doctors at East Tolgus.

9689. Does that prevent discontent?—I do not hear but very little said about it. I put a question to the men about it. Some of them will complain a little at times.

9690. Is it much better to have two doctors than only one, so as to give the men a choice?—Certainly.

9691. (*Mr. Kendall.*) Do you think it would be a good plan if, instead of having doctors specially appointed to take the mines, you had doctors for a district, and if they agreed to attend to any man who might come to them?—I think that that would be a very good plan.

9692. Do you think there would be any difficulty in getting the medical men to fall into such an arrangement as that?—I cannot say. I think it would be a good plan, for then a man might choose his own doctor.

9693. And then the doctor would have the doctor's money, whoever he might be?—Yes.

9694. Is your mine a healthy mine?—It is very good.

9695. Is it well ventilated?—Yes.

9696. Have you many men on the sick club?—There is not one at this time.

9697. Then, I presume your club is rich?—Sometimes we have accidents, but I understood you to speak of men who are laid up through disease from bad air.

9698. Have you no case of a man who is laid up from having breathed bad air?—Not one at this time in our mines.

9699. Have you had many men laid up from that cause?—No.

9700. Is the natural ventilation in your mines good?—Very good indeed.

9701. Have you very seldom to resort to artificial means?—Yes.

9702. (*Mr. St. Aubyn.*) You have no doubt as to the man-engine being a better thing than footways, where it can be conveniently introduced?—I think it is most essential for the well being of mankind. I did belong to the mine where Mr. Richards is, where a man-engine was put up, and I found it very good.

9703. You have a preference for the man-engine, as compared with a skip?—Yes, I prefer a man-engine to a skip myself.

9704. Do you consider that the health of the miners generally in this district is better than it was when you began mining?—I do think so; very much better.

9705. To what do you think that improvement in their health is attributable?—It is because the mines are better ventilated.

9706. Can you suggest any means for improving the ventilation in the mines to a greater extent than

CAMBORNE.

Mr. J. Jewell.

6 August 1862.

it is already improved ?—I do not know that I can; it is generally owing to the shafts being sunk at the proper distances, and to winzes being sunk in the intermediate ground.

9707-08. Speaking generally, do you consider that the mines in this part of Cornwall are ventilated as well as they can be ?—I do think that they are. A great many of them are where I have been down.

The witness withdrew.

Mr. JOHN CADY, CAPTAIN PASCOE } Examined.

Mr. J. Cady. Capt. Pascoe.

9709. (*Chairman to Mr. Cady.*) I believe you have charge of the South Frances mine ?—Yes.

9710. Are you the purser of that mine ?—Yes, and Captain Pascoe is the manager.

9711. You use a skip at that mine, do you not ?—Yes.

9712. How long have you had the skip in operation ?—Since 1857.

9713. Is it employed for taking the men up and down as well as for drawing ?—Yes.

9714. What was the original cost of the skip, the wire rope, and the fitting up of the whole machinery? —In the statement of those particulars which I will now hand in, I have gone rather over than under the mark in the calculation. I am sure of that.

The following paper was handed in:

Notes on drawing Guides, and Skip in use in Marriott's Engine Shaft at South Wheel Frances.

In making the following calculations as to cost of construction, working, &c., 150 fathoms' level from surface is taken as a datum.

Outlay for guides, 150 fathoms at 25*s.*, 187*l.* 10*s.*

	£	s.	d.
Do. wire rope 300 fathoms	50	0	0
Do. skip, springs, &c.	20	0	0
	£70	0	0

	£	s.	d.
These guides would last about 10 years with proper attention in repairs, giving therefore a cost per month	1	11	3
Calculated to stand 3½ years would be per month	1	13	4
Maintenance of way per annum, 5*l.*, would be per month	0	8	4
Wages of engine-man, lander, fillers, and smith, per month	12	10	0
Cost of coal, oil, grease, &c., per month	10	0	0
Patent fee	0	10	0
	£26	12	11

The low estimate of 50 tons of stuff and men drawn per day, at 26 days per month, would give 1,330 tons per month=4·76*d.* per ton.

The guides are 6-inch square rods, hoppers, or filling plats to hold as much as skip, and no more.

9715. Has the new system enabled you to effect a considerable saving ?—Yes, considerable.

9716. Can you furnish the Commission with accurate information as to what the saving is ?—Yes, we can furnish it, I should say, decently fair, or an approximate estimate. The hoppers for filling are the invention of Captain Pascoe, and they are so contrived that they shall hold measure for measure exactly the same as the skip; it was difficult with the old hopper, for when the door fell, that door did not stop the stuff from running into the skip, and Captain Pascoe's idea was that if we had measure for measure, it would be better, as it would then be simply to lift the door, when its contents would fill the skip. During the journey of the skip to the surface and its return the hopper is again filled, so that we can fill with a single skip equally as fast as if we had two skips.

9717. How long is the skip going down and coming up ?—About four minutes or five minutes in the usual way of drawing. We could do it faster if we were driven to it. I have not assumed it to be so fast in the statement I have handed in. I have put down 50 tons a day only.

9718. Could you draw more than 50 tons a day ?—Yes, we could draw 100 tons a day with the greatest ease by simply employing another engine man, and working a little longer cores.

(*Mr. Pascoe.*) We could pull up 100 tons in rather less than 12 hours.

(*Mr. Cady.*) Yes, if we were driven. The pulleys we use are of large diameter. It is a very important matter that the rope should be wound over a proper pulley.

9719. How is the rope wound ?—It is wound round a perpendicular drum, and the pulley over which it goes to the shaft is 14 feet, and the drum is 11 feet in diameter. We could not make it larger.

9720. How do you obviate the objection that has been made with regard to the wire rope corroding ?—That is most easily done; we have simply a box that is filled with grease, and the rope runs over the surface of it, and so the rope is lubricated.

9721. (*Mr. Holland.*) Is there a great consumption of grease ?—No.

9722. (*Chairman.*) Do you know the particulars as to that ?—I have estimated that in the statement I have just handed in.

(*Captain Pascoe.*) There is very little consumption indeed when the rope is got into proper working order.

9723. Do the men make any objection to going up and down by the skip ?

(*Mr. Cady.*) No. They make great objection if they are prevented. It is quite the other way.

9724. No man objects to the skip ?—No, but we hear great complaints if they do not get up and down by it.

9725. Have you a safety catch ?—Yes, Bennett's patent catch.

9726. Can you stop the skip at any level by signal? —Yes, we can. The nature of the engine shaft is perpendicular to the 30 fathom level. From thence we go on an incline of 18 inches in a fathom all the way to the bottom of the mine—we break that angle by pulleys, or shaft rollers, as they are called, and our roller is nicely contrived—the skip may pass as freely as a bird can fly, at the angle; but with reference to the kibble, that shaft being under an underline, it would be necessary to have bed plank from the bottom to the top, three inches thick, and consequently very expensive; the bed plank, all scantled and sawed out of American and Norway deal, in proper lengths, and sometimes they would haul out, then the chain working upon them would be just like a saw, and they would not stand very long; now we have a skip, and we want nothing of that. It is kept out from the rubbing and the wear by the guides, and consequently the saving is very great indeed.

9727. (*Mr. Holland.*) Have you made any estimate of the saving effected in the available time of the miners by the use of the skip ?—The saving effected in the time of the miners is this, that they can come up by the skip in two minutes from the level, and they would have had to climb at least half an hour at that average depth.

9728. To how many men would half an hour be saved ?—80 men a day.

9729. What amount of fatigue or labour do you think the exertion used in climbing up would be equal to—as much as an hour and a half ?—The old men have remarked to me that they would as soon work half a day as climb up that depth.

9730. What would be a fair average to assume, taking the men altogether ?—A quarter of a day.

9731. Do you mean a quarter of a day's fatigue?—Yes.

9732. Would it be fair to assume that the saving in the wages is equal to 25 per cent. as the result of employing a skip?—About 20 per cent.

9733. One fifth?—Yes.

9734. Is not the liability to catch cold diminished by the men being able to come up cooler?—Yes, very much.

9735. Do you think that the frequent catching of cold is one of the causes of the miners' complaint?—I have no doubt that the over-action of the heart by climbing, and their getting into the great heats that that they do very much predispose them to catch cold, but that is quite done away with by coming up in the skip.

9736. I think you stated that it has been in operation for four or five years?—Yes.

9737. Have you observed any diminution of disease among the miners since its introduction?—No, I never did; the fact is, they are constantly shifting.

9738. Can older men work with comfort in your mine than worked there before?—Yes, they can, most decidedly.

9739. (*Mr. Kendall.*) How many men can come up at a time in your mine in the skip?—Five; four can do it easily.

9740. Can they come up in about four minutes?—They come up in two minutes, they descend and ascend in that time.

9741. How many men can you take up and down in a day, so as to keep to their hours?—We can send down four, and bring up four every five minutes.

9742. Is yours a single skip?—Yes; we could not with two skips pretend to put a wire rope to any of the different depths with that rapidity.

9743. Has it a patent safety catch, so that if the rope break the stoppage is instantaneous?—It has.

9744. Would the men be liable to be jerked out from it or not?—No; they could not be jerked out, as the skip is high enough to cover the neck.

9745. There would be a shock, would it be a dangerous one?—Not at all; the shock would be very little, because at the greatest speed it scarcely goes nine miles an hour.

9746. Have you made any experiments with it?—I have seen the rope pulled right out of the socket by the engine-man, when the skip full of stuff caught in the guides, I should think with nearly a ton of ore in it (ascending); we also put on false pieces of hempen rope, to the wire rope and let the wire rope bag, and then we cut the hempen rope in two.

9747. (*Chairman to Capt. Pascoe.*) Have you inspected other mines?—Yes, many.

9748. Do you see any difficulty in the case of an underlie, in applying the skip?—No, I do not, with proper care; we are working a wire rope in another shaft in South Frances, and there we have four or five turns, and that is working very satisfactorily indeed.

9749. Are you of opinion that the skip for the purpose of taking the miners up and down might be applied, generally speaking, throughout all the mines?—I should say so, most decidedly; of course in many mines where they could probably hardly afford to go to the expense of a man-engine. I think they might pull the staff up, and send the men up and down just as we do with perfect safety.

9750. And also with economy?—Yes; considerable economy, I should say.

9751. Have you ever considered whether it would be possible to have two wire ropes and two drums, and put one out of gear, so as to have a carriage for the men to go down in instead of a skip?—Our shafts will not admit of that.

9752. I mean setting one aside at the top, and working the other down the same place?—Yes, I understand that; they send them down in the coal mines, I think, something like that. I do not think we should gain anything by it.

9753. It has been suggested, that there would be a difficulty in sending down a sufficient number of men by a single skip; but if you could send down a carriage containing eight or ten men, as in coal mines, would not that surmount the difficulty?—Yes; but our shafts are not so large, and therefore we could not have a platform large enough.

9754. Could not the men stand one over the other, in tiers?—Yes; it might be done very nicely, I think.

9755. (*Mr. Holland.*) How would you prevent the wear of the rope in dragging along the floor of the shaft where there is a large underlie?—By rollers.

9756. Those rollers would have to be more numerous in proportion as the steepness was less?—Yes.

9757. Are the rollers a serious expense?—No, a mere trifling expense, just a little bit of oak; they make them in a very little time.

9758. (*Mr. Kendall.*) What is the weight of the rope per fathom?—From 10 to 11 lbs.

9759. Did you ever go down a mine by a man-engine?—No.

9760. You are hardly acquainted practically with the merits of a man-engine?—No; but I know that in a skip there is scarcely any presence of mind required by it as compared with a man-engine; you must always have presence of mind to go from step to step.

9761. What are your changing hours?—At two o'clock, at ten o'clock, and at six in the morning.

9762. You expect all the men to be at the surface or down at the 120?—Yes, they can work for half an hour longer by riding than they could by climbing.

9763. Have you any rule as to ascending and descending?—Yes.

9764. How is it done?—The men receive a signal.

9765. I mean as to the order in which the men get into the skip in going down?—The first pair there take their turn, they do not interfere one with the other.

9766. There is no quarrelling about it?—No.

9767. Suppose there were sixty men to come up the last five would have a long time to wait would they not?—We have never so many as sixty at a time.

9768. What is the greatest number that you have at a time?—Thirty or forty men.

9769. Supposing that there are forty men at 2 o'clock, you can only take down five at a time?—They would go down six at a time.

9770. What is generally the number taken down?—Six.

9771. Then the last man would have to wait half an hour?—Yes; but when he goes down he goes fresh to his work at once. We thought it better to have them at one place, because some might be at the 100 fathoms, some at the 114, and some at the 124; and they must give signals from one place to another, and that might cause confusion.

9772. Although the five men who come up last may have to wait half an hour, it does not give rise to any angry feelings among them?—Not at all. If the men at the 100 fathoms wish to go at the 100 they are taken out there. The skip is stopped at the level and they are discharged. The skip is then sent to the 120 at once to take up the pairs of men.

9773. (*Mr. St. Aubyn.*) Are the shafts sometimes right down, and sometimes diagonal?—Yes; they are. Two of ours are perpendicular for thirty or forty fathoms from the surface. After that they go on the course of the lode on an incline.

9774. Evidence of this kind has been given, that where the shafts went straight down kibbles were more advantageous than skips; is that your opinion?—No.

9775. The witness also stated that unless the underlie was more than two feet in a fathom kibbles were better than skips; do you agree with that?—No; I can say this, that if there is an underlie of two feet in a fathom, it would be just as bad as one of three or four feet for a kibble, as it must come up rubbing all the way.

9776. Both for convenience and as a matter of economy you consider the skip superior to the kibble?—Yes; considerably. We have no trouble whatever now, whereas when we had a kibble we were always in difficulties. I think you will find that the majority

CAMBORNE.

Mr. J. Cady.
Capt. Pascoe.

6 August 1862.

of agents in Cornwall will tell you so. There may be probably a prejudiced person or two.

9777. What had you in your mine before you employed a skip, a footway or a man-engine ?—A footway.

9778. Have you had no opportunity of comparing the skip with a man-engine ?—No ; but we are perfectly satisfied as to the superiority of the one over the other.

9779. What number of miners go down every day at your mine ?—I think 180 go down every day.

9780. Are there at least 180 miners who work underground every day ?—Yes ; of tributers and tutworkmen, I should say, somewhere about that number.

9781. Each of those men once in 24 hours makes one journey up, and that makes 360 journeys by the skip in 24 hours ?—No ; not by all of them. Some of them are working shallower, and in parts of the mine too far off from the main shaft, to use the skip. It is principally for the tutwork men.

9782-7. Should you say that you make 300 journeys up and down by the skip with the men ?—No, not with the men. Supposing 100 men made use of the skip, there would be about 40 journeys per diem.

9788. How many years have you had the skip in operation ?—About five years.

9789. Has an accident ever occurred ?—We have had a man and a boy killed, but not by regularly coming up at the proper time. They ought not to have got into the skip ; they were cautioned not to do so.

9790. Has no accident ever occurred from the legitimate use of the skip ?—Not one.

9791. Have you ever known an instance in any mine where, when a skip has been adopted, they have employed another means for carrying the men and stuff up and down ?—No.

9792. (*Mr. Holland.*) If properly used you are of opinion that the skip is entirely free from danger ?—Yes ; I ride up and down in it every time, and I think it is perfectly safe.

9793. (*Chairman.*) You have inspected several mines, and you are well acquainted with them ?—Yes; I have inspected a great many.

9794. It has been stated in evidence before the Commissioners that in some cases cold damp is found, have you ever seen that in a mine ?—Yes ; in granite mines.

9795. I believe that is different from what is called poor air ?—Yes.

9796. Can you describe what it is ?—I suppose it must be occasioned by a dense sort of foulness in the air, and granite mines are more subject to it than in the slate.

9797. Is yours a granite mine ?—Yes.

9798. Is there cold damp in your mine occasionally? Yes ; in some places occasionally.

9799. Does the cold damp arise from the rock ?—Yes ; I should think so. We have it more especially in granite than in the killas. It accumulates in the mines where they have not been worked for a long time.

9800. Did you not find something of the sort lately ?—I never found anything myself nor have I heard any complaint.

9801. What means do you take to prevent it ?—We have generally, at every 15 or 20 fathoms, air winzes from level to level, and in some places we have been compelled to force in air by machines, and we have forced it in by a jet of water. We have tried different means, and I think that a jet of water is a very good thing in many places, especially in rises.

9802. What is the deepest level at which you are now working ?—At 154 fathoms level, or 176 fathoms below the surface.

9803. Have you found any cold damp there ?—No.

9804. When were you down in that level ?—It is about a week ago since I was down at that level. I should have been there if I had not been away. I generally go there once or twice a week.

9805. You cannot state with regard to the last week whether any cold damp has been found there or not ?—I never heard of any.

9806. Would it be reported to you if there was any? —Yes ; but we have never had any complaints from that level at all. It is more especially in some places where they have not got circulation.

9807. How do you judge whether it is cold damp or poor air ?—You will find that the candle will burn very well.

9808. Although there is cold damp present ?—Yes.

9809. Does it rise beyond a certain level in the mine ?—Yes ; it is throughout the place of working ; there is no question about it. If the men ceased long from work they would feel a coldness come over them ; but generally speaking we have good communications ; several shafts.

9810. (*Mr. Kendall.*) Where have you seen the worst effects produced by this cold damp ?—Sometimes in winzes, when they have been sinking down below the levels, or in rises.

9811. But principally in the winzes where they have not been working for some time ?—Yes ; it accumulates there.

9812. Have you ever seen it in a rise above ?—Yes.

9813. And has the effect been the same as in a winze below ?—Yes.

9814. (*Mr. Holland.*) Has it not been found in a level ?—Yes.

9815. What is the peculiar feeling that is produced if you are in it ?—You feel a chilly coldness come over you if you stop.

9816. Do you find any difficulty in breathing ?—Not at all.

9817. Do you think it affects the health of the miners ?—Yes ; if they continued in it long, I should think it would.

9818. I think you say that it only arises when men have ceased to work for some time ?—No ; sometimes it is when the men are employed daily in it ; but in the levels we try to do all we can ; sometimes there is a current of air through a level ; but it does not ascend or descend, and sometimes we try to use means to get it up.

9819. Are these cold damps of frequent occurrence ?—No.

9820. Are they of rare occurence ?—Yes, they are.

9821. Poor air is never found except in mines which have been worked ?—Yes.

9822. Is it not exclusively found in mines which are worked ?—No.

9823. Do you think it ever occurs in mines which have not been worked for some time ?—I think so ; in many mines which have not been worked it is very dangerous to go into them at all.

9824. (*Chairman.*) Can you point out the difference between cold damp and poor air ?—In poor air a candle will scarcely burn ; but in cold damp it burns very well.

9825. (*Mr. St. Aubyn.*) Cold damp has no effect upon the candle ?—A very little indeed ; you would think you had capital air by looking at the candle; it does not even waver sometimes.

9826. (*Mr. Holland.*) Does cold damp ever produce a feeling of faintness ?—Not that I am aware of.

9827. (*Chairman.*) Do you think you could procure a bottle full of this cold damp ?—I do not know whether we could now ; but a bottle might be put down.

9828. I suppose it is not very commonly met with ? —No ; our men are now tolerably healthy.

9829. (*Mr. Holland.*) Is a miner of 40 years of age, generally speaking, a much more skilful miner than one of 30 ?—A man who has been working underground all his life up to the age of 30 ought to be a skilful miner.

9830. Would he be as skilful as a miner of 40 ?—Pretty nearly.

9831. Can men of 30 generally climb as much as 100 fathoms without suffering distress ?—No, they cannot.

9832. Could they climb as much as 50 fathoms at that age without suffering distress ?—No ; they would require a stopping place.

9833. Do you consider it of great importance that all mines as deep as 50 fathoms should be supplied with the means of lifting up the men ?—If they employ a skip to draw the stuff, it is of great importance to land the men with the same ; we find great use in a skip in case of an accident. We brought up a man who was injured to the surface in a quarter of an hour from the time that he was injured, who otherwise, I have no doubt, would have died ; we also use it instead of a capstan, as it saves much expense in taking down and putting up our pumps. We have to employ, perhaps from 18 to 20 men at the capstan, and it would take at least five hours to change the pump, to take it down and put it up, and we do it now in an hour and a half without the men.

Note to 9716.—The wire rope now in use was put on in July 1857, and for the five years previous to that date the cost of chain, kibbles, &c., used was 1,142*l.* 1*s.* 2*d.*; estimated cost of repairing shafts, stands, &c., 300*l.*; smith's cost for ditto, at 50*s.* per month, 150*l.*: total 1,592*l.* 1*s.* 2*d.* For the five years ending July, 1862, the cost of the wire ropes, skips, &c., had been 773*l.* 10*s.* 1*d.*; repairs of shaft, 25*l.*; depreciation of stock, &c., 75*l.*: total, 873*l.* 10*s.* 1*d.* During the former five years the ore sold amounted to 20,836 tons; and during the latter five years it amounted to 21,564 tons. In addition to these results, which were so much in favour of the new system, he put the number of men drawn up by the wire rope and skips at 40 per diem, or 1,300 per month, which he calculated as equal to 780 tons per annum, or nearly 4,000 tons for the five years.

The witness withdrew

Captain JAMES POPE examined.

9834. (*Chairman.*) Of what mine have you charge ?—Huel Basset.

9835. Have you charge of any others ?—South Basset and East Basset.

9836. You have sent in a return of the number of men employed ?—Yes.

9837. Are those mines copper or tin ?—Both.

9838. What is the deepest level at which you are working now in South Basset ?—75 fathoms below the adit.

9839. And in East Basset ?—110.

9840. How do the men ascend and descend ?—They climb ladders in both mines.

9841. Is the mine granite or killas ?—South Basset is granite ; East Basset is killas.

9842. Is there any difference in the temperature of either mine ?—Very little.

9843. Are there any ends which are close or hot ?—Yes, one in East Basset, the 110 fathoms, is close at this moment.

9844. Do you know the heat there ?—No.

9845. How far are you driving that level off a winze ?—It is about 10 fathoms off a shaft, there is not a winze yet, in about eight fathoms more we shall begin to intersect the lode, and then we shall put a winze.

9846. Have you any artificial means now for putting in air there ?—The air is very good, we can accomplish the work very well.

9847. What do you mean by a close end ?—The air is not quite so good and there is not a proper ventilation ; all the ventilation that we have is what comes from the engine shaft. The engine shaft is divided into two parts, so that it will give a ventilation for 20 fathoms tolerably well.

9848. Does the candle burn well ?—Very well.

9849. How do you judge that the air is not quite so good there ?—We generally find that by the burning of the candle.

9850. In the end where you say it is close, will a candle burn well ?—Yes.

9851. (*Mr Holland.*) Then why do you call it a close end ?—By the temperature, you can feel that the temperature is hotter there than in other places.

9852. (*Chairman.*) The candle has to be put on the side a little, I suppose ?—In some places, but not there.

9853. In any other places in that mine ?—No, not at present.

9854. Do you think it likely to be so when you get further from the shaft ?—No, I do not see that it will; we shall have a winze to communicate.

9855. But before you communicate with the winze ?—No, we can accomplish it very well.

9856. How long does the powder smoke take getting out from that end ?—Perhaps about ten minutes.

9857. Not more than ten minutes ?—No.

9858. (*Mr. Kendall.*) When you use the words "a close end," you mean not a close end but a hot end ?—Yes. The miners call it a little close.

9859. (*Chairman.*) When the miners say that it is a little close, do you take any additional means for putting in air ?—Not latterly.

9860. Why not ?—At one time we only had one shaft, and then we were obliged to put in an air machine until we had a proper communication with another shaft.

9861. And now you think that the ventilation is very good ?—Yes ; it depends upon the way of the wind, sometimes it will go down one shaft, and sometimes down the other, but it goes down one and comes up the other.

9862. Have you ever observed whether it changes suddenly ?—Not very suddenly.

9863. (*Mr. Holland.*) Does it change frequently ?—Yes ; when the wind gets south, the mine appears a little closer than when it is north, it is not so fresh.

9864. Do you mean that when it is warm weather the mine is closer than when it is cold weather ?—Yes ; we always find that in the summer season it is closer than in winter.

9865. When it is a south wind it is warmer ?—When it is a south wind it is warmer than with a north wind for any length of time.

9866. (*Chairman.*) You have no means of judging of the air except by the candles I suppose ?—No.

9867. Have you more tutwork men or tribute men ?—The numbers are much the same as when the report was sent. I believe that there are one or two different, but nothing more than that.

9868. Do you use a skip or a kibble for drawing ?—A skip in part and in some part a kibble.

9869. Do the men go up in the skip ?—No.

9870. Did they never try to go up in the skip ?—They have occasionally gone up, but we do not allow it.

9871. Which do you consider cheapest for drawing, the skip or the kibble ?—The skip.

9872. Have you ever made any comparison of the cost of the kibble and of the skip ?—No, I do not know that I have ; I should think that there would be more than one third part less with the skip than with the kibble, or about that, on the average.

9873. What is the description of shaft where you use the skip, is it underlie ?—There is some perpendicular and some underlie. I think that there is the greatest difference in the underlie.

9874. (*Mr. Holland.*) How much underlie ?—From one foot to three feet in a fathom.

9875. The greater the underlie the greater the advantage of the skip ?—I should say so.

9876. (*Chairman.*) Have you any reason for not allowing the men to go up in the skip ?—We are fearful that an accident will occur.

9877. Is it wound with a chain ?—Part chain and part rope.

9878. The skip is not fitted for men ?—No, it is fitted for nothing but for drawing stuff.

9879. Have you ever had any idea of applying it for the men ?—No, not in our mines. In some of the mines the men sometimes go down in it, but there have been a few slight accidents, and perhaps that causes the difference.

9880. (*Mr Kendall.*) Where were the accidents ?—I do not know that I can exactly say where the accidents have been ; it is almost done away with now I believe for men.

9881. (*Chairman.*) Do you know any mine where it is in operation expressly for men ?—No, not expressly. I believe that they use it very frequently at South Huel Frances, but not always.

9882. Have you been down in it at South Huel Frances ?—Yes.

9783. (*Mr. Kendall.*) How do you like it ?—I like it very well, it is much easier than climbing.

9884. (*Mr. Holland.*) Do you consider it quite safe there ?—It appears to be safe as there has been no accident.

9885. Did you see any cause of danger?—No.

9886. (*Chairman.*) Have you had any accident in your mine for the last three years ?—No.

9887. Have your boilers never burst ?—We had one boiler burst, but no accident occurred except the bursting of the boiler.

9888. How did that occur ?—We could not ascertain how it occurred ; we think that it was from the feed not being properly up, from there not being enough water in it.

9889. Have you any other means of ascertaining the quantity of water in the boiler except by the cocks ?—No.

9890. Have you more than one safety valve ?—We have two in some boilers, and only one in others.

9891. Can the men weight the safety valves as they like ?—Yes.

9892. (*Mr. Holland.*) Do they do so ?—We do not allow it, but it may be done.

9893. (*Chairman.*) Have you had any accidents from blasting ?—No, we have had no accident whatever for the last three years.

9894. Do you use any different precaution from what is used elsewhere ?—No ; we have been fortunate in having had very few accidents. I believe that in blasting nearly the whole of the mines are upon the same principle.

9895. Do you use cartridges?—We do sometimes, but seldom ; the men make their own cartridges with us ; they make them of paper.

9896. No they always use that ?—Nearly so.

9897. Do you think that there is safety in that ? — I should say that it is quite as well as the others if the ground is not very wet. If the ground is very wet then we use cartridge.

9898. Does a cartridge of that sort prevent the powder lying about the mouth of the hole ?—Yes, but it is seldom used ; when it is bored down, if the hole is dry they do not use the cartridge.

9899. Then if it is not swabbed out properly there is danger of powder lying about ?—Yes.

9900. That is a cause of accident ?—Yes.

9901. Did you ever hear of an accident being caused by air getting in between the tamping ?—A hole went off once when I was a young man, but I could not account for it. I blasted a hole once, and it did not heave its burthen. I went to tamp it a second time and it went off. I cannot tell how it did not do me much injury.

9902. Was that before the safety fuse was introduced ?—Yes ; that was when we used quills.

9903. Do you not think that the fuse might have been alight although you were not aware of it ?—I do not know how it occurred, because a new charge was put in the hole and newly tamped up. The old charge was blown out of the hole ; I put in another charge, and tamped it a second time, and it exploded.

9904. (*Mr. Davey.*) Did it do anything on the first occasion ?—Yes ; I think there was a crack in it, and I suppose that there must have been powder in that crack.

9905. (*Mr. Holland.*) Did you use an iron tamping tool ?—Yes.

9906. (*Chairman.*) Do you suppose that in tamping with an iron tamping rod there would be any powder mixed up with the tamping ?—There was a crack in the hole, and I suppose that the tamping iron must have struck fire against the rock and have ignited it ; that is what I suppose ; I am not certain about it.

9097. It would be desirable to have a tamping rod which would not strike fire ?—Yes ; that would be the best means.

9908. (*Mr. Holland.*) Did you ever use such ?—No.

9909. (*Chairman.*) Do the men use oak sticks ?—No ; the swabbing sticks are deal principally.

9910. They have only the swabbing sticks to put in, they have no others ?—Just so.

9911. Do you use any patent powder ?—No.

9912. What candles do you use ; do you use any patent candles ?—No, we have the candles from the different chandlers about the county.

9913. What are the men charged for the candles ?—I think the price is now 5*s.* 6*d.* a dozen lbs., but we generally charge them a little more than that.

9914. How much do you charge them ?—7*s.*

9915. Are they limited to any quantity ?—Yes ; 2 lbs. per man per week.

9916. Do you know what is the charge for powder?—It is now 50*s.* a cwt.

9917. What are the men charged for it ?—8*d.* per lb.

9918. Have you any charge for the barber in your mine ?—Yes.

9919 How much ?—3*d.* per man per month.

9920 Do the surface men pay that ?—Yes.

9921. And the underground men ?—Yes.

9922. (*Mr. Holland.*) How old are they when they begin to pay ?—As soon as they become established as men, some as low as 15 or 16.

9923. Although they have no beard ?—Yes ; although they have no beard they pay sometimes.

9924. (*Chairman.*) As soon as they take a man's share of work they pay ?—Yes.

9925. What club money do they pay ?—6*d.* a man.

9926. Is that club money for visible hurt or for sickness ?—For visible hurt.

9927. What is the doctor's fee ?—6*d.* per man per month, that is including sickness as well as hurt in our mine.

9928. Is a separate account kept of the club money ?—Yes.

9929. Do you consider that club money in case the mine was stopped to belong to the adventurers ?—Yes.

9930. (*Mr. Kendall.*) Why ?—In case more accidents occur than the club is sufficient to pay, the adventurers advance money and pay for them, and if there is any little balance in hand I think that they ought to receive it.

9931. (*Chairman.*) At present is there any balance in favour of the adventurers ?—Yes. I cannot tell exactly the balance at Huel Basset, but it is somewhere about 100*l.* I think.

9932. I suppose that if the balance is the other way it is on account of more accidents ?—Yes ; sometimes it leaves a balance and sometimes it is otherwise ; if it is against the mine the adventurers advance money to support them.

9933. Has the mine ever been in a position that you have had to advance money from the adventurers to pay ?—Not since I have been in Huel Basset, indeed I think that we have given the men new underground clothes once or twice out of the club money, such as an underground shirt, and so on ; it has been once or twice done.

9934. Supposing that you had a large balance in your favour, should you be justified in applying that money for men who were off work from sickness ?—

No; according to the rules of our club we could not do that; sometimes it is done.

9935. Have you ever done it?—No; I believe that it is done in some mines.

9936. (*Mr. Holland.*) Do you pay burial money out of the club?—We have done so some past years—but latterly it has been very little; not more than a pound or two a month is paid now.

9937. Then latterly has the fund been nearly all exhausted?—No; we have more than 100*l.*

9938. (*Chairman.*) How are the doctors appointed?—The doctors are appointed by the adventurers at a meeting generally.

9939. How many doctors are there?—I think three in Huel Basset.

9940. Can the men select which doctor they will go to?—The doctor who is nearest generally attends upon them.

9941. It is divided into districts?—Yes; they divide the money between them, and the nearest doctor generally does the work; but the doctors generally agree with each other; they never refuse, and the men generally go to the doctor that they like best; the doctor who is liked best will have most work.

9942. Have you ever had a boiler accident?—Never but one, and that was through the bursting of a boiler.

9943. Do you know what proportion of the money is paid to the men in notes and in change?—I think two-thirds is paid in notes and one-third in cash.

9944. When the men are paid in notes where do they get change?—They frequently go to some inn and get change, and some of the men who are in tolerably good circumstances keep money in their pockets on the pay-day and change the notes for the others, because they can change all the local notes in any market town.

9945. (*Mr. Kendall.*) You say that two-thirds of money is paid in notes?—About that; but I hardly know the proportions.

9946. You say that these notes are generally changed at an inn, or somewherk?—Yes; they generally go to market on the market-day, and they change their money for thoir proxisions.

9947. If they change a 5*l.* note at an inn, is there any understauding that they are to drink so much of tne 5*l.* note?—No; the men on the pay-day generally have something to drink; a glass of ale or a glass of grog.

9948. But it is not an understood rule that they are to spend at least 1*s.* out of 5*l.*?—No; there is no understanding whatever that I am aware of.

The witness withdrew.

Captain JOSEPH COCK examined.

Capt. J. Cock.

9949. (*Chairman.*) Who is the head clerk of your mine?—Mr. Henry Burchett.

9950. Of what mine are you agent?—St. Day United.

9951. You have sent in a list of the men employed?—Yes.

9952. What is the deepest level at which your men are working?—164 fathoms under adit.

9953. How do the men ascend and descend?—By means of ladder footways.

9954. What distance is there between the staves?—We have four footways, two of which are 11 inches between the staves, and two a foot between the staves.

9955. Which do the men prefer?—They take the foot generally, for speed I suppose; they are both very good footways.

9956 Have all the footways the same inclination?—Yes; about the same; there is one footway nearer to their work.

9957. (*Mr. Holland.*) What is the inclination of the ladders?—They underlie.

9958. About how much?—About two feet in a fathom.

9959. Both the 11 inch and the 12 inch?—Yes; that is from a certain level below adit; 30 fathoms below adit where the under-lie comes in.

9960. (*Chairman.*) How do you draw up your stuff, by skips or kibbles?—We have two skips in the mine, and we have kibbles.

9961. Do the men come up in the skips?—I never heard of any.

9962. Which is the cheapest, drawing by skips or by kibbles?—I think that, if properly carried out, skips would be preferable.

9963. They would draw at a less cost?—I suppose that they would.

9964. Do you think that the skips could be made for the purpose of taking the men up and down?—It could be done; but I should not advise it.

9965. Why should you not advise it?—For two reasons: first, I consider that no chain nor rope which might be attached to the wym is adequate to the work, for safety; and secondly, I fancy that men would be too impatient, and would go in too many, as there would be no agent to protect or detect them in going up, and even if the rope be strong enough, they might have their limbs broken by coming in contact with some timber or ground in coming up.

9966. I suppose the men could be detected when they came to the surface if too many came up?—Yes, of course.

9967. (*Mr. Holland.*) Surely that could be prevented?—You cannot prevent men 100 fathoms underneath.

9968. You might spale them if they disobeyed your orders?—It is useless to spale a man if he is killed. You may fine a man a pound, and yet he may think that the agent is out of the way, and say "I will go up this way."

9969. (*Chairman.*) Do you think that the men would prefer the skip to the ladders?—I think not.

9970. Not if they were allowed to go up in the skip?—I never heard of any in our mine who felt any inclination to do so. I never knew a single man to come up in that way yet.

9971. What weight do you haul up by the skip?—The skip is 7 cwt., and the stuff is somewhere about 12 cwt.; that makes from 19 to 20 cwt.

9972. Supposing that four men came up in a skip, what would they weigh?—Clothes and all, we will say perhaps 1¾ cwt. to a man.

9973. Would not a rope, which was strong enough to haul up the material, be strong enough to haul up the men?—I have known a full skip to come to grass, say with a ton, and I have known the same chain to part in going down empty with the 7 cwt.

9974. Have you ever used a wire rope?—No.

9975. With a chain everything depends upon one link; one link is the strength of the chain?—Of course.

9976. If you could get a rope as to which there was no chance of its breaking, and if it did break the skip would not go to the bottom, would you not advise the use of it?—I do not know where we could get that.

9977. You have never seen it?—I have heard of ropes and cables being very strong, to hold, as it has been said, the world, but they have parted.

9978. Did you ever hear of a catch in the skip, so that if the rope broke it could not go down?—Yes.

9979. Have you ever seen it?—I have seen it and have seen it slip the catch. It is not a safe way in any manner I should say. I would not recommend that.

9980. You would not use it yourself?—I should not like to do so.

9981. You would prefer climbing the ladders?—I would rather do it.

9982. What height of ladders would you climb sooner than go up in a skip?—Any length of any mine in this neighbourhood, to any depth; say 300 fathoms, for instance.

CAMBORNE.

Capt. J. Cock.

6 August 1862.

9983. Does climbing affect you?—It does not affect me.

9984. Do you think that men are affected by the climbing?—Yes; if they climb too fast. It is like working too hard, or eating too much meat. If a man does anything to over-burthen himself, of course it injures him.

9985. What is it which you think affects miners' health?—Of course I have my own opinion upon it, but I do not mean to say that I am right in all cases. I think that men often drink a little fast and injure their health, and sometimes they stay a little too long without meat, which is injurious to health. And another reason is, that I believe they climb too fast. But taking it moderately in eating and drinking and climbing, I think that miners have a chance of living pretty long. Sometimes I think that foul air does it.

9986. Have you ever worked in foul air yourself?—Yes.

9987. What was the effect?—I never felt any bad effect.

9988. Have you ever heard of men being affected by it?—Yes.

9989. How does it affect them?—In different ways. Sometimes they feel weakness in their limbs. They sometimes complain of weakness in their knees, and sometimes complain of their stomach. They have no appetite for meat and such like, and then they gradually decline away. A shortness of breath comes on; there appears to be a contraction of the lungs; and they are unfitted for labour and for working.

9990. Has it come on suddenly with any man that you know?—Gradually.

9991. Do you know any man now affected in that way?—If I brought my mind to think a bit no doubt I should be able to name some.

9992. Have you had any ends with foul air in the mine of which you now have charge?—I do not remember any. Our mine is well ventilated. I suppose that there is not a mine in the county of Cornwall better ventilated. We have upwards of 100 shafts from the surface to a certain depth in the mine.

9993. (*Mr. Holland.*) At one mine?—Yes; in the United mine; there are three or four mines united.

9994. (*Chairman.*) In any of these mines does the timber decay?—In some places.

9995. Is there a white fungus?—A white fur, but we see but little of it. I have seen it in Tincroft more especially. I was agent there for two years and three months, and there I saw a good deal of it. In our mine there is but very little. It is a rare case to see it. We have a very strong air in our mine.

9996 The timber does not go so fast where there is a strong air as where it is close?—No.

9997. Have you ever seen what is called cold damp?—Yes.

9998. In the mine of which you now have charge?—No.

9999. What is the difference between cold damp and poor air?—With cold damp a candle will burn bright, but if you stop after perspiring you will feel a chill go through your body. In foul air a candle will not burn; it will go entirely out.

10,000. In cold damp is it worse on a Monday morning, when the men go to work or after they have been working?—In some places. It just depends upon the air coming there. I have worked in places where we have been obliged to drive the air out before going to work. We go up with a jacket and beat the air entirely out.

10,001. Have you ever worked where you have been obliged to throw in lime before you went in?—I have seen it done, but I cannot state the effect. I have burnt reed underground in poor air. It is straw, but it is the stiff part of the straw.

10,002. Is that in the case of cold damp or poor air?—That is in the case of poor air—to burn up the poor air. I heard some old miners speak of it, and of course we tried it just to prove it.

10,003 Did it produce any effect?—No effect whatever. I think it made it worse. I would rather light up a coal fire than do that.

10,004. The smoke did not get away?—Straw causes a great deal of smoke and there not being air to carry it away it was of course there, and we were obliged to leave the place for a certain time before it went away.

10,005. The powder smoke also takes some time to get away?—Yes.

10,006. How long does it take for the powder smoke to get away from any end in your mine where you are now working?—In places it will take twelve minutes, from that to a quarter of an hour, and in some places you blast the hole and the men can go to their work immediately, and there is no effect.

10,007. When you are sinking a winze, I suppose that it does not get away so quickly?—Of course when you get down eight or nine fathoms it will lie a little more, but our mine is so ventilated and the air is so strong that it brings it up very quickly.

10,008. Have you ever had an accident in blasting within the last three years?—Yes; one. We had one in May 1861.

10,009. Did you ascertain how that was occasioned?—By putting the tamping rod on the third floor of tamping.

10,010. How is that to be avoided?—We can hardly tell in those cases; some miners have said one thing and some have said another. One of the men was not killed stone dead; he lived about an hour after he was hurt, and he spoke several times; he said that he was tamping as easy as any hole that he ever tamped in our ground, and he did not know the cause.

10,011. He was tamping with an iron tamping rod?—Yes.

10,012. What kind of tamping had he?—I fancy that it was some blue killas beat up fine. I am not certain, but I think that that was it.

10,013. Was the country hard?—Yes; the whole was in hard country, I think 20*l.* per fathom.

10,014. Have you had any boiler explosions?—There was one some four years ago; the tube went together, the case, I believe was not affected; that is the only case which we have had.

10,015. Is the water good?—Our condensing water is very good; we get it from the granite rock, it is pure water; I believe that it is good to drink.

10,016. Had the boiler which exploded been in use for some years?—Yes.

10,017. How often are your boilers cleaned out?—Just when the engineer thinks proper; sometimes in two and sometimes three months.

10,018. There is no periodical examination of them?—No; we have an engineer in the mine, and of course he has command over those affairs.

10,019. Do you use any patent candles?—We use the hard grease, and sometimes it is of a softer nature; we get some Palmer's candles, the men do not like them very well.

10,020. For what reason?—Because the wick is not large enough.

10,021. They cannot blow it in when it goes out?—If it goes out it must stay out, unless they have a match to light it.

10,022. Has each man a supply of matches in his pocket?—One or more generally have matches.

10,023. But not all of them?—Not all of them.

10,024. What are the men charged for candles?—I think 8*d* a pound.

10,025. What are they charged for powder?—Eightpence a pound, I think.

10,026. What club money do they pay?—One shilling a month; that is for doctor and club.

10,027. Are you aware whether there is any separate account kept of the club money?—Yes; there is.

10,028. Do you know anything about the state of the fund of the club money now?—No; the purser has to do with that.

10,029. Is there any charge for the barber in your mine?—No.

10,030. (*Mr. Holland.*) Have you any other objection to the men riding in a skip, except the idea of

their being injured ?—I never saw a wire rope nor a chain that I would trust myself with.

10,031. Is it not very difficult to prevent the young miners climbing too quickly? Do they not frequently climb too quickly ?—Of course, when they first commence.

10,032. Do you think that a good deal of disease is produced by quick climbing ?—I do not know that; I am sure that I could not answer that question. Miners are, of course, in the habit of getting up as fast as they can.

10,033. Are miners an unhealthy class of men ?—Our men are very healthy.

10,034. But are not miners as a class very unhealthy? —Taking them as a general rule, of course they do not live as long as men who are accustomed to be in the pure air.

10,035. Is not climbing one of the causes of their not living long ?—It may be; our doctors do not say much about that; it is the foul air more especially. I take Dr. Arthur to be of as great experience as any in the county, and he is a very clever man.

10,036. Do I understand you to mean that quick climbing is not a frequent cause of disease ?—Not a frequent cause. If you over-climb or over-eat yourself, or over-do yourself, it is injurious; it is like a horse, if he is running too fast he will not be so well afterwards.

10,037. If it be proved that a very small number of accidents do happen with well regulated skips, would your objection be removed ?—I should not like a skip at all.

10,038. If it be proved that very few accidents do happen to men who ride in well regulated skips, would your objection to riding in skips be removed ?—I think that there are two or three objections which arise against it. If you could ensure my life in coming up, of course I should have no objection to it. A very small proportion of those who go down the ladder are killed.

10,039. (*Chairman.*) But there are some who fall away from the ladders ?—Yes; they may be taken giddy.

10,040. (*Mr. Holland.*) How many are killed indirectly by disease produced by climbing ?—I cannot tell; we have heard that in coal mines a great many have been killed who have been coming up in skips; the rope breaks and away go the men, and they are dashed to pieces; and we have seen and heard of some who have been killed coming up by the man-engines.

10,041. (*Mr. St. Aubyn.*) And you have heard of some who have been killed coming up the footways ? —And some have been killed coming up the footways.

10,042. (*Chairman.*) I see that by the return, several men have been killed by falling from one level to another, falling from the 70 fathoms to the 150 fathoms; how does that happen ?—Sometimes it happens in the dark, there being no light.

10,043. Several have been killed in that way ?—There have been a good many boys and some men. I believe that in nine cases out of ten, men and boys too are killed by heedlessness, by not taking proper care.

10,044. There must be some place for them to fall through when they fall ?—Of course the shaft is there.

10,045. If they are said to fall from one level to another, that would not be falling through the shaft, would it ?—You could not fall through a winze from the 100 to the 170 fathoms.

10,046. But there is one case of falling from the 160 to the 190 fathom level, how would that happen ?—That must be through an open shaft, of course.

10,047. Or a winze ?—No winze, but an open shaft.

10,048. (*Mr. Davey.*) Are the man-engines looked upon with favour by the miners ?—I have no doubt that they are.

10,049. Would you erect one ?—Yes, if I saw a proper place and had the capital to do so. I have no objection to them.

10,050. But you do not think so much of the benefit of a man-engine as to put yourself out of the way to erect one ?—In our mines, where they do not work more than two or three years standing, it is hardly worth while.

10,051. (*Chairman.*) What do you mean by that ?—In a mine which will not stand to work more than wo or three years, it is useless to put up a man-engine; many mines do not work more than two or three years before they stop.

10,052. (*Mr. Davey.*) In your own individual mine, at St. Day United, would you put up one ?—Very likely we might, when the mine got in a position to do so.

10,053. (*Mr. St. Aubyn.*) You are decidedly of opinion that the skip is an unsafe mode of bringing men up ?—I think so.

10,054. Have you ever been at South Frances ?—I have been there, but not underground.

10,055. You did not go down in the skip ?—No.

10,056. Are you aware that upwards of 57,000 journeys have been made in that mine with the skip since its introduction, and that no accident has occurred from it ?—No, I am not aware of it before now, if it is so.

The witness withdrew.

Captain JOHN MICHELL examined.

10,057. (*Chairman.*) Of what mine have you charge? —Grambler and St. Aubyn.

10,058. I believe that you have sent in to the Secretary a list of the men employed underground?—I have.

10,059. What is the greatest depth of your mine ?—The greatest depth that we are working at present is about 84 fathoms from surface.

10,060. Have you charge of any other mine ?—No.

10,061. Is your mine copper or tin ?—Both. We are working copper now. We get a little tin occasionally; but it is chiefly copper.

10,062. How far are you driving a level from any shaft or winze ?—I think the furthest level that we have from any shaft or winze is about 63 or 64 fathoms.

10,063. Is it close at all there ?—It is a little close, but we have a waterfall throwing in air to the men.

10,064. Is it one of the usual waterfalls ?—Yes, the waterfalls about ten fathoms.

10,065. How long is the smoke getting away there ? —It is not very hard ground, perhaps they fire a hole once in eight hours, or something like that, but the smoke does not stay more than about a quarter of an hour, or twenty minutes. We have put pipes in.

10,066. Before you put the pipes in, the smoke did hang there ?—Yes, we put them in of course for our own advantage as well as the men's, for we find that by putting in airpipes we get our men to work an hour or so longer in the eight hours. There is no doubt about that. I suppose that in ground of 4*l.* or 5*l.* a fathom, it will make 10*s.* or 15*s.* a fathom difference whether we give them good air or not.

10,067. Before you put in the pipes, how did you judge that the air was not good ?—Of course experience tells us when we get into any poor air, because we can tell by the smell, and also by the smoke lying after they have shot the holes.

10,068. And by the candles ?—A little by the candles; but we are not far enough off to judge by the candles.

10,069. Have you anything like cold damp ?—All granite mines are a little subject to cold damps.

10,070. How do you judge of the cold damp ?—We can tell partly by the feelings and partly by the timber; the timber does not stand so well where there is cold damp.

10,071. It decays ?—Yes, it is owing to the decomposed granite chiefly that the cold damp is caused, and it will decay timber twice as fast as otherwise.

CAMBORNE.
Capt. J. Michell.
6 August 1862.

10,072. Can you perceive the cold damp more on the Monday morning when the men have not been down?—No, I think not. I consider that the air has more action on the cold damp because there is less taken up by the men in those places. We do not find that there is more cold damp on Monday mornings with us.

10,073. When you have perceived this cold damp, has it been when you have been sinking a winze or putting in a rise or a level?—Sometimes in sinking a winze or a rise we see a little of it.

10,074. Does it appear in the shape of a vapour?—A small vapour. We see it just about a foot or a foot and a half from the bottom of the level.

10,075. (*Mr. Holland.*) Do you never see it at the top?—No, we find it at the bottom of the level, and if you put a candle at the bottom of the level it will waver just the same as a current of air, while at the back it will burn quite clear.

10,076. If it is always at the bottom of a level and not at the top, how does it get into a rise?—There is more of foul or poor air in the workings above the back of the level. The cold damp is in the lower part of the level, the fresh or good air is in the upper part. When I was a boy I held a candle at the bottom on purpose, and I saw it waver very much, and I used to fancy that it was then good air, but the men told me that that was nothing but cold damp, and that is all in the bottom of the level. In the back of the level it is good air, and the candle will burn quite clearly. The good air has an action to keep the damp out.

10,077. (*Mr. Davey.*) Supposing you are sinking a winze, and you come up on the Saturday and go down again on the Monday morning, will you find any accumulation of damp there?—Yes, we find more in the winze than anywhere.

10,078. Do you find an accumulation there on the Monday morning which makes it difficult for you to work there?—Yes, there is more in the winze than anywhere.

10,079. (*Chairman.*) Are the men's gettings in your mine the same as in this part of the district?—Yes, I think so. I do not suppose that there is much difference in the men's gettings, they generally come pretty well to a level. The men will find out that for themselves. If they find that they can get more in another mine, there they will flock.

10,080. Will they leave a district for that purpose?—Not for a few shillings, because of their house and family; they have some difficulty in removing them; but I do not think that there is a great deal of difference in the men's wages.

10,081. Are the earnings of the men pretty equal?—The tributors generally get a little more than tutwork men; but there is a great deal of difference in men in gettings, because there is a great deal of difference in the work—in their practice and experience—some men get wages where others would scarcely get anything.

10,082. It is an advantage to have an experienced man?—Yes. I am sorry to say that a good many of our experienced men have emigrated.

10,083. Do those whom you have now earn enough to live well?—Yes; they average, I should think, about 3*l.* a month.

10,084. I suppose that there are a good many who do not earn that?—A good many do not earn more than about 50*s.* or 55*s.*; but a good many earn 3*l.* 10*s.* and 3*l.* 15*s.*

10,085. In the case of those who only earn 50*s.*, is that enough to live upon?—They are chiefly young men; a married man who has any care and thought about working need not work for less than 3*l.* a month.

10,086. If a man has a bad pitch, he may not earn money for two or three months?—Some men will take a pitch on speculation; and if a man is of opinion that there is ore in that pitch, he may work for six or twelve months and only just get a bare living.

10,087. How does he live during that time?—If he goes and speaks to the shopkeepers that he deals with, they stand by him.

10,088. Do they trust him?—They will trust him for months if they know that he is honest.

10,089. Do you think that the shopkeepers trust the men much?—Yes; very much.

10,090. Do you think that there is always a month of the men's wages in hand?—I believe that it is pretty general.

10,091. Is it so with you?—A good many of our men are so.

10,092. Does not it necessitate, when they first get to work, going to the shop?—Whenever they get work they go to the shop I believe; but some men never do that, they go with ready money, and they live very much better. I believe that a good many of the shopkeepers get 20*s.* for every 15*s.* worth that they sell, because if you are in debt to them you must take the article which they wish to sell or get nothing.

10,093. So that if a man goes fresh to a mine, and does not get any money for two months, he must go to the shop to a certain extent?—He comes from another mine.

10,094. But suppose that he is out of work?—Then he must have subsist. Where a man is in debt he cannot find fault with weight or anything.

10,095. (*Mr. Kendall.*) You have said that if a man is a prudent man he need not get less than 3*l.* a month; you mean to say, I suppose, that if he likes it and wants to be sure of his money, if he goes upon tutwork he can get his 3*l.* a month?—Yes; there is no fear of that.

10,096. But if he chooses to speculate with the chance of getting 5*l.* or 6*l.* a month, on the possibility of not getting 30*s.* a month, that is his own look out?—Yes; we give a tribute according to what we think that a man ought to get as wages, 3*l.*, 3*l.* 10*s.*, or 4*l.* a month; but if he goes to pitches where there is 12*s.* or 13*s.* in the month, it is a speculation. If he meets with a bed of ore he will get 20*l.* very quickly, but he may not get 20*s.*; but of course he is not obliged to keep there.

10,097. (*Mr. Holland.*) Is it a very rare thing for a man to be on starving earnings for several months?—A very rare thing; he may do very badly for two months, but scarcely ever for four; he may once upon a time, but it is not general. In setting a pitch, no agent wishes a man to get nothing.

10,098. (*Mr. Kendall.*) Did you ever know them cut it down to a halfpenny a month?—Yes, and to nothing. I have myself taken a pitch for ten weeks for nothing.

10,099. In order to get into the work?—In order to get into the work in the next two months in that particular pitch.

10,100. It is put up at a sort of Dutch auction?—The limits are called out; perhaps there may be 300 or 400 people, and each will call out some amount of money—some a farthing, and some nothing. I recollect that we, four of us, called out nothing, and we had to work for ten weeks for nothing; and we broke 600 kibbles full and brought it to the surface for nothing.

10,101. What did you get your next take?—I think that we had 5*s.* 6*d.* the next take.

10,102. Did you get good wages then?—I think that we got about 7*l.* or 8*l.* a man per month—that in the four months just made the difference. Sometimes you may get a little more, and sometimes the next two months may not be more than on an average. Of course, that is not the agent's fault—it is the fault of the man who takes the bargain.

10,103. (*Mr. Holland.*) Can those who take bad pitches live on credit pretty well for a time, or are they badly off?—They live pretty well.

10,104. There is no half starving during that time?—No. Of course, if they do badly for eight or ten months, they pinch themselves, especially where they have a large family; but that is not general.

10,105. Is it a common or a very uncommon thing for tributors to be badly pinched?—Very uncommon if a man is willing to work.

10,106. (*Chairman.*) Tutwork men have stead

CAMBORNE.

Capt. J. Michell.

6 August 1862.

earnings?—Much more steady than tributers; but there is a good deal of difference there; when you set a bargain, you set a price according to what you think they ought to have a fathom, or what they ought to drive in one month. If they do not work, or the ground proves unfavourable, of course they do not get so much as you calculate upon, but nine times out of ten they get their 3*l.* or 3 guineas a month.

10,107. You think that the miners have quite enough to live well on?—Yes, it appears so, for a more independent set I have not seen for many years, they are growing so every year.

10,108. Compared with what other men?—I cannot compare them with any other men. You can scarcely speak a word to them; if you do so, they will give up their place and go to another, or will stay out of employ for a month.

The witness withdrew.

Adjourned To-morrow at half past ten o'clock.

Thursday, 7th August 1862.

PRESENT:

The Right Honourable Lord KINNAIRD, K.T.
NICHOLAS KENDALL, Esq., M.P.
JOHN ST. AUBYN, Esq., M.P.
RICHARD DAVEY, Esq., M.P.
P. H. HOLLAND, Esq.

The Right Honourable Lord KINNAIRD, K.T., in the Chair.

Captain WILLIAM RUTTER examined.

Capt. W. Rutter.

7 August 1862.

10,109. (*Chairman.*) You are captain of the South Crofty mine?—Yes; I am what they call the managing agent, not the purser.

10,110. How long have you been in the mine?—About 29 years.

10,111. You were first underground captain?—Yes, and I go underground now sometimes.

10,112. You have sent in a return to the secretary of the number of men?—Yes.

10,113. Do you know about how many men there are in your mine?—I cannot tell exactly, but, surface and underground, we have about 50 just now. We are now putting up a new engine on another part of the mine, and we have not therefore so many employed.

10,114. During that time have you had more men than that?—Yes; we have had more than 700 or 800 men; more than 1,000 worked in the mine for many years. The mine is now divided. It was then East Crofty, and now it is North and South Crofty.

10,115. Your experience relates to when you had a larger number of men?—Yes.

10,116. With regard to the club money, what amount do the men pay for club money?—First of all, when we commenced with East Crofty, the men paid 8*d.* in the pound; that is to say, if they got 3*l.* per month, they paid 2*s.*, and the merchants gave us a penny in the pound on their bills. After a while we found that we were accumulating very fast, though we were very liberal in club matters, and we reduced it to 6*d.*

10,117. Is the club money confined to visible hurts?—Never in any case with us. The rule says that it must be a visible hurt, but we have always slipped over it as a matter of philanthropy, and we have relieved men when they have been home with severe colds and so on, and have continued to do it all the way throughout. After a while we found 6*d.* too much, and we reduced it to 4*d.* Since then the merchants have declined paying us anything, but we can do very well with 4*d.*

10,118. What allowances do you make to the men? Have you any fixed allowances?—For what we call working pay, if a man is slightly hurt we give him 14*s.* per month, 6*d.* per day. For sick pay we give him 1*l.* 8*s.* per month. If he has a broken leg, for example, we pay for persons watching him, and bandages, and anything that he wants. If he wants a bed or a mattress, or anything of that sort, we have always given it. We have been able to be liberal with the club, and we have done so.

10,119. In case of a man being off work for some time, do you continue to make him an allowance?—Yes; we have had men home for years, who have been fairly worn out in the mine, because miners do not live to be very old. I have stood upon the hill, just where we cross North and South Crofty, many times, to look at the faces of the miners as they came up, and you will see very few old men; it has been sometimes complained of when men have had what we call a holiday. I have said you cannot err much in that. When I heard people complaining of a Whit-Monday or Whit-Tuesday, which are holidays with us, and that they do more harm than good, I have not thought so. With all their holidays, they die off very early, prematurely. If you stand at any place in the mining district, and look at the men as they pass by, you will find very few old men.

10,120. With regard to the club money; is the 4*d.* in the pound charged to men even with small gettings? What limit have you?—It goes in the same ratio whether it is 1*l.*, 2*l.*, 3*l.*, 4*l.*, or 100*l.*; it is 4*d.* in the pound. If they get a start, and a man gets 100*l.* (and they have got that sometimes), they pay the same poundage, because they can then afford it very well.

10,121. Does a man who only gets his pound or 30*s.* in a month pay?—Yes; we would rather for him to pay if we gave him a few shillings out of the club afterwards.

10,122. So as to keep up the rule?—Yes.

10,123. Do you consider that 4*d.* in the pound would be sufficient, without the contribution from the tradesmen to maintain the club in the way in which you manage it?—It will do very well for all accidents as far as my experience goes. It would not do to continue on a sick list to every miner, perhaps, but it is done with us, generally speaking. We never turn our backs upon a poor old sick man.

10,124. It must depend very much upon the number of accidents how far the club money will go?—Yes. Sometimes we find that they are more frequent than at other times, but recently, since we have had a fuse and so on, the accidents have not been so many as they were.

10,125. In other mines they pay 6*d.* per month, and in some instances 9*d.* for club money. What proportion would your plan bear to that?—I think that our plan is about 1*s.* per month, averaging it. It is not less than 1*s.*, I should say, but it enables us to step over the bounds of accident. We have sometimes given as much as 5*l.* for a person who has had a defect in his breath, and sent him to Truro, to Dr. Bullmore, or some one else. We could not do that if we were screwed down too tightly.

10,126. You think that with the 1*s.* a month that enables you to relieve sickness as well as hurts?—Yes, in special cases.

10,127. You prefer the plan of 4*d.* in the pound, being in proportion to the earnings of the men, to making a general 1*s.* per month?—The great advantage of the poundage is simply this, that if a man should be successful, and get 20*l.*, 30*l.*, 40*l.*, 50*l.*, 60*l.*, 70*l.*, or 100*l.*, he can then afford to help us; it raises the funds.

10,128. Is 4*d.* on the gross earnings or the net

CAMBORNE.

Capt. W. Rutter.

7 August 1862.

earnings?—On the net earnings. We always suppose the club money and the doctor and barber to be the men's own private money. If you asked us to give you the average gettings of our men in the mine, we should give you the average, deducting for materials, but not deducting for club, doctor, and barber.

10,129. At what age do the boys go down into the mine?—The law will not allow a boy to go down until he is 13 years of age.

10,130. What law?—The law which was passed some years ago. There is a law; I am sure of that. He never ought to be allowed to go underground till he is 13 or 14. It is a law which passed somewhere about 20 years ago. We have acted upon that law, under a penalty of 50*l.*

10,131. At what age does a boy working in your mine pay to the club?—We do not require it till he is fairly allowed to go underground.

10,132. Are these payments to the club by men at grass as well as underground?—Yes; they are as liable to an accident on the surface sometimes as underground. There is a little private understanding. If a boy is at the stamping mill, and is hurt, in some cases a trifle, such as 2*d.* a month, has been deducted; but we do not do it; but if we have a boy hurt we always relieve him.

10,133. Supposing that a man takes a boy of 14 underground with him to help him, do their joint net wages pay to the club?—Sometimes they do, and sometimes they do not. If there are three men in a pair, and they want a stiff boy to go down with them to make up the fourth, we then always deduct for a fourth man; and if there is one man and a boy, we call them two, so far as that goes.

10,134. What amount of club money have you ever had accumulated?—When it was East Crofty we had as much as 2,000*l.* once in Mr. Tweedy's bank, but we have always from the beginning kept a separate account.

10,135. What became of that money?—I am very sorry to say that the adventurers devoted some of it to working the mine afterwards. I told the purser there and then, tooth and nail, that they were taking the blood and bones of the men.

10,136. Then you as manager protested against it?—I did. I was not the manager of the mine at the time, but I could not help opposing it. I thought we should not have done it. I would rather have put 1,000*l.* of it to raise an hospital, as we were trying to do at one time.

10,137. I suppose that that is the only time when they have done it?—Yes. As long as I have had the management I have always taken care not to deduct more from the men than would about do, just to keep about 20*l.* balance; that is enough. There is one thing which we have always found in the case of a failure of accounts, we have always found the men willing to put on a penny or twopence in the pound for a little while till we raised the fund again.

10,138. Then in that case you would communicate to the men the state of that account?—Yes. I should say to the men at once, Our club is exhausted; will you consent to put up 2*d.* in the pound, to make it 6*d.* for a little while? If so, hold up your hands; and they do it with a great deal of pleasure.

10,139. You think it very important that a separate account should be kept?—Decidedly. Our account is kept as distinct as possible.

10,140. Is that account laid before the adventurers?—Yes, every two months; at every account meeting.

10,141. You are of opinion that this money belongs to the men, and not to the adventurers?—Most decidedly, I should say. The adventurers are merely trustees on behalf of the men.

10,142. You state that the men die prematurely; from what cause, should you say?—I think the general cause is debility; damp air under ground. I paid attention to it for 40 years, more or less. Every day of my life I studied something about mining. I have been underground longer than that. It is very different now to what it was many years ago. We are more particular in driving our levels, and keeping a dead level in. We do not go up so much on an incline as we did, and we do not drive levels so far now, without sinking winzes, so that the mine is better ventilated. Another thing is, that the ladders and footways are much better; we have seats. When I was a boy we did not think of stopping anywhere; we ran 100 or 120 fathoms like a cat.

10,143. If there is a gradual rise in the level to the height of the level itself the air will not go beyond it?—No. I have many times seen, after a hole has been blasted, that the smoke has been going back about half way down the level, and the air has been coming in under. If you carry your level wide and high, seven and a half feet high, which is the proper level, and what we generally carry, and not less than three feet wide on the average, back and bottom, or perhaps three and a half feet (that is our rule), if you carry a plain surface, the air will finds its way at the bottom, and the foul air will come out at the top.

10,144. Supposing that you drove the level with an incline down, would it have the same effect?—No; air will not run down hill nor water up.

10,145. What do the men pay for candles?—Eightpence with us.

10,146. And what for powder?—Eightpence.

10,147. Is it always the same price?—About the same. They do not cost us so much, but if we did not put a tolerably heavy price on them they would carry them away to barter for tobacco and other things.

10,148. Do you think that that price completely prevents it?—Not completely, but it does, to a great extent.

10,149. What proportion of notes and cash do you pay?—About half.

10,150. Where do the men get the notes changed?—Some in coffee houses and others in the alehouse and shops where they purchase goods.

10,151. Is it not an inducement to go to the alehouse?—Not much; we have very little to complain of in that way in this county.

10,152. The men are very temperate?—Very indeed; you can see that by the houses which you see studded about; occular demonstration is best.

10,153. (*Mr. Kendall.*) How are those houses built; are they on lease?—Yes, on lease for three lives; that is a bad system.

10,154. You prefer a term of years?—Yes, by all means in the world.

10,155. (*Mr. Holland.*) You have stated that there are very few old miners to be seen coming out of a mine?—Yes.

10,156. What do you call an old miner?—A man coming up strong in years; a man of 50 or 60 years is very old for a miner after working underground.

10,157. Are there very few of 50 or upwards?—Very few of 60 underground.

10,158. What becomes of the old miners?—They dwindle down; they waste away in time.

10,159. Do many of them take to other employments?—Some few.

10,160. Do a large proportion take to other employments?—Not a large proportion, but many do for a little while.

10,161. When did you drop the club charge from 8*d.* to 4*d.*?—That was about 20 years ago.

10,162. Does 4*d.* about keep you clear now?—Yes.

10,163. Were your allowances much more liberal when you were at 8*d.* than they are at 4*d.*?—No, we accumulated a large sum then. I do not know that we were more liberal then, than we are now.

10,164. Do you think that miners are much less unhealthy than they were 20 years ago?—I think that, upon the whole, the miners are more healthy now than they were 20 or 30 years ago, because we are more particular.

10,165. And you think that the effect has been very considerable?—Yes, I think I must say that it has.

10,166. Are the miners more careful than they were in keeping out of powder smoke?—I am sorry

to say that they are too fond of going into the smoke too soon.

10,167. Why ?—Because they want to see what the hole has done, and how much ground has been rent off. Sometimes they will go in in a cloud of smoke, and rap away at it the same as if they were going to get 5*l.*; they will do it.

10,168. Does going into the powder smoke produce any evident effect upon them ?—I think that the powder smoke, with the dampness of the air, is one of the causes which brings on premature death with them.

10,169. You think that it irritates their lungs ?—Yes.

10,170. Does it make them cough badly ?—No, not much, but they look very pale.

10,171. Do they suffer much from dust ?—No,

10,172. Do you think that any effectual prevention against the consequences of powder smoke would be very beneficial ?—I think that if it could be laid down as a rule (and I do not see why it might not) that men should not go in so quickly after the explosion as they do, if a certain fine were put on them in the mine, the agents might effect it a little ; but I do not know who else could, because the men are down out of sight.

10,173. Supposing that any simple instrument could be invented to enable them to breathe without breathing powder smoke, would it be beneficial ?—We are obliged to have it in some places, what we call a duck machine, to suck out the smoke.

10,174. To draw it out ?—Yes.

10,175. Suppose that an instrument could be invented to keep the powder smoke out of the men's lungs ?—That would be of service.

10,176. Would they wear it ?—Yes, I think so. I will give you my experience of dusty ground. I have found that neither working in a very wet place, nor yet in a dusty place, ever affected me. I was years that I could not eat a bit of meat underground, having no appetite, but was quite well and hearty. I could jump into the scales, and pull down 9 or 10 score, after working 12 years ; I have done it many times, and have been agent more than 30 years. Dust did not affect me, because I liked to work with my lips closed, and as soon as my nose got pretty well filled I out with it ; but everybody does not do that.

10,177. (*Chairman.*) Why should not men let their beards grow, and wear a moustache ?—It would be a very good thing. You know that Providence has put a net in their nose, a net that will catch the dust, and out with it.

10,178. (*Mr. Holland.*) Men who have not taken that precaution have suffered much more than you have ?—Yes.

10,179. Are you sure of that ?—Yes. When I worked in St. Ives district I lived at Hayle. I went down there every Monday morning, and came home on Saturday afternoon, and they said that I and my comrades did not look like Over Hayle men. It was not drink. I have been for 13 years together and have never drunk anything except water, coffee, and tea.

10,180. Are the men of that district more affected by dust than in other districts ?—No; but they do not work so many hours underground in that district as in this.

10,181. Do the men working in Over Hayle generally look ill ?—Yes.

10,182. Why ?—On account of their working more hours than on the other side. The mines were deeper in many instances.

10,183. Were they very dusty ?—Not particularly dusty. You must go down in the shallow mines, in the clay slate, to get dust; not in the ironstone and granite.

10,184. Are the killas mines more dusty than the granite mines ?—Yes, a great deal ; because there you work pick and gad, and in the others you bore and blast.

10,185. What is your explanation of the granite mines being more unhealthy than the killas mines ?—Because there is more cold damp in granite. I have men now who come over the hill and say, Can you give us a job ; they say they have been working in the granite, but they do not like to be down there so well.

10,186. How does the cold damp affect them ?—The granite in some way produces a colder, sleepier damp than the clay slate does.

10,187. What effect does that produce upon the miners ?—It debilitates them.

10,188. Does it make them more liable to lung disease ?—I am sure it does.

10,189. Is that a prevalent opinion among miners ?—I think so ; it is my opinion, at all events ; miners say so.

10,190. And in your opinion that is in consequence of the greater amount of cold damp in a granite mine ?—Yes.

10,191. And not the greater prevalence of dust ?—No.

10,192. Is there more blasting in granite mines than in killas mines ?—Yes, because you work more ; you work with a pick in killas mines, and blast less.

10,093. May not the effect be partly owing to the less prevalence of powder smoke in killas mines ?—That may be a cause, but if you go into a deep granite mine you will find a sleepy coldness. I have proved that to be the case, and I have heard hundreds say so as well.

10,194. After there has been a blast of powder a great deal of that gas is produced which when cold becomes cold damp. Does that explain it partly ?—That is one reason, I should say, but I do not think that that is all the reason.

10,195. (*Mr. Kendall.*) Your working miner is a very moving fellow, is he not ; he goes from one place to another a good deal ?—Yes.

10,196. They shift very much ?—Some do, and some not. We have some men in the mine who have been there from boys.

10,197. But very few, I suppose ?—Very few ; many do shift. If they are not pleased with their work they go somewhere else where they think they can do better, and very often they come back, and say that they wish they had never gone away at all.

10,198. You say that when your club gets low you let the men know it, and they willingly come forward and pay a higher sum ?—Yes.

10,199. And I suppose they also know when the club is in pretty good condition ?—I suppose they do ; but there is a pretty deal of what we call dignity about the Cornish miners; they do not like to be beholden, if they can do without it.

10,200. When you had your 2,000*l.* balance, I suppose the miners knew it ?—Yes, they knew it very well.

10,201. When men take, they make their calculations ; if they have to pay 8*d.* in the pound, or if they have to pay 4*d.* in the pound, they act accordingly ?—I do not know about that. I do not suppose that that comes much into their calculation, because the object of 8*d.* or 4*d.* in a month is not much ; they suppose that it may be wanted for the club, and therefore they do not grumble about it.

10,202. You do not think that it enters into their calculations at all among their items ?—I do not think that they think much of it ; they think a little of the drawing sometimes ; it comes out sometimes very heavy ; but our drawing is very easy, and it is so in many other mines ; in others, again, it is more heavy.

10,203. If these men do not make any calculation at all, and are constantly shifting, of course, they pay more for their club than they are likely to draw for their club, they are making a nest egg for other miners ?—Yes ; they cannot do themselves good very well without doing good to others.

10,204. You say that the balance belongs to the men, and not to the adventurers ?—I think so.

10,205. If the men shift very frequently, if two-thirds of your men shift, the balance can hardly be said to belong to the men in the mine ?—No. If I work in this mine, and you in that, and we change, we each have the same benefit.

10,206. That would be all very well if you paid

CAMBORNE.
Capt. W. Rutter
7 August 1862.

the same in both mines, but if in one mine you paid 4*d.* in the pound, and in another 8*d.*, and in another only 2*d.* in the pound, which is what is generally paid, there would be a great difference?—Yes, but they do not notice that. I can give you a case which happened once in Redruth. There happened to be two or three deaths, and at last a man said, "All the money will be "got from us if we do not look sharp," and before the next month he was dead himself.

10,207. When a part of the 2,000*l.* balance in that club money was expended, and you thought it right to remonstrate, did the men themselves make any remark on it?—They did not like to grumble about it; they did not bring anything forward specially.

10,208. Was there a feeling of discontent among the men in consequence?—Yes, the men did not like it; I am bound to say that.

10,209. (*Mr. St. Aubyn.*) In your mine do you use a man-engine or footways?—Footways.

10,210. Do you consider a man-engine advantageous where it can be used?—Most certainly. I will give you a case. In Great Alfred, when Mr. Field was the principal, they came down, and put that mine to work. Some years ago he asked my opinion, because I had worked in the mine before. Mr. Field asked me what I thought about working the Great Alfred. I told him, "If you put up a man-engine, and put a machine "to raise the miners, you may succeed, but I would "not give a farthing for it else." For men to come up 300 fathoms, it being very hot down there, is a tolerably tidy day's work, with nothing else.

10,211. How deep would you go in a mine before you began to use the man-engine?—I think the man-engine is of very little use before you are 100 or 150 fathoms deep, and then it is time to get it to work.

10,212. You think that a man, if he did not climb too fast, could come up 100 or 150 fathoms easily?—Yes.

10,213. Have you ever been down the skip at South Frances?—No.

10,214. Have you any opinion about it?—I have an opinion, but still it is my own. I know that in the collieries they go all right on skips. I do not like them.

10,215. But you have never had any practical experience of it yourself?—No. I have seen them down in Sunderland nearly 50 years ago.

10,216. If skips could be made as safe as footways, you would think it an improvement to bring the men up by them?—Yes; it would do very well indeed, if they could be.

The witness withdrew.

GEORGE SMITH, Esq., LL.D., examined.

G. Smith, Esq., LL.D.

10,217. (*Chairman.*) You are chairman of the Cornwall Railway?—Yes.

10,218. And a director of the West Cornwall Railway?—Yes.

10,219. You are a magistrate?—Yes.

10,220. You have been long resident in the centre of the mining district?—Yes.

10,221. I believe you are also working a patent for the safety fuse?—We were the original patentees, and hold a patent for improvements in the manufacture of the article still. The original patent has expired many years ago.

10,222. You have several establishments for the manufacture of the safety fuse?—Yes, in different countries.

10,223. The safety fuse has been of great use in saving the lives of men in blasting, has it not?—Very much indeed. It has diminished accidents to a very great extent.

10,224. There are still accidents from blasting?—There are.

10,225. And sometimes from cutting the fuse?—I have never known an accident to arise from cutting the fuse. I have known the fuse cut, and explosion to take place, but the miners never use tamping so hard, and hammer it so violently very near the charge as to cut the fuse; and as the moment the fuse is cut, if it ignites, the smoke ascends from the hole, they have time to get away to some distance. There must be some warning; even the burning of an inch of the fuse would allow the men to go several yards.

10,226. Have you ever turned your attention to what the accidents which still take place from blasting arise from principally?—I think that the larger number of the accidents now arising from blasting arise from what they call picking out the hole, when the fire is not conveyed to the charge. If the fuse is carelessly inserted into the charge, the tamping settles the charge down so as to separate it from the fuse, and then, although the fuse may have a very perfect action, the fire is not conveyed to the gunpowder, consequently, the hole does not explode, and they pick it out, in doing which they sometimes get to the charge, and mix up the gunpowder with the hard tamping matter, and explosion takes place.

10,227. What instrument do they use to pick out a hole which has not gone off?—A small sharp iron; and sometimes I have known them bore it out with the borer; and I have known them press down the charge with an iron tamping bar in a dry hole, with dry gunpowder at the bottom of the hole, and they have used that instead of a piece of wood.

10,228. Could no instrument be invented to use, either for picking out a hole or for driving the tamping, which would not create sparks by contact with the stone?—My opinion is that a hole never ought to be picked out under any circumstances; and in most of the mines there is a rule to the effect that on any accident occurring from picking out a hole no relief is to be given from the club. I think it is always better that a new hole should be bored.

10,229. But a man having gone to the labour of cutting out a hole, it is natural that he should like to make use of it?—Yes.

10,230. Could you enforce any such rule as you mention?—I am afraid not, so as to make it universally operative. Another cause of accidents is, I believe, the neglect to use what they call a wet swabbing stick, after the charge is inserted in the hole. A great many of these causes would be prevented by the use of cartridges. They very seldom bore the hole perpendicularly, but give it such a direction as shall effect their purpose in blasting the largest quantity of ground. Then if it is put down in a sloping direction, and the charge is inserted by pouring the gunpowder into the hole, the upper part of the gunpowder will of course be considerably above where the surface of the charge is, when it is properly pressed. In every case after the charge is inserted, it should be carefully pressed down until its upper surface is at right angles with the direction of the hole; a first layer of soft tamping should then be put on the charge, and then a damp swabbing stick put in, so as to destroy any grains of powder that may still remain about the sides of the hole. Unless this is carefully done I believe no tamping bar whatever will ensure the safety of the miner. The powder against the sides of the hole would be liable to take fire and convey it to the charge.

10,231. Would copper coming in contact with the lode or the country create a spark?—No; but the pulverising of the tamping against the sides of the hole might.

10,232. (*Mr. Holland.*) You think that the two materials rubbed together might produce fire?—Yes.

10,233. Are you satisfied of that?—I have not a doubt of it. If they used tamping, as some of the mines prepare it, I do not think that that would apply, but I know that hard tamping is used which would strike fire.

10,234. (*Mr. Kendall.*) Supposing that you had a metallic bar which would not strike fire, and that that metallic bar struck off a bit of hard ironstone, and brought it in contact with something very hard, such

as flint, in the tamping material, would those two bits jammed together ignite ?—I have no doubt of it. At the same time I believe that if you had a tamping bar, the lower part of which would not strike fire, you would diminish the cause of accidents very seriously, but I do not think that it would entirely prevent them.

10,235. (*Chairman.*) You think that a cartridge also would be an advantage in the way of safety ?—I think that it would, and generally speaking, I believe the holes being usually damp, the cartridges would pay for themselves in the saving of gunpowder.

10,236. What objection do you suppose would be urged against the general use of cartridges?—Several. In the first place there would be an objection to them on account of their size. The holes are bored of different sizes. Sometimes at the beginning of a *core* the holes are different from what they are at the end, on account of the wearing of the borers, and if a small cartridge is put into a large hole it will crush and break under the operation of tamping. There are several inconveniences which stand in the way, especially as the miners' habits are so confirmed in the insertion of the gunpowder in the ordinary manner.

10,237. Those habits are, perhaps, one of the greatest difficulties to overcome ?—I believe so.

10,238. You have of course seen a cartridge made by the men of brown paper on the spot ?—Yes.

10,239. And placed on a stick which fits into the hole?—Yes, that would obviate the thing to some extent.

10,240. Do you think that there are any other objections which can be urged against the use of cartridges than what you have stated ?—No, I am not aware of any other, save and except the labour of providing them, and the inconveniences connected with them, which I have mentioned.

10,241. I see that a great many accidents occur in mines ; have you ever turned you attention to what are the causes of those accidents, independently of blasting ?—The accidents which usually occur, and which come under my notice, are of a kind to indicate the means of prevention themselves, men falling away from the ladders. Some accidents occur which I suppose no human foresight could deal with at all, such as the falling of stones and loose ground. I have known several men in the last year or two injured and one killed by that means.

10,242. (*Mr. St. Aubyn.*) You do not mean falling down the shaft, but the falling away of the country ?—Yes ; and stone accidentally falling away down a shaft or from the level.

10,243. (*Chairman.*) Are you aware of any accidents happening in this district by falling down a shaft, falling away from a ladder, or by falling from one level to another ?—They cannot fall from one level to another without falling down the shaft.

10,244. Or winzes ?—Precisely so. I have not known of any accidents arising but from persons falling from the ladders.

10,245. Then falling from a shaft or from one level to another has not come under your knowledge ?—No ; nor falling down a winze. I have not heard of any such case recently. As far as I am informed, very few cases occur from the falling away in a shaft ; they do sometimes.

10,246. Are there any accidents from falling down an abandoned shaft, from its being left open at the top, and not protected ?—I think that I have not not known but one such case for many years.

10,247. Is it within your knowledge that there are many abandoned shafts which remain open and unprotected ?—Not many. You find one here and there, but I do not think they are numerous.

10,248. Is there any law compelling the abandoned shafts to be protected ?—I am not aware that there is. I have never known a case in which a representation made to the proprietors of the mine or the mine agents has not been attended to.

10,249. All such cases, I suppose, would come before a coroner's inquest ?—Yes.

10,250. Are you acquainted with the plan adopted with regard to the club money in the mines ?—I do not know anything but what is generally known upon the subject.

10,251. Is it generally considered that the club money is the property of the men or is the property of the adventurers ?—The agents and adventurers look at it as the property of the mine, and the men look at it as their property ; they have quite made up their minds about it.

10,252. Whose property do you consider it to be ?—I really do not know how to answer the question. The allegation on the one side is that it is estimated in the wages ; the allegation on the other side is that it is no more estimated in the wages than other mine cost, as sharpening the borers, or anything of the sort, and that what the men have really to take up as the balance is their wages ; that is what the men say. I cannot give an answer as to where the exact line of property is, but I have a very strong opinion where it ought to be.

10,253. Will you state that opinion ?—I think that the understanding ought to go on the principle that the club money belongs to the men. I think that it ought to belong to the men, and I think that the club money ought to be of such an amount, and the club based on such principles, that it should belong to the men.

10,254. (*Mr. Kendall.*) In case a mine stops with a balance in hand, what is to be done ?—If my opinion were asked upon that subject it would be that in such a mining county as ours there ought to be a central fund for particular cases, and for the relief of such aged and infirm miners as the circumstances of the case would meet, and that all those balances should be appropriated to that object.

10,255. Would it not be a better plan that as long as there were any parties receiving money when the mine stopped, they should receive the money out of those balances as long as they lived ?—I believe that they do not receive more than a year or two at the outside.

10,256. (*Chairman.*) Is that the practice at present ?—Yes.

10,257. Is this money ever applied to purposes connected with the mine ?—Yes ; I have sat at a mine board myself, and seen 300*l.* or 400*l.* balance of the money in the club appropriated to pay merchants bills.

10,258. Did you concur in that ?—I demurred to it, certainly, but I was met by the answer, "What are "you to do with it ? You cannot divide it among "the men, and the men who are now working in the "mine have not been the contributors to it any more "than those who worked in the mine many years "ago."

10,259. Is there any provision made when men cannot work from sickness ?—It is the usual practice, I believe, that when a man is sick his comrades share with him the loss for that taking.

10,260. (*Mr. Holland.*) During the period of the take ?—Yes. If they take for a month or two, I understand that the sick man receives the same as those who are working, until the expiration of that take ; then of course he is not included in the new take, and he receives nothing.

10,261. (*Chairman.*) How is a man maintained who is sick and cannot work, and has not laid by anything ?—He has no resource at all but what he has provided providently for himself. If he has been provident, and joined himself to a provident society, he is in the same position as any other working man.

10,262. How are the doctors appointed ?—By the adventurers.

10,263. Do you think that there is any dissatisfaction among the men at the way in which the doctors are appointed ?—I do not think there is ; I have heard grumbling, but very seldom.

10,264. In your opinion do men suffer in their health from working in the mines ?—My impression is that

CAMBORNE.

G. Smith, Esq., LL.D.

7 August 1862.

there are diseases engendered in consequence of working in the mines.

10,265. Have you any suggestions to make how any of those diseases might be obviated ?—Nothing, but the general remark that any contrivances which would save the men the labour of ascending by the ladders must, I think, have some effect upon them.

10,266. Anything which would benefit the men would benefit the employers ?—No doubt of it.

10,267. How are the schools supported in this neighbourhood ?—By private contributions, with Government aid.

10,268. (*Mr. Holland.*) Individual contributions ?—Individual contributions.

10,269. (*Chairman.*) Do the mines contribute at all to the schools ?—I do not think it is general; but in Camborne we have a very large and I believe a very excellent British school. There are one or two mines which charge the men, I think, 2*d.* or 3*d.* a month, and then they send their children to the school free. There are two or three other mines which contribute from the mine fund.

10,270. Where it is charged is it charged upon all, married and unmarried ?—I believe so. There are other mines which make small annual grants of 10*l.* or 12*l.* a year to the funds of the school, and then they have the privilege of sending children.

10,271. At what age do the children go to work at grass ?—At all ages; from six years old.

10,272. Are there evening schools ?—Very few indeed.

10,273. Should you say that it is necessity which induces the parents to send the children thus early to work ?—It is rather, I think, the family convenience. Perhaps the father and an elder brother are working as tributers, and they have to employ boys and girls ; if they have girls or boys of their own whom they can put on and take care of, and look after and receive the pay for, it serves their purpose better than employing strangers.

10,274. Therefore there are a number of children who have not at present the means of education ?—There are great numbers of them who have no means of education beyond what they get in Sunday schools. The Sunday schools in this neighbourhood do a vast amount of good, and thousands of children are taught to read in them.

10,275. (*Mr. Kendall.*) Have you any idea of the proportion of those who are taught and those who are not taught ?—We have, I suppose, a gross population in this town at present of about 8,000. Our schools number about 1,000 children; that is to say, the Wesleyan schools; and I believe that all the other denominations together would be quite as much. I should think that there are 2,000 children in Sunday schools in the town of Camborne.

10,276. (*Mr. Holland.*) Could it be ascertained accurately ?—Yes ; you can have those figures before you.

10,277. (*Chairman.*) How is it as to the day schools ?—Of day schools there are very few. I do not know how many children attend the National school. I suppose that the British school would have at least 300, or from 300 to 350. I have a very strong impression that the provisions of the Factory Act ought to be applied to all our large mines.

10,278. (*Mr. Holland.*) What provisions ?—Provisions for obliging the proprietors to educate all children under a certain age for so many hours a day.

10,279. (*Chairman.*) At what age do they go underground, generally speaking ?—Some of them go underground very young. I am not very well informed upon that subject.

10,280. Is there any law preventing their going undergound before a certain age, as has been stated here ?—Not that I am aware of.

10,281. (*Mr. Holland.*) Is there a popular impression that it is illegal to send them underground below a certain age ?—I am not aware that there is. When they are put underground young they are almost always taken down by fathers or brothers.

10,282. (*Chairman.*) A great proportion of the children who attend the Sunday school are employed at mines ?—A very large proportion of them. I think there would be no great difficulty in applying the provisions of the Factory Act, which I have mentioned, to all mines employing, say, beyond a certain minimum of men.

10,283. (*Mr. Holland.*) What other provisions would you suggest ?—I have not looked at the matter with reference to any other point.

10,284. Do you think that the hours of labour ought to be restricted ?—No ; I think that the hours for which they are now occupied, if divided between labour and education, would not tax them too much.

10,285. That would be practically a restriction of the hours of labour ?—Yes, precisely the same as in factories, which has operated so very satisfactorily.

10,286. Do you think that there is the same urgent necessity to restrain the labour of mine children as to restrain the labour of factory children ?—I think not. I do not think that the children in mines are physically injured now ; but as the age at which they go to the mines precludes the possibility of their learning anything but what they can learn on a Sunday, and seeing that only reading is taught in these Sunday schools, I think the children should have some other means of education.

10,287. (*Chairman.*) Do you think that a large number of the miners are in debt to the small shopkeepers ?—That is most certainly the curse of the population.

10,288. Does that arise in any degree from their always being a month's pay in hand ?—I am afraid it does.

10,289. You think that a more frequent payment would be an advantage ?—I think that a more frequent payment would be very beneficial.

10,290. Do the miners' families get into debt through the temptations afforded them by travelling packmen ?—Yes.

10,291. Has any means ever occurred to you of putting a stop to that to any extent ?—No, I do not know what could be done in a legislative way to prevent it. These men certainly inflict serious injury upon the comforts and the morals of the people. They go round with their packs, and they exhibit their finery, and coax the women to take it, and tell them that they may pay 6*d.* a month or 1*s.* a month, or anything of that sort, and when once the goods are received they have them entirely under their power, and summon them by a dozen at a time to the County Court.

10,292. Are the parents responsible for the debts incurred by their children to these packmen ?—The debts are generally incurred by the parents, or with their knowledge.

10,293. (*Mr. Holland.*) By the wife ?—By the wife generally.

10,294. (*Chairman.*) Do all these packmen pay licence ?—Yes ; a hawker's licence.

10,295. Do you consider the miners in this neighbourhood temperate or otherwise ?—There is a vast difference in them in that respect. I think that upon the whole you cannot say that they are generally intemperate.

10,296. (*Mr. Holland.*) We were told yesterday that if men would always wet the tamping well when a charge has missed fire they could draw a charge without danger; what is your opinion upon that point ?—I have been told so too, but I very much doubt that.

10,297. You think that the hole ought to be absolutely abandoned if it misses fire ?—That is my opinion. It depends upon the nature of the tamping. If you had some kinds of tamping, like soap-stone, or what they use very often, soft elvin, I believe that if it were tamped down hardly in a hole it would hold water for a month without destroying the charge. I do not think that the water would permeate that solid mass of tamping in any reasonable time, so as to destroy the charge, and then the only course to be

taken is to dig into the dry tamping so far as to allow the water to wet the powder, and in doing that there must always be danger.

10,298. Could not such tamping be safely picked out with a copper tool ?—I do not think it could.

10,299. Would it be just to prohibit by law the picking out of a hole? To make it an offence ?—I should not be sorry to see this done. I have two men now whom I see every week, both stark blind, and they incurred their blindness in each instance, I suppose, for the sake of getting a shilling or two.

10,300. Does not a man endanger other lives as well as his own by picking out a hole?—There are usually two men, and a hole is not picked out unless they both agree to it.

10,301. Are the adventurers careful to appoint doctors who will be acceptable to their men ? Is that a matter of careful consideration ?—I believe it is. In the 40 years that I have been very intimately connected with the mining of this neighbourhood, I have not known but one instance that has excited serious dissatisfaction.

10,302. There is no job in it ?—I think not.

10,303. It is done with a fair view to the men's interests and wishes ?—I believe so.

10,304. Is there generally more than one doctor to a mine ?—Very frequently.

10,305. And have the men a free choice as to which doctor they will go ?—Yes.

10,306. There is no compulsion ?—Not where there is more than one surgery, except the compulsion which geography gives. When in a large mine there are two doctors they are often reside in different districts.

10,307. Would it be desirable to have a wider choice of the doctors of a mine; for instance, to have in a district a number of mines connected together with the same doctors ?—I do not think that necessary.

10,308. (*Mr. Kendall.*) Supposing that, instead of having a couple of doctors employed to superintend one mine, you had a district of mines and a district of doctors, so that each man might employ whatever doctor he liked, and that doctor should take up the amount which that man pays to his mine; how do you think that that would act ? He would then have the nearest doctor, or the man of his choice ?—I really do not know.

10,309. If feasible, do you think that it would act well ?—It might in many cases be an improvement, but as far as my observation goes I have not heard that there is any practical grievance in the present mode of appointing surgeons.

10,310. You have had very large experience, and according to your experience you find that, taking the doctors and the men, they very fairly agree with each other ?—I think they generally do.

10,311. And that the men are very fairly content ?—As far as I am informed.

10,312. I suppose that under any system, there would be a little grievance now and then ?—Most certainly.

10,313. I understand from you that a great number of the children in early life are employed by their parents in certain processes in bringing the ore to market which the parents raise ?—Yes.

10,314. And that leads to their absenting themselves at an early age from school during the week days ?—Yes.

10,315. Have you ever been able to form any idea as to whether this early exposure on the mines is likely to be more prejudicial to their health than if they were allowed to spend their early years at school ?—Yes, I have thought so; and before the passing of the Factory Act I felt very strongly impressed that there ought to be some legislative prohibition of the very early employment of children.

10,316. Even as far as we are concerned in this county ?—Yes; but subsequently to that I have thought that the other solution would be rather preferable.

10,317. Which other solution ?—That is, of insuring to them, say a couple of hours or three hours a day for education on the mine by a schoolmaster appointed by the mine.

10,318. As a question of health, do you think that much disadvantage arises to the children by their being exposed to work early ?—I do not. I do not think that the question of health is a serious one. I think that it is more an educational question.

10,319. (*Mr. Holland.*) The children's labour is not heavy, is it ?—No. In very cold wintry weather they occasionally suffer rather severely.

10,320. (*Mr. St. Aubyn.*) You have been accustomed for a great many years past to observe the condition and habits of the mining population ?—Yes.

10,321. Have you observed within the last 20 years any improvement in their physical condition and in their general health ?—A very great improvement; a very great improvement in their manner of living, and consequently, I believe, in their physical condition altogether.

10,322. From what causes do you think that that improvement arises ?—I think very much from the improved character of their dwellings. I think that that is a very material cause, and consequently they have more cleanliness and better order in their families a great deal than they had when I was a boy, 50 years ago.

10,323. Their food is better ?—Their food is much better.

10,324. You mentioned in the former part of your evidence that the climbing was injurious to them. From what you have observed, do you think that the introduction of man-engines has been of advantage to the working men as regards their health ?—I have no doubt about it.

10,325. Do you know, from your own knowledge, that the ventilation is better in mines than it was now, say 30 years ago ?—I can scarcely say from my own knowledge, except from the improved ventilation of mines, which I know simply from looking at plans and sections rather than anything else.

10,326. You know that mines are better ventilated ?—I know that mines are better ventilated now than formerly.

10,327. Do you consider that that has had a beneficial effect on their health ?—I think so.

10,328. You spoke just now of an association which you thought it would be desirable to found for the relief of miners who were permanently disabled from working; how would you propose that it should be supported ?—I really have not thought of the organization of the thing.

10,329. Did you mean to substitute it for the clubs, or would you have it supported by contributions in the general way ?—I had no idea of its being substituted for the clubs; I meant it to be supplemental to the clubs.

10,330. Would you have it supported by contributions from the men themselves, in the same way that the clubs are, or would you have it supported as infirmaries are supported ?—I did not contemplate that, but something of that sort might be possible: Whenever it has passed through my mind, which it has done very cursorily, I have thought that contributions from the mines and from benevolent individuals might be given to it.

10,331. But not from the miners themselves ?—I never thought of that. I may state that I believe that the quarter part of the population of Camborne live in houses which are the property of labouring miners.

10,332. Do you mean leasehold houses ?—Yes; I think that there are 800 houses in this town the property of labouring men, and almost entirely of labouring miners, which they have built themselves, and which they have for three lives. I am told that the aggregate amount of house property belonging to labouring miners in Camborne exceeds 50,000*l.*

10,333. You consider that an evidence of their prudent habits ?—Of their prudent habits, and of their temperate, orderly, and good conduct.

10,334. Do you think that miners are more in the

CAMBORNE.

G. Smith, Esq., LL.D.

7 August 1862.

habit of living in their own houses now than they were 30 years ago ?—Yes, beyond all comparison.

10,335. And that is an evidence of their improved habits, and their increasing prudence and foresight ? —Yes.

10,336. (*Chairman.*) What is the cost of building one of those houses ?—From 50*l.* to 80*l.*

10,337. Do they borrow a part of the money to build ?—Sometimes, but seldom.

10,338. (*Mr. St. Aubyn.*) What would each miner pay on his house as the ground rent ?—4*s.* or 5*s.* ; 1*s.* a lace.

10,339. (*Mr. Kendall.*) Have all those houses gardens ?—Almost all of them.

10,340. What is the extent of the gardens ; how many yards ?—From five to ten laces. A lace is 18 feet square.

10,341. (*Mr. St. Aubyn.*) Do you find that the men not only take a lease of houses on lives where the house is already built, but that they build houses themselves on waste land ?—Almost all these houses have been built by the miners.

10,342. Where do they get the money ? by mortgage partly ?—Not extensively. The way is this : The fluctuations in miners' wages are such as to give any prudent, good miner, once or twice in his lifetime, at least an opportunity of getting 40*l.* or 50*l.* as a start in a month or two.

10,343. (*Chaiman.*) You allude to tributors ?—I allude to tributors. The only difference is, where a man has a wife who will manage without going deeply in debt. If they are deeply in debt, every one of those starts is swallowed up. If they have managed to live without getting into debt when they get this start, the first thing they do is to build a house.

10,344. (*Mr. Kendall.*) Almost every active and clever miner, if he is prudent, becomes a tributor ?—Most certainly.

10,345. And every tributor, if he is a prudent man, and has a fair chance, has in his lifetime one or two chances of making a start, coming into a batch of ore, and making large wages ?—Yes.

10,346. And he builds a cottage entirely with his own money, or with money which he borrows ?—Just so.

10,347. (*Chairman.*) Do you mean that every miner, or even the majority of miners, are tributors ? —I should question whether the majority of miners were not tributors at some part of their lifetime.

10,348. (*Mr. Davey.*) They were so before emigration, but not since ?—Perhaps not.

10,349. (*Chairman.*) At present are a majority of the men tributors or tutwork-men ?—I should think that the majority are not tributors now.

10,350. A tutwork-man has not the same chance as a tributor ?—He has no chance of these starts.

10,351. (*Mr. Kendall.*) Latterly, in consequence of these starts, the mine agents have become more cautious, and they set the men to stope, instead of tribute ?—Yes.

10,352. (*Mr. St. Aubyn.*) What do you suppose is the number of working miners now living in Camborne, at a rough estimation ?—I can scarcely say. There are 800 labouring men who have cottages, and by far the greater number of them are miners.

10,353. (*Chairman.*) We have been told that the men shift very much from one mine to another ; is it your opinion that that is the case ?—They do, from one mine to another, although I do not know that that is the case to any great extent. Where a mining district fails, as some have done, and another becomes prosperous, of course the men have to remove.

10,354. But otherwise you do not think that a man who has a house of his own, or which he has furnished, would be willing to leave and take another ?—I do not think that they are accustomed to peregrinate.

10,354*a*. We have been told that the average earnings of the men are from 3*l.* to 3*l.* 10*s.* a month, but in an average some must earn a great deal more and some much less. Do you know what are the lowest earnings of the men ?—I do not. There is a vast difference in the men ; some men are really not worth 10*s.* a week ; sometimes the tributors work for nothing.

10,355. In the average wages are tributors and tut workmen included ?—When people talk about an average, they should explain their own terms. I have sometimes great jealousy about averages. I do not know what is included in them.

10,356. You would not take that as a guide as to the earnings of the men ?—If any one told me that the men in a certain mine averaged so much, it would go for nothing with me, unless I saw how it was made up.

10,357. (*Mr. Holland.*) When tributors get a start, is it common with them to waste their money, or are they generally prudent ?—It is not at all common for them to squander away the money ; it is a very rare thing ; they generally get a house of their own.

The witness withdrew.

Trevu, Camborne,
28th Jan., 1863.

My Lord,

Since giving my evidence before your Lordship and the other members of the Mines Commission, I have been led to inquire into the opinions and feelings of the miners on the manner of appointing the mine surgeons, and extent to which they are satisfied with the existing arrangements in use for that purpose.

And from careful and extensive inquiry, I find that I was much mistaken in the evidence I then gave on this subject. Althongh the men but seldom loudly complain, and are not forward, for obvious reasons, to speak on the subject, I am convinced that there is among them an extensive and deep-seated dissatisfaction with the manner of these appointments, and not unfrequently with the professional men who are so appointed.

I have now no doubt whatever that any measure which would give every man the free choice of a surgeon in any case of accident or illness, would be hailed by them as a great boon.

I have the honour to be,
Your Lordship's very obedient servant,
(Signed) GEORGE SMITH.

The Right Honble.
Lord Kinnaird, K.T.
&c., &c., &c.

Captain EDWARD RICHARDS examined.

Capt. E. Richards.

10,358. (*Chairman.*) What is the name of your mine ?—Great Wheal Busy.

10,359. I believe you have sent in a return of the number of men ?—Yes.

10,360. When had you a boiler accident ?—I do not know the exact time, but I think about October last.

10,361. In the course of the last two years there were three other explosions ?—Yes.

10,362. And you attribute that to the water, do you not ?—Yes, the foulness of the water. I think that the last was from the neglect of the engine man ; the man in charge. I think that two of them may be attributed to the men in charge ; what we call the engine man.

10,363. Was not it from not attending to the stopcocks ?—Yes ; to the gauge cock.

10,364. (*Mr. Holland.*) A neglect of the feed ?—Yes, we thought so.

10,365. (*Chairman.*) Have you two gauge cocks ? —Yes, to each boiler.

10,366. Have you any water indicator ?—Yes.

10,367. (*Mr. Holland.*) A glass gauge ?—Yes, inside.

10,368. To show the level of the water ?—Yes.

10,369. (*Chairman.*) In the other case you think

that the water had to do with the explosion ?—I am not prepared to say; it was heat a good deal. This is a piece of the boiler plate (*producing the same*), which was deeply honey-combed, more than half of the metal being dissolved away in parts.

10,370. How long do you suppose that boiler had been in operation?—I am not prepared to say; but it will be like that in three months in some cases.

10,371. (*Mr. Holland.*) How thick was this plate, to begin with?—Half an inch, I think; some of them are five-eighths, and some are half-inch plates.

10,372. Is this the top plate of the internal flue? —No; the side plate.

10,373. (*Chairman.*) How often do you examine your boilers?—We examine them very frequently; once in a month or less than that.

10,374. (*Mr. Holland.*) It blistered and blew out? —Yes.

10,375. (*Mr. Kendall.*) What destroyed this plate? —The foul water.

10,376. (*Mr Holland.*) Was it a coppery water?— Yes; there was a good deal of acid in it.

10,377. (*Mr. St. Aubyn.*) At last the plate got so weak that it blew out?—We think that it was blown out from the neglect of the man in charge of the boiler. This one was what we call cleansed the following day.

10,378. (*Chairman.*) Have you ever had any analysis made of the water?—Yes. We are now about to erect a little engine to pump up pure water off from the boundary of our set. We commenced the engine-house a week since.

10,379. You have had the water analysed?—Yes; it was very impure.

10,380. (*Mr. Holland.*) What impurity was there? —The acid of copper.

10,381. Have you a copy of that analysis?—Yes.

10,382. Can you furnish us with it?—Yes, I think so.

10,383. (*Chairman.*) If it were the acid of copper, might not such water used for boilers produce more or less the same effect?—The water in some mines is very much worse than in others. Our water underground at the 100th fathom level will cut off a half-inch iron in three or four weeks with a drop falling on it. We hope to prevent this now, and to have pure water coming into the boilers. We hope to get it in five weeks from this time.

The witness withdrew.

Mr. PHILIP VINCENT examined.

Mr. P. Vincent

10,384. (*Chairman.*) I believe you are surgeon to several mines in the neighbourhood?—Yes.

10,385. Do you know the number of men at the several mines of which you have charge?—I cannot tell exactly, but I am surgeon to rather more than 30 mines.

10,386. Have you more men on the sick list in winter than in summer?—I have more about the spring and the autumn generally.

10,387. Can you state anything like the number of miners in the course of the year who come under your care, not from accidents?—No; I am not in the habit of keeping a list of miners.

10,388. You do not keep any register of the cases? —No.

10,389. Have you ever had a post mortem examination of a miner?—Yes.

10,390. How long have you acted as a mine surgeon?—I have been brought up to it from my birth, and my father before me. I have been with him from the first.

10,391. Have you had more than one post mortem examination of a miner?—Yes, several; but not more than one for the miners' disease; it is a very rare thing that we can get one here at all.

10,392. Will you describe to the Commissioners what you observed on the occasion of the post mortem examination for the miners' disease?—On making the post mortem examination I found that the lungs were extensively diseased; indeed there were deposits in the lung of a substance which on taking it between my fingers presented the appearance of very fine powder made into small lumps, and in this powder there was a gritty substance which had the appearance of fine gravel; it looked very much like it. I did not analyse it, because I was satisfied in my own mind what it was, and I found several of the deposits in the lung.

10,393. (*Mr. Holland.*) In the air cells?—Yes. It appeared to me in one or two places where these deposits took place that there was pus forming around this, and there was a slight inflammatory action around, which had all the appearance as if this foreign deposit had been the means of producing some inflammatory action, and then of sending the miner into consumption. That was one case in particular, which was a very interesting one. An assistant of mine took notes of it, but he left me, and unfortunately took away the notes. He went to Australia, and what has become of them I do not know.

10,394. What was the age of that miner?—About 45.

10,395. (*Chairman.*) Had he been under your charge for any considerable time?—For some time.

10,396. How long had he been off work at the time when he died?—I think that he had not worked for nearly eight months.

10,397. (*Mr. Holland.*) How long do you think that he had been ill?—He had been ill for some time, complaining.

10,398. For several years?—Not several years, but for some very considerable length of time; he had been complaining about a year and a half or two years.

10,399. (*Chairman.*) Have you had much experience in treating miners' disease?—Yes, I have had a great number of cases.

10,400. (*Mr. Holland.*) In the case which you have mentioned was there any contraction or thickening of the bronchial tubes?—There was thickening.

10,401. Did it amount to contraction?—Yes.

10,402. Was the deposit general over the lungs?— Chiefly on the upper part of the lungs.

10,403. Was there any distinct tubercular deposit? —No.

10,404. Do you think that there is a distinct difference between miners' consumption and phthisis? —Yes, certainly; there is not the slightest doubt about it. I think that very often where a person is at all subject to phthisis, and where it is hereditary, when he works underground it is sooner or later called into action. We very often find that, and we very often find that if the miners get bronchitis, it throws them into this miners' affection.

10,405. Does the miners' disease generally begin with bronchitis or something like it?—Yes, very commonly. There is one case where I told the man to come here this morning, where it has commenced with bronchitis, and it is a very good case indeed.

10,406. Is it a well-marked case of miners' consumption?—Yes. I do not think that his lungs are extensively diseased at present, but if he continues to work undergronnd he will most decidedly go into that disease.

10,407. Have you practised in any other district than this?—I have been house surgeon in an hospital in London.

10,408. As a medical practitioner?—No. I was for some time assistant under Dr. Walsh at the University, and there I have seen some cases.

10,409. Do you think that the miners are less liable or as much liable to true phthisis as other workmen?— Certainly; in Cornwall we get an immense quantity of true phthisis.

10,410. As much among miners as among others, in your opinion?—I should think so.

10,411. The proportion of deaths from lung diseases

CAMBORNE.
Mr. P. Vincent.
7 August 1862.

is rather less among young men in Cornwall than in other parts of the country?—Yes. The Cornish miner does not suffer for some time; he is a healthy, strong young man, and you could not pick stronger men for a regiment of soldiers, but by working under ground they very quickly take on old age. I have remarked numbers of young men in this town who have become old men very quickly.

10,412. At about what age?—From 30 to 40. We always calculate that a miner is 10 years older than an agriculturist.

10,413. You think that that is a correct observation?—A very correct observation.

10,414. (*Mr. St. Aubyn.*) At what time of life?—Between 30 and 40 is the time when they begin to show signs of age.

10,415. (*Mr. Holland.*) Till then are they very healthy men?—Generally very healthy men. They are a class of fine developed young men.

10,416. In the miners' complaint do you observe that there is more difficulty of breathing early in the disease than in phthisis?—Yes; and we find that they expectorate a lot of black stuff, mucus, and which has all the appearance as if they had been inhaling some carbonaceous matter, as you very often see a person in the London fogs in the November month.

10,417. They have been inhaling carbonaceous matter, have they not?—Yes.

10,418. Is that what makes it black?—Yes.

10,419. If they have been some time out of the mine, do they cease to spit up black stuff?—Yes, invariably. Directly we get a man who is at all affected with anything in the shape of miners' disease, I always recommend him to get a place on the surface.

10,420. Does he then soon lose the black spit?—He very soon loses that, and recovers, and lasts for years, if he does not go back again under ground. We find a very great difference in the different mines where they work. If they work in granite mines we find that they are more prone to the disease in the cold granite mines than they are in the common killas.

10,421. Is it possible that that may be because there is more blasting in granite mines than in killas?—No; I think it is because there is more cold air. Very often, after working hard, they sit down to take some refreshment, and sit on a cold stone, and the draught going through, just to cool them as they take it, is the very thing which does the mischief.

10,422. Do you think that the bronchitis is often the consequence of repeated slight colds?—I think so, and that it arises from the irritation of swallowing the dust and the powder smoke and the candle smoke. When I speak of the air, of course the air underground is made up partly of candle smoke; the candles produce a great deal of smoke. Then there is the powder smoke after blasting which they inhale.

10,423. Some of the men have complained that the candle smoke is very irritating to them; have you any remarks to make upon that?—In miners' houses, where I have found some of the candles being burnt, it is certainly very irritating; it produces almost a smother in the room.

10,424. Have you noticed that hæmoptysis is more rare in miners' consumption than in common consumption?—Very much more so. We do not get hæmoptysis to anything like the extent in miners' consumption that we do in the ordinary cases of phthisis.

10,425. The sound of large cavities in the lungs is very rare, I am told?—Yes.

10,426. Is not the progress of miners' consumption very much slower than of phthisis?—Yes; they go on sometimes two or three years and sometimes longer.

10,427. Is the evidence of positive disease in the upper part of the chest as distinct in miners' consumption as it is in other consumption?—It is not generally quite so distinct, I think, as in ordinary phthisis.

10,428. In phthisis it is very much more frequent in the upper lobe?—Yes.

10,429. Is hectic decidedly more rare in miners' consumption than in common consumption?—You very seldom get it in the miners' consumption.

10,430. Is diarrhœa prevalent in miners' consumption?—They do not suffer a great deal from that.

10,131. Whereas they very often have it in the other consumption?—Yes.

10,432. Is there pain?—There is very little pain.

10,433. Decidedly less frequently than in the other consumption?—Yes.

10,434. You feel no doubt at all that miners' consumption is a distinct thing from phthisis?—I am sure of it.

10,435. And that is the common opinion of all well educated practitioners?—I believe so; I have never heard but one opinion.

10,436. It has been stated that a large proportion of miners' children die from mere debility within the first year of their existence, and it is added, "No one "who has not seen these miserable specimens of "humanity can have the slightest idea of their "diseased appearance, small, thin, and shrivelled, "with scarcely strength to cry. It seems sometimes "almost a crime to attempt to prolong their exis-"tence." Is that a correct description?—Certainly not; I do not think that there is a healthier lot of children in this country. Looking at the district which I take, which is very large, I do not think there is a more healthy lot of children in the world.

10,437. Is it not grossly incorrect?—Certainly, it is perfectly absurd.

10,438. It goes on, "This appearance can be ac-"counted for by no other cause than the debilitated "constitutions of the parents being entailed on the "children"?—I do not think that at all.

10,439. Are not a great proportion of miners' children born before their father's health is impaired?—Yes.

10,440. They marry early?—They marry very early.

10,441. And you said they do not generally become diseased till 30 or 35?—No. Many of them marry at 16 years of age.

10,442. If it were in consequence of the debilitated constitution of the parents, the younger children would have it, and the elder children not?—Yes. It strikes me very forcibly that the disease from which the miners suffer is not generally communicated to their children.

10,443. Do you mean you think it is a local and not a constitutional disease?—Certainly, and it does not affect the children.

10,444. Is it not a fact that the children af miners, say of this district, are remarkably free from scrofulous complaint?—They are very free from scrofula.

10,445. Can you compare them with the children of any other district which you know? Is there any difference in the healthfulness of agricultural children and of mining children?—I think not the slightest difference; if anything I think the miners' children are rather more healthy than the agriculturists' children.

10,446. Is there any extra difficulty in rearing miners' infants?—Not the slightest, you can rear them very easily.

10,447. If there be a large proportion of deaths of children in any district it must be because there are a greater number born?—Very often, when they get their infants bad, they will not send for a medical man, and they say, "Let the will of the Almighty work its "way." That is very common. They say, "An "infant of this size, a medical man cannot do much "for;" that is very common indeed. But I believe that our children are as healthy if not healthier than in any part of the West of England. You see them in Wendron parish, going about without any stockings or shoes, and the picture of health; they live in the wildest places.

10,448. (*Mr. Kendall.*) Have you ever been underground at all?—Never, but once.

10,449. You cannot speak from experience of the coldness of the water in the granite and killas mines?

—Only from tasting it. In the granite mines it is brilliant, sparkling, and icy cold, whereas the killas water is quite dirty.

10,450. With regard to the smoke in an end of a level, do you think that the miners injure themselves by rushing too rapidly to clear their holes?—In some mines I have heard they will not allow them to go in until the smoke is properly cleared; but if the agent is not close by they very often rush in for their own benefit, especially if they are tributers, so that they may raise as much ore as possible.

10,451. Their working in that air must be very injurious?—Certainly it is.

10,452. Taking the miners' houses and the agriculturists' houses, speaking of labourers, which do you think are the most comfortable?—The miners, decidedly.

10,453. Cleaner?—Much cleaner.

10,454. And much more comfortable?—Yes.

10,455. Who lives best; the miner or the agriculturist?—The miner is rather improvident about it; it is rather a feast and a fast with him. One day he will have his beefsteaks or his good living, and the next day he will have his porridge, and they live upon broth, as they call it, for some days afterwards, and they only throw in a bone or perhaps a little bit of pork to make the porridge; but the agriculturist generally gets his regular allowance from the farmer, and so it is regulated much better than it is with the miner.

10,456. But taking the whole run of the month, I suppose the miner tastes much more solid food?—Yes.

10,457. He has much more beef than the agriculturist?—Yes, a great deal more beef.

10,458. But he will have his Sunday dinner every fortnight?—He will have his Sunday dinner on the Saturday, especially on the pay day.

10,459. Whenever he can enjoy it, and has time, he will live well, even though at the expense of living badly for the res ofthe week?—Yes. I have known many a miner who has gone and sat down and drank his gallon or two of beer in an evening, and then they will not touch it again for the next month perhaps. I have said to them over and over again, "If you will "only just take your pint of beer a day for your "dinner, and be content with that, instead of taking so "much on your pay day, you will be a very much "better man at the end of 10 years than you will "if you live as at present."

10,460. Talking of the pay day, do they spend much of their money at the public-house?—Yes. I know one publican who does an immense deal in that way.

10,461. He prepares a large quantity of small change in order to accommodate the miners?—Yes; he gets a lot of silver.

10,462. According to the present mode of pay, the men having a large quantity of notes, I suppose they cannot divide their money without having some mode of change?—They very often go to the bank, and change their notes. The miners' bank make it, I believe, a point to change their own notes, so that if the men wish to do it, they can.

10,463. There are available means without going to the shop?—Yes.

10,464. If they go to the public-house, are they expected to drink anything out of a 5*l.* note?—Yes.

10,465. How much?—I cannot say; it depends upon the pair. A certain pair go to a public-house, and they will sit down there, and perhaps they cannot pay all this time, and they come next pay day, and pay then. A pair of men very often at the public-houses are looked upon just the same as I should look upon a patient. The publican says, "Such and such a pair come here," and they generally take a pretty good quantity. One could not go to a public-house, and get his note changed, unless he drank something.

10,466. (*Mr. Holland.*) Do you attribute any of the ill-health of the miners to the irregularity of their diet, of which you have spoken?—I think so. I think that if they lived regularly they would be very much better.

10,467. (*Mr. St. Aubyn.*) You have said, and I have heard it said before by two or three medical witnesses, that when you detect the first symptoms of the miners' complaint, if you can get them to take some occupation above ground they recover?—Yes.

10,468. And the expression used is that "they go on for years." Do you mean to say that when you take the thing in time you can make them as good and as strong as if they had never had the disease at all?—No; but it can be arrested in a measure, and very likely, if they worked upon the surface, they would live to a great age.

10,469. Supposing that you were examining for an insurance office, and that you had a man who had had the miners' disease to a small extent, and had come up, and had been working above ground a certain number of years, and was to all appearance well, should you consider his as good a life as if he never had been underground?—Certainly not.

10,470. Even if he never worked underground again?—No; I should be afraid of a deposit lodging about the lung, which sooner or later might develop itself.

10,471. Then it comes to this, that if a man ever is attacked by the symptoms of the miners' disease his must always be an uncertain life for the rest of his days, even if he leaves off his occupation?—Yes, I think so.

10,472. (*Chairman.*) You say that the air is made up from the candle smoke and the smoke of powder; do you know any other ingredient?—There is a certain damp sometimes in some mines, of which they complain.

10,473. What do you mean by damp?—It is a sort of heavy atmosphere; some gaseous matter. Very often the miners say, that although there is a draught going through a mine there is a very awkward damp which arises; they tell me so. I cannot say any further than that.

10,474. To your knowledge, there is no other ingredient injurious to health in that air?—Not to my knowledge.

10,475. I think you answered to Mr. Holland that you could not say that a man lived well who for many days was without meat, and yet ate a great quantity at other times?—No; regular living is certainly the best for any man. They always have a better dinner on Saturday or Sunday than on other days. On other days they feed badly; you cannot call it fasting. Their pay-day is only once a month, when the men feed too well; then they make up their other meals with porridge or pilchards, or something of that sort.

10,476. On the other days do you think that they have sufficient food, considering the work which they have to do in the mines?—I think it would be better if they had more beef or more meat.

10,477. (*Mr. Holland.*) If they distributed their earnings better through the month they would be healthier men?—Yes.

10,478. (*Chairman.*) Do you think that a man with a large family could do that upon his earnings?—Yes. When my father came here to practise there were only 700 inhabitants in this town; we are now 9,000, and the houses are chiefly built by the miners themselves; they are owners of their own houses, so that if their gettings were such as not to allow them sufficient meat they could not build their houses.

10,479. Do you know how much a house costs?—The price is generally from 50*l.* to 60*l.*

10,480. Is that built out of their own earnings, or do they borrow money?—Sometimes it is built by the lord, and the lord sells them the house, and I think they pay for it by instalments; but you will very often find that they pay it out of their own money.

10,481. So that the fact of a man having a house does not show that the money represents his regular earnings?—No.

10,482. We have been informed that the houses are built on the occasion of the men getting a good pitch?

CAMBORNE.

Mr. P. Vincent.

7 August 1862.

—It used to be the case, but it is very seldom the case now. You now scarcely ever hear of a start among the miners.

10,483. (*Mr. Holland.*) Why?—I think that the agents are pretty wide awake now.

10,484. (*Chairman.*) Therefore, although a man may have a house of his own, it does not follow that he has such an amount of wages by the week as to allow him to live well or equal to the work which he has to do?—No, it does not follow.

10,485. When a miner is off work from illness, and is in your hands, what means of support has he?—Sometimes they get into clubs, but not into mine clubs; the mine clubs do not grant it. In many mines, if the clubs are pretty well off, they are very kind to them; they are so in many mines with which I am concerned. But if the club is in debt they cannot afford to do much.

10,486. In that case, what is the men's resource for obtaining nourishment?—They generally have what they call miners' clubs.

10,487. (*Mr. Holland.*) Provident clubs?—Provident clubs.

10,488. (*Chairman.*) But I suppose that in your experience there are many who do not belong to such clubs?—Yes; many have not a bed in their house; but I have noticed that they are chiefly men who have been in the habit of drinking a great deal, and spending their money as they get it.

10,489. Many, I suppose, would have a better chance of recovery if there were any means of getting better food?—Yes.

10,490. And many, I suppose, require to be assisted?—Yes.

10,491. Do they apply to the union?—Yes; I am surgeon to the union as well, so that I know about them.

10,492. Are there many miners who are not permanently on the club who get assistance from the union?—No; very few. They do not like the union very well. Their names are published on every quarterly list, and a miner does not like to see his name up, although some would, I think, be everlastingly on the union.

10,493. But if a man was only off for a temporary illness he would rather not apply to the union?—In many cases.

10,494. (*Mr. Kendall.*) You know what the miners' wages are upon the average here, generally speaking?—They vary in some mines; in some of the mines I know them. I think I can tell you pretty well.

10,495. From your knowledge of their earnings, do you think that a miner earns money enough to give him that food which his hard labour requires each day, provided that he well regulates that money?—I should think so. If they got half as much again I do not think they would live a bit better than at present.

10,496. Your idea is that a miner is an improvident man?—I think, generally speaking, he is rather an improvident man.

10,497. That though he will now and then build his house out of certain gettings, yet amongst them there are a great many very improvident men.?—Certainly.

10,498. Taking a miner's wages, and taking into consideration the hard work which he has, if he regulated the expenditure of that money, and did not one day feast and the other day fast, he would make quite enough to supply him, even if he had a family, with what he wants?—I think so. Many miners work out of corps, and if they are badly off they might get work, but they will not do a couple of hours' work in the course of the day for you in your garden or your field.

10,499. Out of the 24 hours they never work more than 8?—Very seldom.

10,500. So that they have 16 hours for sleep and play or rest?—Yes.

10,501. You can very seldom get them to give any part of that time to extra labour?—Not one in three hundred will do it.

10,502. (*Chairman.*) You have stated that the men work for eight hours; does that include the time of their going to work, the time of going down, the time of coming up, and the time of changing and going home?—Yes; it includes the whole of it. They are generally expected to go down, for instance, at 2 o'clock; then from their candles they can tell what time it is, and when they should be up again.

10,503. But a man must take so much time to go to his work, and so much time to come back?—The time from his house to the mine is not calculated.

10,504. He is only eight hours underground?—He is only eight hours underground.

10,505. (*Mr. Kendall.*) Are their residences generally near the mines, or not?—I am sorry to say that a large number of them now are from four to five miles away from some of the mines.

10,506. (*Chairman.*) I suppose that in consequence of their building their own houses they very often live at a distance from the mine?—When they take a mine at a distance from their house, they can get a bit of land, where they can keep a cow or two, which is a very important thing where they have a family. If they were to come to live in the town, the houses would be very much more expensive, and they would have no land.

10,507.—Therefore you cannot say that they have all the rest of the time for play or extra work beyond the eight hours that they are below?—No, not in those cases.

10,508. Do you think that an average rate of wages is any real criterion of what each individual man earns, considering that many of these men are tributers, earning *5l.* or *6l.*?—I am not, of course, the agent of a mine, but I should think that a tutwork man gets from *2l.* 10*s.* to *3l.* a month regularly. We generally find that the tutwork men are the men on the whole who save most money, and their families are on the whole better off; they get more regular earnings; but a tributer will go on sometimes for three, four, and five months, and then he will leave the mine, perhaps in debt.

10,509. So that you think that a tutwork man earning from *50s.* to *3l.* is better off?—I think so, but I am not prepared to state that as a fact.

10,510. (*Mr. St. Aubyn.*) Should you say that the majority of those men who build and occupy their own houses here were tutwork men or tributers?—I should say that the majority of them were tutwork men. I have known a case where tributors, even since I have been in practice, took up as much as *900l.* in two months; but that is the only case that I have ever known here. My father, when he was alive, knew a great number of those cases, but you do not hear of them now.

10,511. Should you say that as a class the tutwork men or the tributers were of the most provident habits?—The tutwork men.

10,512. (*Mr. Holland.*) Is it your experience that there is a great deal of dyspepsia among the miners?—The miners' disease generally commences with a sinking in the stomach; they complain of that. Palpitation of the heart is another symptom of which they complain.

10,513. Do you think that that is symptomatic?—I think it is symptomatic with the stomach; there are many cases of that sort now.

10,514. Is there much disease of the heart, accompanied by distinct physical signs?—No, I should not say that there is.

10,515. Is acute rheumatism common?—Yes, we see a good many cases of it.

10,516. Is there a good deal of disease of the heart, following acute rheumatism?—No.

10,517. Do you think that the climbing of the ladders has much effect in producing disease of the heart?—I should very much doubt it.

10,518. Have you noticed any remarkable peculiarity in the miner's heart?—They have generally large hearts, but not often marked by any disease. I believe

that in miners who begin young the heart grows in proportion to the work which it has to perform, and thereby escapes disease until the lungs become affected.

CHARLES FOX, Esq., examined.

10,519. (*Chairman.*) You have for a long time taken an interest in miners, and are likewise connected with mines?—Yes.

10,520. Will you be kind enough to mention to the Commission any points to which you think they should turn their attention, particularly with reference to the sanitary condition of the mines?—As I have often stated in public and in private, we are entirely deficient in any statistics on the subject. We do not know the extent of the evil, either as it regards accidents, or disease, or death amongst the miners. It is only here and there that you glean some statistics on the point, and by the labour of individuals. We have no record, as far as I know, of the accidents which occur, whether fatal or otherwise, nor any account to be depended upon of the mortality amongst the miners as a class—no safe record. Great pains have been taken in the different parishes, but after all it is like groping in the dark to a certain extent. I regret that our medical men have kept no accessible record of the cases in the mines which have been specially under their care. We go to the union house, and there we see a record of all the cases which are under the care of the medical man; how many weeks a man has been ill, and what the nature of his disease was; and, although he does not keep any record of the medicines, he tells you when he orders extra diet; but we have nothing analagous to that in our mines, and I should conceive that there would be no practical difficulty in having such a record kept. I have gone further, and urgently recommended that a register should be kept of every person employed in the mines, both as to their ages, and the circumstances under which they were living, especially if at a distance from the mines. At such a place as Camborne this applies in part only, as the residences of the population are in the midst of the mines. Sometimes the miners have to go a distance of three, and four, and even five miles, although that is much less the case now than it formerly was. I do not know whether, amongst the inquiries of the Commissioners, they have obtained any evidence of miners as to their suffering from the length of a core and eight hours shift or not. I think it would be an advantage to the miners if there was a medical inspection, more or less periodically, of those working underground, in order that the commencement of disease might be detected before it becomes illness. It might be thought needless, but I think that that system has told eminently well in the military service.

10,521. Do you consider that the subject of ventilation is important to inquire into?—That, I think, is a main point.

10,522. Could you give the Commissioners any suggestions as to how they should obtain information upon that point?—It can only be ascertained by inspection and examination.

10,523. Have you ever made any inquiries as to the state of the air in the mines?—I have experienced it myself in places, especially where in a level the stuff has been heaped up, but not by analysis, except as it has been reported to our Polytechnic Society.

10,524. (*Mr. Holland.*) Are you referring to specimens of the air taken from close ends?—Yes; my idea is that where men are working for six hours, where the air is bad, there are cases where it would be better to make a shift, and make it only four. But after all that must be left to the local agent; it is a mere general expression of opinion on my part.

10,525. (*Chairman*) Have you ever seen any means tried, or have you known of any being tried, effectually to get rid of the poor air in close ends?—Yes; there are many mines in which the miners could not work at all without the air machines.

10,526. Do you think that they effectually get rid of the poor air?—Yes; in some instances they do it effectually, and in others they only do it partially.

10,527. It has been stated in evidence over and over again, that sometimes one shaft is a downcast and another is an upcast, and that that depends upon the wind. Have you ever obtained any information, or had any experiments made, in order to ascertain whether the air in a mine is not constantly travelling through the different levels, and without coming up?—No; but I have no doubt that it is often the case.

10,528. (*Mr. Holland.*) That is, that it circulates in the mine, and not through it?—Yes; the great difficulty is as to the powder smoke. Then, with regard to the expenditure of muscular power, before the man-engine was introduced, I found in the Consolidated mines, after multiplying the number of men by the depth from the surface of each level, and reducing the whole to unity, that it amounted to an ascent many times as great as that of the Himalayas.

10,529. Do you consider the man-engine of great importance and utility to the miners?—It saves their muscular labour, and the hurried action of the heart and lungs.

10,530. Is there any other point upon which you can give the Commission any information?—I think not.

10,531. (*Mr Holland.*) Have you had any reason for altering the calculation that you made when the man-engine was first proposed as to the average loss of labour in climbing the ladders?—I think it was rather made by the committee than by myself. I was on the committee. I do not remember what it was.

10,532. (*Mr. St. Aubyn.*) Can you furnish the Commission with any statistical information as to the number of men who were receiving allowances from the club in any mine, before the introduction of the man-engine, as compared with the subsequent period?—No; I should like very much to obtain it, and I have tried to get it, but in vain.

10,533. I believe that you offered a premium for a machine?—Yes; I offered a premium for a man-engine. I said it was to be on certain commercial conditions, namely, that every man must be lifted 100 fathoms at a penny per 100 fathoms, including the tallow and the expense of working the engine, and 10 per cent. on its original cost for wear and tear; and the committee at once decided, on the models that were produced, that they came within my conditions. Then, with regard to striking with the borer, and most often in a narrow space, a hammer is lifted which sometimes weighs 10 lbs. and sometimes 12 lbs. 6 or 7 times in a minute, and that is injurious to the heart.

10,534. In some districts do not the men work single handed, driving the borer with one hand?—Not to my own knowledge; but I do not doubt its being done.

10,535. Have you had any experience with regard to blasting the holes, and the accidents caused by it?—No; only that certainly many of them might be avoided, there is no doubt about that.

10,536. You think that if proper precautions were taken by the managers and agents those accidents might be diminished?—I do not think that the managers and agents can do much more than they have done; it is to be done by the men themselves. I think that the major part of the accidents arise from the miners going too suddenly to a hole, thinking that the fuze has gone off.

10,537. Where there has been perhaps an imperfect fuze?—I do not know anything about that.

10,538. (*Mr. Holland.*) With respect to tamping; do not you think that it would be a great advantage to substitute a bronze for an iron tamping tool?—Yes, that has always been acknowledged; that was Sir Humphrey Davy's introduction; that would be a very valuable precaution, and it would avoid many of those accidents which arise.

10,539. Will you be so good as to describe the

CAMBORNE.

C. Fox, Esq.

7 August 1862.

tamping wedge?—There is a wedge with a sharp edge, the cylindrical end resting upon the powder in this way (*describing the same by a sketch*); the effect is that this wedge is driven up, and immediately expands the fork of a cleft stick above it; that has been done successfully in many places; but the miners do not like the trouble of it; the cost of it is very trifling.

10,540. (*Chairman.*) Could that be applied to a cartridge?—Yes.

(*For a sketch of this invention refer to the Transaction of the Polytechnic Society.*)

10,541. Do you suppose that two pieces of ore or two pieces of the country striking together would produce fire that would ignite powder?—Yes, they may, under certain circumstances, if you find a very hard metallic surface.

10,542. Would you recommend gun cotton to be used?—I wish that it may be tried, where abundant powder smoke accumulates; it might be made as wanted or preserved in a glassy envelope (invented in Germany, as I am told).

The witness withdrew.

MR. THOMAS HUTCHINSON examined.

Mr. T. Hutchinson.

10,543. (*Chairman.*) You have, I believe, charge of a good many mines?—Yes.

10,544. Has your attention been directed particularly to the miners' disease?—It has been directed to the illness of miners.

10,545. Have you ever had an opportunity of making post mortem examinations?—Not in any case of miners' affections; not in disease of the lungs.

10,546. Do you keep any record of the cases that come before you?—I am Registrar of Births and Deaths, and I have a record in that way, of which I keep a copy to some extent.

10,547. But do you keep a record of the actual cases that come under your notice?—I have, of some.

10,548. You do not keep a record of all the cases?—No.

10,549. I suppose that a great many of the patients just come to you and go again?—Yes. If there have been any particularly interesting cases, bearing upon this subject, I have lately kept notes of them.

10,550. Are there any cases the particulars of which you would like to furnish to the Commission?—I have done so already, so far as I have been able to do so. I have no additional cases, beyond those to which the Commissioners have already had access.

10,551. (*Mr. Holland.*) I believe you are clearly of opinion that miners' consumption is distinct from common consumption?—That which passes under the name of miners' consumption is certainly not tubercular phthisis, at least a great number of cases that are registered for phthisis are not tubercular phthisis at all, but they are a combination of various complaints, bronchitis, emphysema, and disease of the heart, but they are registered under the head of phthisis, as it is a short term, and easily recorded. I expect that is the reason.

10,552. Is the absence of large cavities in miners' consumption a fact established?—I do not know that it could be thoroughly well established without post mortem examinations being made, but my general opinion is that there are not such large cavities.

10,553. The presence of which you can detect by the ear?—You do occasionally meet with cavities, when you find that there is a metallic tinkling, and such sounds are demonstrative of a cavity, but I think that the cavities are smaller than in tubercular phthisis.

10,554. Is hectic a symptom rather rare in miners' consumption?—I think it is less common in the fatal diseases among miners than in ordinary consumption.

10,555. Have they much spitting of blood?—Yes, but that is less frequent than in phthisis.

10,556. If persons who are seriously ill with miners' consumption can change their employment, and work on the surface, is the disease suspended?—I think that in a very early stage, when they have simply bronchitis, it would be relieved, but I do not think it would be in an advanced stage, or in the secondary stage, but in a very early stage it might be, when they first begin to complain.

10,557. The Commissioners have been informed that in an advanced stage of the disease a man may continue to work, and may live a long time?—A man could not work in an advanced stage of the disease.

10,558. When a man is unmistakeably ill from miners' consumption, and he can change his employment, is there not a fair chance of his living a good long while?—I do not know that.

10,559. Have you noticed that in miners' consumption the upper part of the chest is not more diseased than the rest?—I think that in diseases of the lungs, from which the miners frequently suffer, it is more often at the lower than at the upper part.

10,560. Do you think you can rely upon that?—Yes, quite so.

10,561. That is just the reverse of phthisis, is it not?—Yes.

10,562. Do you think that the powder smoke is a serious cause of irritation to the miners?—Yes; I think there is no doubt of it.

10,563. Are the miners very liable to catch cold?—I think they are, being more exposed to changes of temperature, to which they are liable from the nature of their occupation.

10,564. It has been suggested that disease is very frequently produced by a succession of colds, not any of them amounting to actual illness, but from a constant irritation of the air passages; do you agree in that opinion?—I do not think that that one cause is sufficient to account for it, as I believe that there are many; there is the powder smoke, the dust, the frequent colds, the climbing, and other violent exercise.

10,565. Do you think the dust is a frequent cause of injury to them?—Yes, in many cases; the dust and the powder-smoke, and the frequent colds which they catch; indeed there are many causes; it is not any single cause.

10,566. Have you observed that the miners are particularly subject to dyspepsia?—Yes, I think they are.

10,567. Is the water-brash common among them?—Yes, and I think that is more from their diet than from anything else; from the pasties, and the indigestible food which they eat.

10,568. They say that their appetites are temporarily destroyed when working in hot air; do you think that is so?—Yes, I think there is no doubt of it. I frequently find them complain of loss of appetite when working in hot places.

10,569. Will not that produce weakness of digestion afterwards?—Yes, no doubt of it; but I think it is as much attributable to their food.

10,570. What fault have you to find with their food?—They take hoggan down with them, and that is very heavy food; it is a solid mass of flour, mixed with water, and baked without any leavening at all.

10,571. It is like a lump of heavy pie crust, but even heavier?—Yes.

10,572. Why do they prefer that?—I think because it is more convenient to carry underground.

10,573. Do you think that miners are more liable to rheumatism than other labourers?—No, I think not.

10,574. Have you noticed that they suffer from distinct heart disease, frequently?—Yes; it is very common.

10,575. In what form?—Dilatation.

10,576. Hypertrophy?—Yes; valvular disease is not so common.

10,577. Is rheumatic disease of the heart rare amongst miners?—It is not common.

10,578. Have you noticed symptoms of dilatation of the heart without valvular disease?—Yes, very frequently; it is very common.

10,579. Do you attribute the disease of the heart chiefly to climbing?—Yes; I think it is chiefly attributable to over exertion in all their labour as well as in climbing, for instance, in beating the borer.

20,580. To which do you think it is most ascribable?—It is difficult to say, but they both contribute.

10,581. Have you seen any great difference in the frequency of dilatation of the heart among those miners who climb up by ladders and those who come up by the man-engine?—I do not think there has been sufficient time yet to verify that; the man-engine has not been introduced sufficiently long here to test it.

10,582. The children of miners have been described as being born very weakly, and hardly fit to rear; do you agree in that?—No.

10,583. Is not the contrary of it the truth?—Yes; I think that they are naturally very strong.

10,584. Is there any unusual difficulty in rearing the infants of miners?—Not at all. There is an ignorance amongst parents as to the proper food to give them.

10,585. Do they begin to fail after they are weaned?—Yes. When theydo fail, I think it is then. When the children are older they get on better; but there is an ignorance of domestic economy among them. I think it is more from want of proper food after weaning than any other cause.

10,586. Are you sure that at birth the children of miners are quite as healthy as any other children?—Yes.

10,587. And remarkably healthy?—Yes.

10,588. Have you noticed scrofulous disease frequently, or is there an absence of it?—There is quite as great a freedom from scrofulous disease here as in any other neighbourhood, and perhaps more so.

10,589. Are not scrofulous diseases and glands in the neck very rare?—They are very rare; very uncommon.

10,590. Are not marasmus and tabes mesenterica very rare?—Yes.

10,591. (*Chairman.*) Have you any suggestions to make by which the causes from which miners suffer by working underground might be modified?—If the climbing up the ladders could be done away with it would be very advantageous; they evidently suffer from climbing, from want of ventilation, from the powder-smoke, and the dust. If the levels could be made wide, these and the edds better ventilated, and the climbing done away with, the condition of the miners would be much improved.

10,592. Do you think that they suffer from breathing a particularly bad air, or from a want of oxygen?—I think it is a want of oxygen, as far as I know.

10,593. Might there not be an excess of carbonic acid gas?—Yes, there might be, and it would produce the same effect.

10,594. Supposing there is an excess of carbonic acid gas beyond what was the product of combustion, would not that produce many of the effects described by the miners who suffer from working underground? Yes.

10,595. (*Mr. Holland.*) It has been stated in evidence that where candles burn freely the miners may suffer much from cold damp, without a deficiency of oxygen; have you heard of that?—Yes; I have heard many miners say that they suffer from cold damp where the candles burn freely.

10,596. (*Chairman.*) If there is an excess of carbonic acid gas, the test by the candle not burning could not be relied upon?—Not entirely, I think.

10,597. You are aware that the test to which they all resort is the burning of a candle?—Yes; no other test is used.

10,598. (*Mr. Holland.*) In the case of cold damp, that test would fail them?—Yes. The miners act wrongly as to one thing; if they do not feel sick, and they can eat their food, they keep on working, alhough they may have bronchitis, which they very often have; and they will go on for a month, or two months very often, with cough and wheezing, and considerable difficulty of breathing, indicative of serious chest affections, provided they do not feel weak and ill, or suffer pain.

10,599. Are their stomachs often very much affected?—Very frequently.

10,600. Might that arise from inhaling carbonic acid gas?—Yes; no doubt of it.

10,601. Some of the miners have stated that the first effect which they have experienced has been a weakness in the calves of the legs and shaking in the limbs, before the candle indicated anything?—I have not heard them describe a shaking of the limbs, but they all complain of weakness in the legs.

10,602. Do you think that is caused by poor air, or by cold damp, or by both?—It is difficult to say; perhaps by both. I find that in the last 531 deaths in Camborne, 45 are registered as from phthisis, 30 of those occurred among tin and copper miners, and 15 were the wifes and widows of copper miners.

10,603. (*Mr. Holland.*) There being twice as many among the males as among the females of the same?—Yes; the total number of deaths amongst tin and copper miners in the 531 was, from all causes, 55, and the deaths from phthisis amongst those were 30.

The witness withdrew.

JAMES JAGO, Esq., M.D., Oxon, examined.

10,604. (*Chairman*). You reside at Truro?—Yes.

10,605. You are, I believe, physician to the Infirmary, and also to the Truro Dispensary?—Yes.

10,606. In the course of your practice, have you had many cases of miners suffering from any ailments, other than accidents, brought under your notice?—In a certain stage of disease, many among the in-patients of the infirmary also; I see a good many who come as out-patients to the infirmary; and I may say especially to the dispensary, from certain parts.

10,607. When you say from certain parts, do you mean that they come in an advanced stage of disease?—When they think that they do not get cured at the mine, they often come as out-patients, if they live near enough, to one of these institutions.

10,608 Have you ever attended at a consultation with any of the mine doctors?—I have frequently had consultations with them; but, generally speaking, the working miner is not very well able to pay for consultations. I have had consultations in the cases of men who have retired from the mines, having acquired a little capital; but I do not go out into the country to attend consultations in the case of ordinary miners: they cannot afford it. They sometimes consult me at my own house by the wish of the mine doctor.

10,609. Mr. Vincent has stated that there was a case that you had watched with him, or to which he had called you in?—I have seen many cases with him, and possibly a case of a working miner, but I cannot call such a case to mind.

10,610. Have you seen enough of these cases to enable you to give a decided opinion as to the nature of the complaint called miners' disease?—I do not altogether recognize it so positively as I have seen it characterized. There is such a thing as miners' disease, in contra-distinction to consumption; and I mean to maintain that there is a peculiar affection of the bronchial tubes connected with bronchitis and sometimes emphysema, by which the miner becomes worn out, and becomes so weak that he ceases to come to the institutions which I belong to, to consult me, and I therefore really hardly know what then becomes of him. At the same time, I do see consumption in miners of all ages—actual consumption; but still there is such a

CAMBORNE.

J. Jago, Esq., M.D.

7 August 1862.

thing as a very weakening complaint of the nature of bronchitis. I do not think that it is always of that nature. I believe that many miners have inflammatory affections of the chest, although I rarely see an acute pneumonia and pleuritis case. Sometime ago, I had a case in Truro, in an acute stage. The man now lives here, and his name is Collins. That man, when he came under my care, was suffering from pericarditis.

10,611. (*Mr. Holland.*) Was it rheumatic?—No; there was no rheumatism connected with it whatever. On the subsidence of that attack of pericarditis, he had an attack of pleurisy on the left side; but he left the infirmary at the end of two months, well enough to go to work again after another two months' rest, and he worked for two months underground as well as he ever did in his life. Then he got some other acute affection, and came to the infirmary under Dr. Barham. I did not examine him: but he has consulted me again lately, and he is now in such a state that he has short breath, and he is perfectly unfit for mine work. A little while ago, he was very angry with me on account of a suggestion that I made—I thought that he might do some very light work aboveground. This man is in a state of what many might call miners' consumption. I mentioned it to Mr. Hutchinson, his mine doctor, as a case of the kind; it was a case of inflammatory disease. I have often examined miners who have had an impediment in their breathing; and I have often examined miners who have had the remains of pleurisy about them. I mean that on one side or the other they have had an attack of pleurisy. I attribute some of their failing health to these attacks.

10,612. Have you had an opportunity of making post mortem examinations in the cases of miners' consumption?—Never. I asked Mr. Hutchinson, about a year ago, for an opportunity. I said that I would come to this town at any time on purpose, and he promised to bear it mind.

10,613. Is it not most desirable for post mortem examinations to be made, to ascertain the exact nature of the disease?—Yes; and I think it is quite easy to obtain them by anybody living in the neighbourhood of the mines. I do not believe in the prejudices of the people, for I find that a medical man can persuade the relatives, if he likes, to allow post mortem examinations to be made.

10,614. Are they not made because surgeons have not time for them, or that they do not think them worth inquiring into?—Mine surgeons have little spare time, whilst many of them are prepossessed with the notion that miners have a repugnance to post mortems.

10,615. I believe you are not specially a miner's doctor?—No; but I have seen in the Truro Dispensary—from St. Agnes and Chacewater particularly, owing to the fact of some subscribers to the dispensary living there—a great many sick miners. I see them with various complaints; some with bronchitis, occasionally with black sputa, sometimes with other chest diseases. I have a young miner, aged 22, now under my care, who came from this neighbourhood, and that is a case of mitral valve disease of the heart; he suffers from want of breath.

10,616. Do you think that that was produced by working underground?—I do not know. He was put to work underground very early.

10,617. Do you think that going to work early underground would predispose to such disease?—I have no evidence to show that it would, but I should be very suspicious that it might.

10,618. (*Chairman.*) From your observations in the examination of miners, should you say that their illness was the effect of working in impure or poisonous air?—Looking at the anæmic and pasty colour of the miner, which is very peculiar, and other facts as to his breathing, and I have seen them come to me excessively weak, when I have been unable to detect any special cause to account for their want of breath and general weakness, excepting the mere absence of the red colour in their features; the unfavourable condition under which they work alone seem to me sufficient to account for the great deterioration in their strength, and very likely for their gradual decay, bringing on premature old age, and I think a loss of their vital power or force.

10,619. Do you mean by unfavourable conditions a want of light or air that is not vitiated?—I should say there was a want of both. I cannot discriminate between them; both combined might produce the effect; bronchitis might be produced by other causes.

10,620. I suppose a sudden change of temperature is bad?—Yes; going from one state of things to another.

10,621. Or ascending a great height by the ladders, and then having to go some distance to a changing house?—I think that quick cooling after such exertion might be one of the causes. I have observed, however, in the Truro Dispensary that we have a great number of shoemakers. I do not know the number afflicted with bronchitis. I always conclude, if I see a shoemaker enter the dispensary, that he has bronchitis. Why he should have it, unless there is anything about the wax that he uses to irritate the lungs, I do not know, but it is a fact; that a liability to bronchitis is not peculiar to miners. I should say that the shoemakers about Truro are more affected by bronchitis, although they do not die from it, than the miners.

10,622. Do you think it arises from the position in which the shoemaker works?—It may be so, but it is most striking, the number of that class who suffer from bronchitis; some of them are quite asthmatical with it.

10,623. Have you made any post mortem examinations of shoemakers?—No. The bargees on the river at Truro are very subject to bronchitis—from exposure, I should suppose.

10,624. What size is the infirmary at Truro?—I think we make up 64 beds.

10,625. Is the infirmary large enough for its district, do you think?—It is not large enough, since the railways have been opened. We are always full of late.

10,626. What number of cubical feet of space is allowed in proportion to the number of beds?—I cannot answer that question, although the space has been measured. The infirmary is not altogether well built.

10,627. (*Mr. Holland.*) Is the infirmary small in proportion to the number of its inmates?—The beds are too much crowded, to please me, while the old wards are not high enough.

10,628. I suppose there is no doubt that miners are specially liable to lung disease?—I have no doubt that they are. I always examine a miner's lungs, and expect to find some mischief there; if not consumption, something else, with which they seem to drag on for years.

10,629. Have you seen many miners suffering from distinct tubercular consumption?—I have seen a great many young miners, and several older ones so suffering.

10,630. Have you seen many miners with lung disease that was not tuberculous?—Yes.

10,631. A large proportion?—Yes.

10,632. Do you think it likely, from the miner's mode of life, that they will suffer from an unusual amount of bronchitis?—I think it is likely that they will.

10,633. You do not know that they do, from your own knowledge?—I am inclined to say that they do suffer from bronchitis more than the average of the labouring people. Special classes appear to me to suffer than they more, but they more than the average.

10,634. It has been stated in evidence that a very large proportion of the miners die from lung disease, which is called consumption, and includes all sorts of lingering disease, with cough and expectoration. Can you give any evidence as to what that disease generally is?—I instanced the case of Collins, to give you an idea of what kind of case might be registered as such a case. All such cases I think are so registered. There are a great many cases of pleurisy among miners,

and a great many cases of pneumonia, and a great many cases of bronchitis occur; emphysema and disease of the heart also occur, but not so frequently as many persons say they do. All these cases are attended with difficulty of breathing.

10,635. There are a great number of complications?—Yes.

10,636. Can you say whether a large proportion of these cases are bronchitis?—I should say that more or less bronchitis would be present, but perhaps at times I might consider emphysema to be the leading complaint. In certain of these cases I have been able to detect a considerable amount of emphysema in the lung.

10,637. A thickening of the lining membrane of the bronchial tubes has been mentioned as a very frequent circumstance; does that correspond with your observation?—I have never had an opportunity of examining the bronchial tubes. Still I find miners with black mucous expectoration, which may arise, for what I know, from what they breathe in the mines—carbonaceous matter, which had adhered to the lining membrane.

10,638. Do you think that that may arise from the smoke?—I suspect that such cases do occur, among others. I think that the lungs get irritated by breathing, very likely, dusty matter in the mines and the gunpowder smoke, and that these irritate the bronchial tubes, and, among other things, tend thus to damage the miner's health. These, combined, with the anæmic state they get into, from the peculiar conditions under which they breathe, certainly weaken the miner, and make him at last worth little as a man of work; but I have rarely had an opportunity of following these men to ascertain whether they die soon from such declining health.

10,639. Have you seen any cases of miners who have returned from abroad affected in any way?—I have seen men from Cuba and Columbia in South America; perhaps I have seen a dozen cases; and those men are remarkable for the extreme paleness of their complexions, having more the appearance of anæmic women than anything you commonly see in men. I have examined very carefully, as my own patients, at least seven or eight of these men, and I never could make up my mind that I could discover any organic disease whatever, except in one, and in that case I was not clear that he might not have had some enlargement of the spleen. This man laboured so much from want of breath that latterly he was scarcely able to crawl half a mile at a time. They may remain for years in very good condition, and not lose flesh. Their appetite remains good, and they rarely complain of anything, except palpitation of the heart and want of breath, with perhaps, like anæmic women, pain in the pit of the stomach after eating. They are without disease either in the heart or in the lungs. There is occasionally an anæmic bruit in the heart, but only occasionally. They are just for all the world like an anæmic patient. I have taken pains to inquire about these things, and I am satisfied that nobody coming home from Cuba or Columbia ever contracts this disease who has not worked underground. I have found such cases amenable to treatment, they being always benefited by iron, but very difficult to cure. I believe I may have turned out some three or four of them able to go to work again; but the majority of them cease to attend, when they get a little more colour in their faces from taking iron, and relapse into anæmics. I have also found that all the preparations of iron do not appear to act alike, the most successful being the sesqui-chloride of iron. In one instance I had a man from Cuba under my care for months; and he was troubled, in addition to the symptoms mentioned, with extreme constipation. I could do nothing with him until I added chlorate of potash to the sesqui-chloride of iron, when he at once commenced to have regular evacuations, and became rapidly well, and went to work, driving an engine.

10,640. (*Chairman.*) Did you ever examine their blood?—Yes, I have examined the blood of these patients.

10,641. Did you find any peculiar symptoms in the blood?—It is some years ago, and I thought that there was something peculiar in the form of the globules of the blood; but having made some examinations of the blood of perfectly healthy patients afterwards in different temperatures and degrees of dilution, I doubted whether I had seen anything from which I could draw a conclusion.

10,642. Do you think that the disease contracted by men working underground here has any resemblance to that which miners suffer from abroad?—I believe that the disease in question is peculiar to such climates; and could not be produced anywhere else.

10,643. (*Mr Holland.*) It is not an aggravation of the Cornish disease?—No.

10,644. Are the Cornish miners often anæmic?—Yes, they are, but nothing like in the same degree that the other men were to whom I have referred, and their faces have a muddier hue.

10,645. Is it likely that breathing air deficient in oxygen would alone be enough to excite bronchitis?—I have no knowledge of the fact.

10,646. (*Chairman.*) Would a person from breathing an impure atmosphere, the tone of the whole system being lowered, be more liable to bronchitis?—I could imagine that a man working in air insufficiently supplied with oxygen, might strain his lungs and make them emphysematous, and possibly irritate the lining membrane into inflammation.

10,647. (*Mr. Holland.*) If there is an excess of bronchial disease among the miners, and we know that they are exposed to violent alternations of temperature, and to breathing the irritating fumes of powder smoke and dust, would you not rather attribute it to those causes, than to a deficiency of oxygen or an excess of carbonic acid?—If there be an excess of bronchial disease I should be disposed to say so.

10,648. To what do you attribute the excess of emphysema among the miners, which you believe to exist?—I always theorize with reluctance; but with that proviso which you have put in the previous question, I should attribute so much excess as I may have admitted to their working in air insufficiently supplied with oxygen, and their thereby straining the lungs more than other persons would; and there is also this, that when they do get attacked with bronchitis the effect of the strain in coughing might have a tendency to produce emphysema, and in that way this would also be a consequence of bronchitis.

10,649. Do you think that climbing the ladders would account for emphysema fairly?—I have no knowledge that sailors become emphysematous from climbing ladders.

10,650. Have you frequently witnessed men just after they have come up a footway?—I have not often done so. I have not been present to see them at all in any medical capacity.

The witness then withdrew.

Mr. JOHN PERMEWAN examined.

10,651. (*Chairman.*) I believe you have charge of several mines in conjunction with Mr. Hitchins?—Yes.

10,652. Have you frequently had opportunities of observing cases of miners who have come to you suffering from ill-health?—Yes.

10,653. I believe you have had several cases lately?—Yes; we are constantly seeing them.

10,654. Are you of opinion that the complaints from which miners usually suffer present any special characteristics as compared with other persons?—I think they do. I think they suffer from a distinct disease; that is, distinct from phthisis.

10,655. In your experience, have you made any post-mortem examinations?—I have never had an opportunity of doing so. I cannot do it.

CAMBORNE.

Mr. J. Permewan.

7 August 1862.

10,656. Do you only judge from the symptoms ?—Only from an examination of the physical signs.

10,657. Have you formed any opinion as to the pathological condition of the patients ?—Yes. I think, in describing a case of miner's disease, that we have an opportunity of seeing it at the beginning. Very frequently a man comes complaining first of symptoms of indigestion and dyspepsia; that is the first symptom that we find, with headache and loss of appetite, and vomiting frequently ; throwing up his food. He also complains of pain over the epigastrium, and in a very short time he complains of his breath being short, and the heart beats irregularly ; there is palpitation. I think I might say that for the first three weeks or two months there is no cough ; but after that they have a short hacking cough, without any expectoration.

10,658. (*Mr. Holland.*) How long does that condition last ?—That is at various times ; it may go on ; it all depends upon the character of the man's work. If he is still working in the same place it will be for a very short time before expectoration will take place ; if he goes out of the place where he has been working, and is properly treated, and gets rest, he will get better in that stage.

10,659. (*Chairman.*) Have you ever known a case in which where a man has been shifted from the particular end in which he was working to another level a good effect has been produced ?—Yes, decidedly.

10,660. (*Mr. Holland.*) From changing to another level ?—Yes, there has been a decided change at once. We ask the miners how long they have been working at such a place ; they say three months perhaps, and then we say that they ought to get out of it, and they say, "We expect to hole in a fortnight." After that time, they go into purer air, they get on very well indeed, and it passes off entirely if they get into purer air. We find that these dead or poor places are generally in a winze or in a shaft.

10,661. Is the effect equally good, whether they change their place of work or not, provided the air be improved ?—Yes, I think so ; there is no doubt about it.

10,662. (*Chairman.*) Do you ever advise men to leave mining work altogether, and to go to the surface ?—Yes ; frequently that is our recommendation, if we see that they are able to do so. They ask us whether we think they had better do so, and we always recommend it, if possible.

10,663. Do the men who come to you in that state spit up a good deal of black sputa ?—Yes ; that is the first character of the expectoration ; it is frothy stuff, mixed up with black particles ; what it may be we cannot exactly say.

10,664. How long after leaving his work would a man continue to spit up that black stuff ?—I have known it for years, and I think I could point out to you two or three people now. I know one in particular, and I know that he has not worked underground for 10 or 15 years, and he has every characteristic symptom of the old miner ; he spits up now black expectoration. His name is John Cock.

10,665. (*Chairman.*) Suppose that he returned again to work in poor air, what would be the effect upon him ?—After a short time he would have an attack of pneumonia ; it would be a sort of chronic case of pneumonia after a little while. You will find that that is generally the case. I think that the lungs get partially solid, more particularly in the lower part.

10,666. (*Mr. Holland.*) With puerile breathing ?—Yes.

10,667. With little or no mucus rattle ?—No ; very little ; but if he is badly treated as to diet you will find that it will break down, and a small cavity will form. I have known very large cavities formed in cases of that sort.

10,668. From the breaking down of the substance of the lung ?—Yes. He may then go on, if he has good living.

10,669. (*Chairman.*) Even in that stage a man may continue to live for sometime ?—Yes, for years. I may say for three or four years.

10,670. (*Mr. Holland.*) After the formation of a distinct cavity ?—Yes ; I think I could point out 20 men to you. I think it becomes then just as the sputa in a common case of consumption. After a time I see very little difference.

10,671. Is it mixed with blood ?—Very rarely with blood, unless it is a very large cavity indeed ; if it is large it may as well open into a blood vessel from that cause as in the case of consumption, but we very rarely have large attacks of hæmorrhage in miners' disease ; it is sometimes tinted, and very frequently a man will come and say, "I spat up so much blood this morning." We inquire how much, and it may amount to a teaspoonful or a tablespoonful ; that is very frequent indeed, but there is very seldom any large amount of blood as the disease goes on.

10,672. (*Chairman.*) A man in that state working on the surface and eating good food may live on for years ?—Yes.

10,673. (*Mr. Holland.*) Is the blood mingled with pus ?—Yes ; they will spit up distinct corpuscles of blood and pus, but rarely any lung tissue.

10,674. The sputa is not generally offensive ?—No. I do not know whether abscess of the lung is more common here than it is elsewhere, but I think for the last 12 months we have had as many as 20 cases of pure abscess of the lung ; not altogether in cases of miners.

10,675. (*Chairman.*) Is there any way of accounting for the disease from which miners peculiarly suffer ?—I think that a great deal of it arises from their climbing, and that another cause is the impure air that they breathe ; that I am quite certain of. I do not think that the alterations of temperature have so much to do with it. In the Gwennap district we do not find that the miners, where the mines are very deep and very hot, are more subject to miners' disease than others. I do not think that they are so much. I think you will find in the Illogan and Redruth parishes, comparing the population, a greater proportion of miners' disease than in Gwennap parish.

10,676. (*Mr. Holland.*) Have you met with many cases of pure bronchitis ?—Very seldom.

10,677. Do you consider that the miners' complaint is chiefly bronchitis ?—No, it is not ; it is generally pneumonia. The lung gets solid ; you meet with solid patches of lung here and there, in parts.

10,678. Is bronchitis mixed with pneumonia common ?—Yes, that is a common disease, but we seldom meet with bronchitis.

10,679. Do you rarely find the upper part of the lung much diseased ?—Very rarely the upper part of the lung in the early stage of the disease.

10,680. Is emphysema of frequent occurrence ?—It occurs occasionally, but not very marked. I do not think it is more marked among the miners than in any other classes of labourers.

10,681. Is mucus rattle in the bronchial tubes a frequent permanent symptom ?—No, I think not.

10,682. Do you attribute much of the miners' complaint to the irritation caused by the dust ?—Not a great deal.

10,683. Or the powder smoke ?—I have no theory as to that.

10,684. Has the irritation caused by the powder smoke appeared to be an exciting cause frequently ?—Not very marked.

10,685. Is a thickening of the lining membrane of the bronchial tubes of frequent occurrence ?—In the second stage of the disease, but not in the early stage. I think that that is to be accounted for by the effort made in coughing, and by the great effort that the act of respiration produces.

The witness withdrew.

Adjourned to Helston To-morrow at half-past 11 o'clock.

HELSTON.

Friday, 8th August 1862.

PRESENT:

The Right Honourable Lord KINNAIRD, K.T.
JOHN ST. AUBYN, Esq., M.P.
RICHARD DAVEY, Esq., M.P.
P. H. HOLLAND, Esq.

The Right Honourable Lord KINNAIRD, K.T., in the Chair.

Captain JOSEPH VIVIAN examined.

10,686. (*Chairman.*) You have charge of Huel Fortune?—Yes.

10,687. Have you charge of any other mines?—Not at present.

10,688. You have sent in to the secretary a list of the men in your employment?—Yes.

10,689. Can you tell us about the number of men under ground and above ground?—We have altogether 520, out of which there are about 270 under ground.

10,690. What kind of mineral does your mine produce?—Tin.

10,691-2. Entirely?—Occasionally stones of copper.

10,693-4. What is the deepest level at which you are working now?—95 fathoms from the adit; 120 fathoms from the surface.

10,695. How do the men ascend and descend?—By ladders.

10,696. Have you any skips or kibbles?—We have skips and kibbles both.

10,697. Do you find the skip more economical for working than the kibble?—Yes, in deep levels, not at shallow depths.

10,698. Do the men ever attempt to come up in the skip?—Never; we never allow that.

10,699. They never do it?—No, they never attempt to do it; a man would be immed ately discharged if that were the case.

10,700. Is it worked with a chain?—With a wire rope.

10,701. Do you think that it would not be safe for the men?—I should not recommend it; I should not like to try it myself.

10,702. Have you ever seen a skip used for taking men up and down?—No, I have heard of them; our ladders are very good indeed, and it is on a flat underlie, that makes it more easy; it is about 4½ feet in a fathom.

10,703. For working an inclined plane I suppose the skip is best?—Certainly, that is where we work the skip.

10,704. Are there any close ends which you are working now?—None; our mine is very well ventilated.

10,705-6. Have you ever tried the greatest heat?—No; the mine generally is very cold.

10,707. Is it in granite or in killas?—It is in killas, close to the granite.

10,708. In your opinion, is there any difference in the heat or air of a mine whether it is in granite or in killas?—A considerable difference; it is colder in granite.

10,709. Is there naturally less air in a killas than in a granite mine?—I really cannot say; I do not know that there is much difference.

10710. Have you ever seen a case of what is called cold damp in a granite mine?—It has never come under my notice in this country; it has in the Brazils.

10,711. I suppose that the smoke is not long in getting out?—A very short time indeed.

10,712. How long should you say after blasting?—I should think that in the worst parts in the mine the men can resume their work in 20 minutes.

10,713. (*Mr. Holland.*) What is the ordinary time?—It passes away immediately an explosion takes place in our best places.

10,714-5. In 5 minutes?—In less.

10,716. (*Chairman.*) Have the men a fixed allowance of candles with you?—Yes, 2 lbs. a week.

10,717. What do they pay for them?—8*d.* a lb.

10,718. How much a lb. do they pay for powder?—8*d.*

10,719. Do you charge for the barber?—We do.

10,720. How much?—3*d.* a month.

10,721. How many doctors are appointed?—Two.

10,722. How are they appointed?—By the committee.

10,723. What deduction is made for club money?—6*d.* for club and 6*d.* for the doctor.

10,724-5. Is the club for visible accident only?—Yes.

10,726. (*Mr. Holland.*) Is there no allowance for sickness?—No.

10,727. (*Chairman.*) Is the account of the club money kept separate?—It is regularly kept in the mine by the purser.

10,728. Is it laid before the committee?—Never since I have had the management of the mine; but I have been there only about eight months; it has not been laid before the committee in my presence.

10,729. Is it kept as the purser's private account, or is it kept as part of the adventurer's account?—A part of the adventurer's account.

10,730. Have you as manager, or have the men who pay to the club, any means of knowing how the club account stands?—I suppose that the men could ascertain at any time by applying to the purser; that has been the case in all other mines with which I have been connected.

10,731. How many boilers have you?—Seven.

10,732. Have you any fixed period for cleaning them out?—It depends on the nature of the water which we have to feed the boilers; in some places it is necessary to do it oftener than others, but the longest period that we allow any of them to stand over is six months, but that is when the water is perfectly clear; in some cases it is required once in three months.

10,733. During the last eight months you have not had any explosions?—No.

10,734. You have had the management of mines abroad, have you not?—I have never had the management of mines abroad.

10,735. But you have visited mines abroad?—Yes, I was in the Brazils about five years.

10,736. Were you working there?—Yes, in Gongo mine.

10,737. Did you suffer at all from working there?—No; I have been working under ground 30 years.

10,738. In other parts of Cornwall?—In the neighbourhood of Camborne principally, North Roskear.

10,739. Did you ever know a man suffer from working under ground?—No.

10,740. You never met with any man who suffered?—Not any one.

10,741. Then you do not think that the men do suffer from working under ground?—None that ever came under my experience.

10,742. Have you ever been in the Gwennap district?—Never to work.

10,743. What is the hottest level in which you ever worked?—I really cannot tell you. I do not remember the heat ever being taken.

10,744. Have you ever worked ra close end?—Tolerably close, but I never fel any inconvenience from working there.

10,745. How long did you work in a close end?—If it is what is called tolerably close it would be about six hours, but we generally worked eight.

HELSTON.

Capt. J. Vivian.

8 August 1862.

10,746. But if it was close you would work a shorter time ?—Certainly, according to the place. In some places the men have been obliged to be relieved every four hours.

10,747. But they have never suffered from that ?—No.

10,748. You said that you met with cold damp abroad ?—In the Brazils there was a little, but nothing to injure.

10,749. Do you know what the cold damp arose from ?—I think that it was in consequence of using so much new timber; that was supposed to be the reason.

10,750. (*Mr. Holland.*) You have said that the men are not allowed to ride down skips; is that because you think it dangerous ?—I consider it so.

10,751. Or would they interrupt the work ?—They would not interrupt the work in the slightest degree.

10,752. As you think it dangerous you have an objection ?—Yes.

10,753. If it could be shown to be safe your objection would be removed ?—Certainly; but then our ladder being so very easy it is scarcely worth while, and besides that the mine is shallow.

REFORM CLUB PALL MALL

The witness withdrew.

Captain WILLIAM CHAPPELL examined.

Capt. W. Chappell.

10,754. (*Chairman.*) Of what mine have you charge ?—Huel Sithney and Carnmeal United mines.

10,755. Have you charge of more than one ?—Yes, I have charge of Sithney Huel Metal.

10,756. Are those tin mines ?—Yes.

10,757. Have you sent any statement to the secretary of the number of men employed under ground ?—I have.

10,758. What is the deepest level in Sithney and Carnmeal which you are working ?—60 fathoms under adit; the adit is 16 fathoms from the surface.

10,759. Do the men ascend and descend by ladders ?—Yes.

10,760. What is the incline of the ladder generally ?—About three feet in a fathom.

10,761. Have you any hot levels or close ends ?—No, we have the mine well ventilated; with four shafts from surface within about 200 fathoms; two of them are down to the 50 fathoms level, and one to the 20, and the others to the 60.

10,762. What is the lowest level in the other mine ?—130 fathoms; that would be Sithney Huel Metal.

10,763. Do the men ascend and descend there by ladder ?—Yes. We have 10-inch staves; the former plan was 12-inch; we now find the other much easier; and the last few years we have taken out all the old ones, and put in what we call 10-inch staves; the men travel a great deal easier.

10,764. Do the men prefer it ?—Yes.

10,765. Did they not object to the change at first ?—No, they approved of it; it was a little tedious in going down the first time because the step was so much shorter.

10,766. Have you any hot levels or close ends in that mine ?—No; we ventilate it by sinking winzes about every 15 or 20 fathoms.

10,767. How far would you drive an end from a winze ?—They should not be driven more than from 20 to 25 fathoms. If we have a course of tin there is no fear of the winzes going down fast enough, but whether we have tin or not the distance should not exceed the above extent.

10,768. When there is no tin and you are driving a level before a winze is sunk is not the air close ?—Not for 20 or 25 fathoms, we do not find then any of it so as to injure anyone.

10,769. Have you ever found that the candles would not burn either in driving a level or in sinking a winze ?—Yes, I have seen that in winzes, and rather in rises, rising up against a winze; but I think that the great fault in that is that you get an inferior candle.

10,770. Do you think that an inferior candle will go out sooner in poor air than a good candle ?—Much so, and it creates a bad air. There is a great deal of arsenic mixed up in order to harden the inferior tallow, and there you find that that takes great effect on the men.

10,771. What kind of candles do you use, are they patent candles ?—No, we buy our candles at Bristol, and we only allow the men 1½ lbs. in place of 2 lbs., and they really prefer it to 2 lbs.; they cost a little more, perhaps they cost about 3d. a dozen more; then we save ½ lb. on each man, so that the adventurers save by it about five sixths per cent. in the consumption. I think that there is a great fault in the inferior kind of candles.

10,772. What do the men pay for those candles ?—They pay according to the price of them; they pay now about 7½*d.* or 8*d.* a lb.

10,773. What can you get them at wholesale ?—We get them now at about 6*s.* 6*d.* or 7*s.*, and sometimes in the winter we have had to pay as much as 8*s.* Then we never charge a rise; when we commence the year we carry it out for the year.

10,774. Do you alter the price every year to the men ?—About once a year, at Christmas time, in fixing it it may be higher or lower.

10,775. You only alter it if the price of the candles should be lower or higher ?—Yes.

10,776. You fix it every year according to the price ?—Yes. we take in a large stock of candles, which, perhaps, last six, eight, or nine months. If we buy them very cheap we let the men have them at a price accordingly, but if we pay a long price for them, and it falls in a few months afterwards, they must continue to pay that price out.

10,777. In fact the men pay according to the price when the candles are purchased ?—Yes.

10,778. Are you at all particular as to the kind of powder which you use ?—Yes, I am very particular about it. I use a very fine grained powder; it is from 15 to 20 per cent. stronger than the large powder, and makes a great deal less smoke.

10,779. Are your men satisfied that that powder is as good or better for blasting than the large sized powder ?—Yes, they are at present, but it was a long while before we could bring them to it, because the fine powder requires a little more work with it. If they have a wet hole they must put so much more clay in it. It takes about ten minutes longer, that is to say, to get the hole dry so that the powder shall not stick about the hole. It is that which causes extra smoke. When dry it explodes at once and soon passes away.

10,780. Do you think that a more complete explosion takes place with the smaller grained powder than with the larger grained powder ?—Much more.

10,781. Do you ever use cartridges ?—We use them where it is very wet.

10,782. You never use them in dry ground ?—No, they are not required there, but in wet ground I think they are a very essential thing.

10,783. Have you ever seen paper cartridges made by the men, and inserted in the holes ?—Yes, they make them, we supply them with paper.

10,784. Would not that save the powder hanging about the hole ?—Yes, that is where they save a great amount of work. In dry ground they do not require it, but in wet ground I think that either paper or cartridges are very beneficial.

10,785. But even in dry ground, if it saves the powder, and saves the chance of accident, would not a paper cartridge be of advantage ?—No, I think not in any way. In dry ground less powder will do.

10,786. Have you ever had any accident from blasting ?—We have had only one.

10,787. Could you ascertain what that arose from ?—It arose from putting in too large a cartridge in a

small hole. The cartridge was what they call No. 4, and was put into a hole No. 3; it was entirely the men's own fault. I caution them every day, as regularly as can be. In 10 or 11 years we have only had one accident.

10,788. How did that accident happen; did it break the cartridge?—No; in forcing it with the swabbing stick it exploded. The cartridge was so tight that after it got in a certain distance there was a certain amount of air, and it exploded and threw out its burthen, and one of the stones broke a man's hip and the other part went about a man's face; he came up, and I washed him, and his face was full of powder.

10,789. Showing that it had not all exploded?—Yes, because there was no tamping on the hole.

10,790. Then do you think that the mere pressure of the powder with an oak stick would cause an explosion?—Yes, when struck with the mallet, the cartridge being too large for the hole. If it had been only powder it would not have gone off. I think that in nine cases out of ten the accidents happen by the men forcing larger cartridges in holes than they are calculated for. In this instance the ground was exceedingly hard.

10,791. You are quite sure that the man did not use an iron tamping rod to force it in?—No; I took them to task the moment they came up. After I had washed and dressed the men, they told me, and I can reasonably believe them, that it was only wood.

10,792. What priced ground was it?—8*l.* 10*s.* a fathom. We set for the month, and I believe that it was harder when that happened; perhaps if we had been going to set then we should have given a little larger price.

10,793. Was it on the lode?—Yes. We have a rule that if we find the men tamping a hole with the tamping bar we spale each of them half a crown.

10,794. Have you any way of enforcing those rules beyond the spaling?—No; we hang out our rules every setting day, and the men see them, and if they do not like to take under those rules they leave.

10,795. I suppose that the rules are occasionally infringed?—In some instances I suppose they are.

10,796. How many boilers have you?—Two.

10,797. Do you cleanse them out?—We cleanse them out every 12 weeks.

10,798. When a new mine is started are not second-hand boilers sometimes used?—Yes.

10,799. Do you consider that that is quite safe without a very careful examination of them?—No, I do not myself. If they have been in very bad water I think that they ought to be looked very closely into; there are some exceptions where second-hand boilers would do.

10,800. Do you consider that the responsibility with reference to the boilers should rest with the captains and managers?—I think that it should rest principally with the engineers.

10,801. Should you as a manager inquire whether a boiler which was purchased by the adventurers of a mine of which you had charge was in a proper state?—Yes.

10,802. You consider it very important that a boiler before it is put up should be thoroughly tested?—Yes.

10,803. In your experience have you ever had to reject a boiler on account of its not being perfect?—Yes. Every boiler, either new or second-hand, should be properly tested by hydraulic pressure at the foundry by the agents of the mine or on the mine before it is put in use.

10,804. While the boilers are at work should you consider that at certain periods they should be tested?—In the cleansing of them, the person who is employed to test them after they are cleansed can examine them then without any pressure very well, and can see whether they have been eaten away. If there has been bad water, then they must be repaired before you use them.

10,805. Do you think that that would be a sufficient test to prevent boiler explosions?—Yes, if they are properly looked after.

10,806. Is it the business of the manager or captain to see that the boiler is in a proper condition?—It is the business of all, but that is more the engineer's department.

10,807. Have you a special engineer for the mine, besides the stoker?—Every mine has an engineer.

10808. How often does the engineer inspect the boiler?—He comes about once a week.

10,809. But he can only test it when it is cleansed?—Yes.

10,810. Is notice sent to him before it is cleansed, so that he may be there when it is cleansed?—No. I do not think that that is a rule.

10,811. (*Mr. Holland.*) Is the engineer in the habit of going into the boiler himself?—No.

10,812. He trusts to the engineman?—Yes, the agents go in.

10,813. Regularly?—Yes.

10,814. (*Chairman.*) And it is their duty thoroughly to examine it?—Yes.

10,815. I suppose that you have heard of boiler explosions taking place?—Yes.

10,816. Do you consider it dangerous for the men to change in the boiler house?—Yes, in the case of old ones.

10,817. Do you know what the men pay for club money?—They pay 6*d.* a month.

10,818. And how much for doctor?—For doctor they pay 6*d.*; that is, round here.

10,819. Is there a separate account kept of the club money?—Yes.

10,820. Do you consider that the club money belongs to the men or to the adventurers?—To the men.

13,821. Have the men any means of knowing the state of that account?—Yes, at any time, if they ask. There is a debtor and creditor account kept regularly.

10,822. You think that that money should not be applied to the other purposes of the mine?—To no other purposes.

10,823. (*Mr. Holland.*) What pressure of steam do you work your boilers at?—Ours now is only working at 25 lbs. to the inch.

10,824. What are the boilers tested for when they are new?—60 lbs.

10,825. Are they never tested again for strength?—Not afterwards; you must depend upon the wear, and upon the state of the water, and examine them as you cleanse them out.

10,826. You never work them nearly up to their bursting pressure, do you?—No, not any that I have been connected with. I have never known any work within 25 or 26 lbs. of that.

10,827. When the plates were half eaten through you got new plates?—Yes, we should take out the old and replace them with new.

10,828. Is that as soon as you see corrosion of the plates?—Yes, as soon as we see corrosion of the plates and the wear we are compelled to do it, because they leak water, and when they leak water they leak steam.

10,829. Do you wait for leakage?—No; but if we did not replace them we should have these leakages, which would be a great expense.

10,830. Is it customary to test boilers to something like double their working pressure?—Yes.

16,831. You have said that you believe that the shot which you have mentioned went off from cramming in too large a cartridge with the swabbing stick?—Yes.

10,832. Do you think that possible?—I really think that it is correct from what the men told me, after I had them up before they really knew what their hurt was; in fact I questioned them when they were down in the level.

10,833. Have you seen the cartridge ignited in a blast hole by the pressure of the stick?—Yes, when struck with the mallet. I have seen that in the bottom of a shaft sinking in ground at 18*l.* a fathom.

10,834. You speak with perfect confidence of the

HELSTON.
Capt. W. Chappell.
8 August 1862.

correctness of that?—I saw that in Sithney Huel Metal about nine years ago.

10,835. Would it be possible to do that with a cartridge?—This was with a cartridge.

10,836. Could you show that experiment with a cartridge?—It could be done under ground, not on the surface

10,837. Could you light a fuse between two stones alone?—No.

10,838. You told us that the candles sometimes burnt dimly in the rises?—Yes, where there is poor air and inferior candles.

10,839. Have you noticed that bad candles go out in poor air sooner than good candles?—Yes.

10,840. Is there also much more smoke?—Yes, an inferior candle will not burn in poor air so well as a better quality one.

10,841. You also said that you saved half a pound a week per man in candles by using better ones?—Yes.

10,842. It is cheaper?—It is cheaper in the end.

10,843. 1½ lb. of good candles cost less than 2 lbs. of bad?—Yes.

10,844. So that they really are cheaper?—Yes.

10,845. You said you prefer fine-grained powder to large-grained powder, because it is from 5 to 20 per cent. stronger?—Yes, and it makes less smoke.

10,846. How much dearer is it?—It is the same price.

10,847. Then it is cheaper?—Yes.

10,848. Then it is a mere prejudice to use large-grained powder?—I have seen it as large round as my little finger. I suppose that the merchants get a little more profit out of the large powder than out of the other, but I do not know.

10,849. It is manufactured purposely for blasting?—It may answer better in wet ground; the very large powder does so.

10,850. Is it not better to dry the hole thoroughly, and to use the stronger and therefore cheaper powder?—Yes, that is what we do.

10,851. There is a prejudice or an opinion that slow-burning powder is better for blasting than quick-burning powder; is that wrong too?—It may answer in very shallow mines and easy ground. You do not find the ground so stiff nor hard in shallow mines as you do in deep mines. When you get down 150 or 200 fathoms you then mostly find the rock a little harder than you do up 30, 40, or 50 fathoms from the surface. We have tried both powders, but our men prefer the fine.

10,852. Do you think that the powder smoke is very annoying or injurious to the men; do they complain much of it?—No, they do not complain; the only thing in which I think it hurts them is where they have very poor air, where the mines are not ventilated for the powder smoke to pass away.

10,853. Then they do complain of it?—Yes.

10,854. Then the powder smoke hangs about a long time?—Yes.

10,855. And then they complain of it?—Yes.

10,856. Do they complain that it takes up their time, or that it injures or annoys them?—In a poor-air mine it takes up their time, because they cannot go back to the holes.

10,857. That is what they complain of, perhaps?—Yes.

10,858. But do they complain that it injures them?—No, they never complain that it injures them at all.

10,859. You have stated that when the hole was not well dried the powder made much more smoke?—Yes, because it sticks about the outside of the hole more.

10,860. That is then another reason why they should use fine powder, and be compelled to dry the hole perfectly?—Yes.

10,861. (*Mr. St. Aubyn.*) Do you use a man-engine in your mine?—No.

10,862. Have you had any experience of it in other mines?—I have seen them, but never have been connected with them.

10,863. What depth are you?—60 fathoms. We do not require a man-engine.

10,864. From what you have seen of it you would not think that in mines of a less depth than 100 fathoms the introduction of the man-engine was advisable?—I should not.

10,865. Have you had any experience of the skip for drawing men?—No, only for drawing stuff up; that is the same kind of thing. But the skip for the stuff comes up one part of the shaft, and the men the other.

10,866. Have you ever compared the relative advantages of the skip and the kibble for drawing stuff?—I have. In some instances the kibble will do much better; it is according to what kind of shaft they have.

10,867. According to the under-lie?—Yes.

10,868. What amount of under lie do you think would make it desirable to use the skip?—If you had a flat under-lie you should use a skip by all means.

10,869. How much under-lie in a fathom?—From 3½ feet to 4 feet in a fathom. If the under-lie is 4 feet in a fathom by all means have a skip.

10,870. If the under-lie was more than from 3½ feet to 4 feet in a fathom you would use the kibble?—No.

10,871. Why?—I should use the skip, because there would be less friction. The skip, however, except it is very well put in, is liable to get frequently off the road.

10,872. I understand you to say, that unless your skip is very well put in it is liable to get off the guides?—Yes.

10,873. Is there any reason why it should not be well put in?—If your shaft is not commenced and sunk at a proper size and angle the first time, you cannot alter it afterwards. If you go and sink your shaft 50, 60, or 100 fathoms, you would not think of putting in your skip. You may have your shaft sunk zig-zag, or not quite large enough, and you would have to do the best you could to put your road in and to come down where the road is perfect.

10,874. Do you know that the skip has been used where there are angles, and that by the use of proper shafts at those angles it has answered very well?—I am not aware that where there are many angles it has answered well.

10,875. With regard to drawing men, have you ever been at South Frances?—I have been there, but have not been under-ground there.

10,876. Have you seen the skip there?—No; I do not think that they had a skip there then. It is five or six years since I was over there.

10,877. (*Mr. Davey.*) You have stated that you accounted for much of the impure air under-ground from arsenic being present in the candles; how do you detect that?—From the colour of them and the smell, the smell principally.

10,878. Do you usually find arsenic in candles?—Yes.

10,879. In whose candles?—In some of the Cornish candles.

10,880. The only mode which you have of detecting arsenic is by the smell?—Yes, the smell is very strong. We now have Bristol candles in our mines, and they are more like the candles which you burn in a house.

10,881. You have also stated that when a boiler is cleansed, by looking over it, and detecting any hole or anything of that sort, you prevent explosion. How do you account for explosions generally?—In some instances it is owing to the engineman being asleep; I suppose there is no doubt of that; and in some instances it is owing to the boilers being perhaps worked too long.

10,882. Do you think that a boiler would explode if the water was at a proper gauge?—I do not think that it would except there was a much higher pressure on it than it really would bear.

10,883. Have you ever found an instance where the engineman had put an extra weight upon the safety valve?—No, I have never found it with any that I have ever been connected with yet.

10,884 Might not that be a cause of explosion?—Yes, that would be a very likely way.

10,885. With respect to the small powder, is it as fine as sporting powder?—Not quite so fine as that.

10,886. How do you know that it is 15 or 20 per cent. stronger than the large-grained powder?—We have weighed it off and tested it with the large powder in the same end several times.

10,887. Then you have put a less quantity of the fine-grained powder than of the other?—Yes, the fine-grained powder will go down; you can press it all down and make it all firm in the bottom of the hole, but with the larged-sized powder such as the size of your finger there is a great deal of space between which contains no powder at all.

10,888. (*Mr. Holland.*) Are accidents frequent in putting in the first tamping?—No, not with clean powder; they are very common in putting in the last.

10,889. Are there many accidents from picking out the tamping?—No; they arise principally from boring it out.

10,890. Can you suggest any mode of preventing those?—The only thing that we have, and we find it very beneficial, is what we call a pricker, which is three-eighths iron, and the end turned, so as to loosen it, and then a scraper goes in and brings it out.

10,891. Is not that dangerous;—No, I never find any accident in picking out the hole with a picker, but where they bore it out, that is where an accident occurs; but I do not think that much of that is done now; men are cautioned against it I think by most agents.

10,892. You think that picking out is safe, but that boring out is very dangerous?—Yes.

The witness withdrew.

Mr. JAMES WEARNE examined.

10,893. (*Chairman.*) I believe that you are surgeon to different mines in the neighbourhood of Helston?—Yes, six or seven.

10,894. Have you been for some time surgeon to those mines?—Yes, for the last 30 years; not sole surgeon to all those mines. I have been surgeon of many mines in this neighbourhood for 30 years, but I do not know any one mine that I have been surgeon of for 30 years.

10,895. During your experience as surgeon have any men come under your notice affected with what is called miners' disease?—I do not know what miners' disease is.

10,896. Affected with consumption?—Knowing of course that I was coming before you to-day I looked about among my patients to see whether I could find a case of consumption, and I am not sure that I could find one.

10,897. Are your patients affected with any illness specially applicable to miners?—I think that that would depend in a great measure upon the depth at which the men were working.

10,898. Is there any peculiar illness to which miners are subject?—Not one that I know of.

10,899. Do you think that there is any one disease not peculiar to miners but which prevails amongst any number of miners?—Yes, I should say bronchitis; they suffer from chronic bronchitis.

10,900. Is there any other disease?—I do not know that there is.

10,901. Have you observed the case of any miner in an early stage of the disease, and watched its progress till he has died?—I am obliged to do so.

10,902. In those cases it is bronchitis?—I think so; you may have a little dilatation of the air cells, for instance, and it may run into asthma; but I think that since we have become better acquainted with the stethescope, and the proper examination of the chest, we have not so many or are not likely to have so many cases reported as consumption.

10,903. In your opinion what is the state of the disease when it first shows itself in any miner working under ground?—I should think that it was congestion of the mucous membrane.

10,904. (*Mr. Holland.*) You mean congestion of the lining membrane of the bronchial tubes?—Yes.

10,905. (*Chairman.*) What is the next stage after a man has been affected which the disease assumes?—You would get inflammatory action, and you would get a very large discharge in some instances—great expectoration; in others you would not; and you might get ulceration, and you would get the air cells and air tubes closed up, and you get dilatation of the bronchial tubes, which of course would render a man less able to labour. You would then in the end of the matter get the heart disordered, and have, more especially, perhaps, dilatation.

10,906. What is the nature of the expectoration in the earlier stage?—Generally a yellowish mucus.

10,907. Does that increase as the disease goes on?—It is not always that the form of the disease is exactly alike in every case; you may have cases of chronic bronchitis with very little expectoration.

10,908. But where it proceeds so as at last to endanger life or to prevent the man working, does the expectoration ever show anything peculiar?—Nothing tubercular. They spit up a great deal of powder smoke, as we call it. I have seen the same thing in blacksmiths when they have been working at the smithies and so on; but it is very remarkable for how very long a time a miner will spit up this black stuff after leaving a mine, and after having been ill for months.

10,909. How long, in your experience, have you ever seen it?—I cannot speak exactly. I should say three or four months after he has been laid up ill, and has retired from his employment. I do not say that it is generally the case, but I have seen it.

10,910. (*Mr. Holland.*) That is about the limit, is it not?—That is, as well as I can recollect. I cannot give any limit to it. I could not say, for instance, that I had seen it after the men had been away 12 months or 6 months. I think that within six months you may see it.

10,911. (*Chairman.*) When men have come to you so affected have you seen them quite recover if they have got back to work in the same mine?—You sometimes see them recover, and frequently.

10,912. Would you recommend a man to go back to the same work or not to go back to the same work?—That would depend upon his age. I am constantly making little arrangements for a miner, and using my influence for him as far as it will go to get a little work at the surface if he is 50 years of age, and if he has a bad cough, or I advise him to get some other occupation.

10,913. But if a young man was so affected you would not do so?—I do not say much to the young men upon the subject; indeed they are not so often affected.

10,914. At what age should you say that they are generally affected?—I should say about 45; from 45 to 50 you find them beginning to fail in that way very much.

10,915. How do they describe to you their feelings on being first affected?—Very generally that they want to bring something up. I very often scold them because they are constantly trying to expectorate, and I say, "Why are you bothering yourself in that way; "wait till you can bring something up, and do not kill "yourself by trying to do it." They sometimes use very great exertions to bring up something that is not inclined to come away.

HELSTON.

Mr. J. Wearne.

8 August 1862.

10,916. (*Mr. Holland.*) They feel as if there were something ?—Yes.

10,917. (*Chairman.*) You think that it aggravates the disease ?—I am sorry to see the men doing it, when I know that there is nothing to come away.

10,918. Do they feel any pain at the pit of the stomach and loss of appetite ?—Not particularly.

10,919. They have not complained to you of that ?—Not particularly. In this neighbourhood we are differently circumstanced from what they are in many parts of the county ; our mines are shallow, and I fancy that the air is better, that the water is colder, and the men's stomachs do not give way as they do in deeper and hotter mines.

10,920. Can men so affected climb the ladders ?—They do climb the ladders.

10,921. Does that aggravate the disorder ?—Of course a man cannot climb so well, and of course if a man is coming up from a deep mine it aggravates the man's complaint. I must be clear in this, because it is my duty to say that I have very often said to a man, "You have got a family." "Yes." "You must go "to work all the sooner. I wish you had not any "family." I go to another man and I say, "Have "you any family ?" "No." "Then you must take "a holiday, a week or ten days, or a fortnight."

10,922. Do you think that a holiday is important for recovery ?—I think so, very frequently

10,923. And would that tend to complete recovery ?—I do not think that it tends to perfect recovery. It might tend to it if a man was put under very favourable circumstances at once, but a man is very much relieved by his holiday. When once affected, I do not think they ever become perfectly sound again, or not frequently.

10,924. But by working on the surface they may live a long time ?—Yes, and do very well.

10,925. But if a man so affected went down to work again, what would be the period of his existence ?—I cannot state. It would depend upon how far the disease had gone ; but I am giving you my practice towards the men. I am always very anxious when once they have thorough chronic bronchitis to prevent their going under ground at all.

10,926. Then it is your opinion that the disease from which they suffer is chronic bronchitis ?—Yes, and the consequences which would result from chronic bronchitis.

10,927. (*Mr. Holland.*) What do you think that it commences with ? Do you think that it begins with irritation of the bronchial membrane ?—Yes.

10,928. Followed shortly by thickening or congestion of that membrane ?—Yes.

10,929. Is chronic bronchitis an early disorder ?—I think that you would get common bronchitis, and that when the miner had worked on with the same symptoms you would get chronic bronchitis. You would get larger expectoration, which you would not have so much at first.

10,930. Does the effort to expectorate without being able to do so often continue a long time ?—I do not know that it does very long.

10,931. A month or two ?—Yes, I dare say that it does, but I have never had an opportunity of watching as to its duration. I fancy that after a man has been labouring under disease of the lungs for a considerable time it rather disappears when he begins to have a free expectoration. The membrane also possibly gets thinner, I think, after there has been very free expectoration from it ; but the bronchial cells would get dilated, for instance.

10,932. And the bronchial tubes would be contracted ?—Yes.

10,933. You have spoken of the heart being disordered ; do you think that that is a consequence of the lung disease, or independent of it ?—I think that it is a consequence of it.

10,934. You think that it is in consequence of an impeded passage of blood from pulmonary circulation ?—I think so ; that the heart participates in the disordered state of the lung, the lung not performing its functions well.

10,935. That it throws a heavy labour upon the heart ?—Yes.

10,936. Have you noticed whether the right side of the heart is more dilated than the left ?—We have never had a post-mortem examination, but I do not think that the left side is much affected. I think that the right side is more affected. I think that the left ventricle is the soundest. I have thought it less disturbed, but I have never had a post-mortem examination at all.

10,937. Have you seen pneumonia as an early symptom ?—I do not see pneumonia amongst them very frequently, unless it is in the younger and stronger men.

10,938. But not as an earlier symptom in the older men ?—I see pneumonia very seldom amongst miners. If I expected a case of pneumonia I should expect it in the young men rather than in the old ones.

10,939. Are these mines dusty ?—I was never down but two or three times in my life.

10,940. Do the men complain much of dust in them ?—They complain of powder smoke sometimes. In our neighbourhood it is generally very wet.

10,941. They are all killas mines here, are they not ?—No, we have granite mines.

10,942. Have you noticed any difference in the men working in granite or in killas mines as to this disease ?—Our killas mines are very few. I do not know that we have more than two or three in the neighbourhood, and they are very small mines.

10,943. What do you think is the cause of the irritation of the bronchial membrane ?—I think that the smoke and dust would be the most likely causes, the carbon and particles from blasting, and so on.

10,944 Mechanical irritation ?—Yes.

10,945. Do you think that that is more likely than chemical irritation ?—I do not think that there is any chemical action in the case.

10,946. Do you attribute much to the alternations of temperature ?—Yes ; I am bound to admit from general experience that they must make a difference. I have been down in Dolcoath between 200 and 300 fathoms, when it has been almost impossible to live there ; but in this locality I do not think that there is anything of the sort.

10,947. You say that the men here break up in health at about 45 or 50. We have been told earlier ages in the middle of the county ?—That is very likely, but I do not think that our men give way much sooner than that. I am speaking in a general way as the result of practice.

10,948. Have you noticed any great improvement in the health of the miners during the 30 years that you have practised here ? Do they break up later in life than they did ?—I think that they do. I think that our men are better rather than worse.

10,949. They keep their health later in life ?—Yes. I think that they live better and are clothed better. I think that the men are better in health.

10,950. They continue in health later in life ?—Yes.

10,951. Is that a very strong impression ?—Most decided in this neighbourhood. In Breage, for instance, and those neighbourhoods, I think that our men are better men at 50 than they used to be. I do not know that the cause is to be attributed to any improvement in mining. I think that there are other reasons for it.

10,952. To what do you attribute that improvement ?—To better clothing, better living, and better habitations.

10,953. Are dries more commonly provided for the men ?—Yes, certainly. I remember the time when there were no dries.

10,954. Do you attribute much importance to that ?—I think that it makes the men more comfortable.

10,955 Does it shield them much from catching cold in coming from their work ?—Of course it would be imprudent to put men into cold clothes coming from the mine in a state of heat ; but sometimes the dry is

very hot, and I do not know that that is not very bad.

10,956. They get dry clothes on?—Yes. I do not know that the dry hurts them; if so, I would tell the adventurers at any time.

10,957. Are they in the habit now of taking down food into the mine more than they did?—I do not know.

10,958. Are they more careful to keep out of powder smoke than they were?—I do not know.

10,959. Are you clear that the black spit is carbon?—I think so. I have never examined it chemically, but it has all the appearance of carbonaceous matter.

10,960. Do you feel sure that it is not any secretion of the lungs?—It is decidedly not.

10,961. It cannot be bronchial secretion?—No; besides that, it is very profuse.

10,962. Where you found a case of black stuff continuing for many years, should you attribute that to work in the mine?—I do not know that I should.

10,963. You only know that it is black?—I know that it is black, and that that is carbon; that it is not an animal product.

10,964. If you heard of a doctor, who said that he had a patient who spat up black stuff for ten years, after having worked in a mine, would you believe it?—I would not believe it.

10,965. It might be from a smoky chimney?—A smoky chimney, I think, would not be sufficient to produce it.

10,966. (*Chairman.*) There are a great many agriculturists in this parish?—Yes, and the neighbourhood is principally agricultural.

10,967. Do you observe any difference between the state of health of the miners and the agriculturists?—The miner has generally less fat about him—less flesh about him, so to speak; but he is generally more muscular.

10,968. (*Mr. St. Aubyn.*) He is in a better condition?—In one sense he is.

10,969. (*Chairman.*) Is he in a better condition to resist disease?—No.

10,970. (*Mr. Holland.*) Which life would you recommend to an insurance office?—The agriculturist. I think it is a duty, if a man is a miner, to state that fact in giving a certificate.

10,971. (*Chairman.*) Which of the two lives best?—I think that the miner lives just as well as the agricultural labourer.

10,972. But not better?—But not better. I think that he takes more animal food than the agriculturist, but not more food altogether. As a class, the miners are more irregular than the agriculturists.

10,973. You have stated that you think it unwholesome after coming up to go into some of the dries when they are hot; is there much dust in the dry?—I think that it must be a little dusty, because as the clothes dry the dust gets into the air.

10,974. Therefore it would be better if the clothes were dried in another place?—Yes; and if there was a warm place for the men.

10,975. You think it advisable to have a warm place for the men?—Yes, of a certain temperature; but not, generally speaking, the same as that of the dry.

10,976. And you think that that should be in all the footways?—Yes. I presume that whenever a man is made uncomfortable by change of temperature, or any other cause, it is likely to injure him. I think that the miners would prefer it; and it is always the interest of the adventurers to make the men healthy and comfortable, and to keep them up.

10,977. You would not recommend their changing in the boiler-house?—No, that is very hot, and we have seen very melancholy accidents happen; a boiler bursts and the men are blown to pieces; you could not recommend it officially.

10,978. (*Mr. Holland.*) Do you speak of the blowing up of the boilers as a real practical danger?—Yes.

10,979. Is it so frequent as that?—It is not very frequent, but I do not think that any person would be justified in recommending the miners to change in the boiler-house; the boilers are sometimes becoming weak. There was a case at Marazion the other day where a boiler was known to be weak, and it exploded, and I think killed two men. That is not the only case which I have known, and that is the reason why I should recommend the Commissioners to avoid looking upon that as a proper place for the men to dry their clothes in or to go in at all.

10,980. You have stated that fewer cases are reported as consumption since the use of the stethescope?—Yes; I do not mean that there would be less of the disease, but it would now be called bronchitis properly, instead of consumption improperly; that the correct distinction would be made between bronchitis and consumption.

10,981. But is there less of the disease bronchitis than there was 30 years ago?—Yes, I think that there is less disease altogether among the miners.

The witness withdrew.

Mr. THOMAS GILL examined.

10,982. (*Chairman.*) Of what mine have you the management?—Of Great Wheal Vor United.

10,983. Is it a tin or a copper mine?—Tin.

10,984. I believe it is only in a part of the mine?—It is in the south part of the mine.

10,985. It was formerly, was it not, one of the largest and deepest mines in the county?—Yes.

10,986. What is the greatest depth at which you are working now?—At about 162 fathoms.

10,987. Can you state the number of men who are employed under ground?—There are 129 men and 10 boys.

10,988. What is the total number of persons employed?—358.

10,989. How do the miners go up and down?—They ascend and descend by ladders.

10,990. What is the distance between the staves of the ladders?—10 inches.

10,991. Are there are any hot levels in the mine?—No, our mine is not very hot at present.

10,992. Are you driving any close ends?—No, only one that we shall ventilate now in the course of a week; we have a rise going up that will communicate at the 152 fathom level to the 142 fathom level in 10 days we expect.

10,993. What is the deepest level at which the miners are working at the present time?—162 at the bottom.

10,994. Where this work is going on that you have just alluded to is at the 152 fathom level?—Yes.

10,995. How is the air at the 152 fathom level?—The air is not bad there.

10,996. Have you tried it at all?—No; we have put in a machine because the air was a little close.

10,997. How did you judge whether the air was close or not?—By the burning of the candle.

10,998. Did not the candle burn well?—No; and the end being very wet we have a great deal more trouble where the air is a little weak in the wet ends than in the dry ones, in keeping the flame of the candle upright.

10,999. Is there a machine at work there now?—Yes.

11,000. What kind of machine is it?—A fan machine.

11,001. Is it worked by a boy?—Yes.

11,002. Where is it placed?—It is placed back within 3 or 4 fathoms of the shaft.

11,003. How near are the pipes taken to the end of the level?—To within 14 or 15 feet.

11,004. Do you mean from the bottom of the rise?—No, it is in close to the end at which they are driving west.

11,005. You are driving a rise?—Yes, they are rising at the back of the same level.

HELSTON.
Mr. T. Gill.
8 August 1862.

11,006. How far is the rise from the end of the level ?—I should suppose about 14 fathoms.

11,007. Is the air in the rise close ?—No, we have a branch of the pipes going up into the rise.

11,008. And going to within 14 or 15 feet of the end of the level ?—Yes.

11,009. Where is the fan placed; is it near a winze or a shaft ?—It is near a shaft.

11,010. How far has the air to be driven ?—To about 20 fathoms, that is the greatest distance; it is a very short distance for a fan machine, for our air is not very bad; not where we placed the machine to force the air at first.

11,011. In putting in a rise or sinking a winze is the air close ?—Yes, it depends upon how far it is off from any ventilation or from any current.

11,012. What should you say the distance would be ?—I have seen bad air at about eight or nine fathoms to the east or west of a current of air that was passing up and down; sometimes you might drive 100 fathoms, and the air would not be so bad as at nine or ten fathoms; it depends principally upon the strata, and how the damp forms.

11,013. And whether you are working in killas or in granite ?—Yes.

11,014. In what kind of strata is bad air more likely to be produced ?—I think in granite principally; I think that the foul air in granite does injure the miners more than in any other kind of strata that I have seen.

11,015. Another term has been used for the cold air that is found in granite, namely, cold damp. Is that what you would understand by cold air ?—Yes.

11,016. Is that in your opinion different from poor air ?—No; oftentimes the air does cause this cold damp in the levels.

11,017. In a level where there was cold damp, if there were many men working in it the evil would be aggravated ?—No.

11,018. On a Monday morning, when the men return to their labour, is it found that the cold damp is worse ?—Not in the ordinary way of working, I think, because in going down to an old mine we oftentimes find a greater chill in an old mine that has been left idle for some time than what we do in going down a mine of some magnitude that has been in course of working a few days before; there is a great difference; you find a chill and a cold dampness in an old mine more so than in a mine that is in the regular course of working.

11,019. Do you think that that cold dampness is more injurious than what is termed poor air in close ends ?—We miners generally consider it so.

11,020. What effect has the cold dampness upon the candles ?—It does not take much effect; it is only just upon the system.

11,021. You cannot judge of it by the candles ?—No.

11,022. Have you ever observed in sinking a winze in any mine the cold dampness of the air so bad that the men could not work in it ?—Yes, I have seen cold damp many times so that we have been obliged to throw down furs to try to break it, and have many times thrown down powder and set fire to the powder before we got it away, and burnt hot lime; I have seen places before now where a candle has been just cooled out four or five feet above the back of a level; there has been a current of air at one place, and you could pass along very well, and damp has formed there, and I have put a candle to it, and it has quenched it just the same as if it had been dipped in water; the damp would form just in the back of the level above us. That was near Devonport, and that was the only mine in which I ever saw it.

11,023. Could you detect the cold damp by the eye ?—Yes, we could when we came to examine it afterwards.

11,024. What appearance had it ?—It had a lightish colour, more so than the air in the level, because it is generally a smoke or a steam that is passing through the levels.

11,025. Do you think that the cold damp is generally a steam or a smoke that is passing through the levels ?—No, I say that it generally looks whiter.

11,026. What effect was produced by throwing powder down upon it and igniting it ?—It did not take any effect upon it, not the least; I have seen the damp form in a winze in a bottom level just the same as you would see a fog at a certain distance.

11,027. Did you expel it by the expedient you resorted to ?—No.

11,028. Could a miner have gone down to work in the place at the time ?—No.

11,029. Would the fan machine drive it out ?—Yes, very soon.

11,030. Is the part of the mine in which you are now working open to all the old openings, or in communication with them ?—No, it is quite distinct from the old mine; this is a side lode, and we are nearly half a mile to the south of the old mine.

11,031. Does the timber decay where you are now working ?—Not very fast, not so fast as in other mines.

11,032. I suppose that in a dry mine the timber is more likely to decay than in a wet mine ?—Any decay of the timber depends a great deal upon the strata too.

11,033. Does timber decay more in granite than in killas ?—Yes, I think it does; but then, if there is water constantly pouring over the timber, either in granite or in killas, it will preserve it a great deal longer.

11,034. Particularly if that is copper water ?—Yes, that will preserve the timber for a considerable time.

11,035. How many under ground captains are there in your mine ?—Two.

11,036. In the end that you are now driving, have you ever observed how long the powder smoke will remain before the men can go to work ?—Sometimes it might lie there for 10 or 15 minutes, sometimes three or four minutes; it depends upon the wind at the surface, and how the current of air is running through the mine; that makes a considerable difference; it is just the same as the draught of a chimney.

11,037. Where you are now driving is it the fact that in 10 or 15 minutes you get rid of the powder-smoke ?—Yes; we have been driving in a mine, but if the smoke would leave it in about 10 minutes any man could go in to work.

11,038. How many shafts are there in the mine ?—Two.

11,039. Is one a downcast and the other an upcast shaft ?—Sometimes; it depends upon how the wind changes.

11,040. Does one shaft suddenly change from a downcast to an upcast ?—Yes, very suddenly; perhaps it will change in two minutes after the wind changes, and oftentimes we are obliged to raise the shaft to draw a current when the shafts are at an equal level.

11,041. By making one shaft higher above the surface than the other you would create an upcast current ?—Yes, down the one that is the highest.

11,042. Could that be done so as to make it always an upcast ?—Yes, I think so; I do not know, I do not think it would make much difference to the mine, an upcast or a downcast; as long as you have a current of air passing through the mine it is sure to clear the mine of the smoke or the foul air by driving it to the lower shaft as well as to the higher one; you must go to a great expense always to bring the current of air to the highest shaft, and I do not see the advantage of it.

11,043. Would it be desirable to have one shaft always an upcast and the other always a downcast ?—No, I do not think it would; that is what I said before, because I think it is as well for the current of air to go down through the high shaft and come up the down one as to go the other way.

11,044. As there is frequently a change the air cannot be constantly taken out of the mine ?—Yes, if the current of air should be running east now it will clear the mine as well as if it turned and ran west.

11,045. But, supposing it turned round and went north, it would then take back all the smoke and the air to the east shaft ?—No ; if it is once taken out of the levels and brought back near a shaft it is at the surface, perhaps, in two minutes; it is discharged there.

11,046. But, supposing the point of discharge is changed from one shaft to the other, or from one end of a level to the other, then it must be taken back again the way it came, in order to escape ?—I do not think that that signifies but very trifling.

11,047. Suppose there was no wind, and it was a muggy day, would there then be any ventilation at all ?—Yes, there would be then ; but in some mines which I have seen, which have not been well ventilated, I have seen them obliged to stop for some days until the wind should rise a little again.

11,048. Have you known of mines where they have been obliged to stop altogether for that reason ?—For a day or two as the shafts have been nearly at a level, but by raising one shaft a little higher than the other of course the draught does run.

11,049. In the case where the working was stopped, did it occur when the air went sometimes up one shaft and sometimes down the other ?—That I cannot say, not at present. I know that the two shafts of the mine are shallow, and the two shafts were just of equal height.

11,050. Were any means taken to remedy that defect ?—Yes, one shaft was raised a little higher, a few feet higher, than the other.

11,051. Did that answer the purpose ?—Yes, it did.

11,052. Then the upcast always afterwards went up one way ?—Not until we got one formed in a rise of the ground ; we sunk a deeper shaft, one with a higher top to it.

11,053. Did you ever find the highest shaft act as a downcast ?—Yes, I have ; and we have one of the kind now that does very often.

11,054. Then the raising of the one shaft is not a complete remedy ?—But then it causes a better circulation, a great deal, of the air under ground.

11,055. Have any accidents occurred in your mine from blasting ?—No ; we have not had any accidents from blasting, not since I have been in Wheal Vor ; no more than that a man some time ago set fire to two blasts, and one ignited, and he thought the other, what the miners term, missed ; but he thought the hole ought to have exploded, and just as he got on upon the hole the hole exploded and gave him several scars in the hands, and lodged a stone in his chest.

11,056. He returned to the hole against orders ?—Yes. The doctors extracted the stone, but he had a hole cut right through ; he was obliged to lie by far six weeks, but I think he is working now.

11,057. Are there any means that you can recommend for the purpose of preventing accidents by blasting, and which are not at present adopted ?—I do not think that there are. When an accident takes place in blasting I think it is through carelessness, or that the miners have not had proper experience in blasting.

11,058. Do you think that an accident is more likely to happen to a young miner than to another of more experience ?—Very much more likely.

11,059. Why have you not in your mine a man-engine or any improved means of taking the men up and down ?—Our mine is a young mine yet ; we have only got it down to 162 fathoms, and that is no great depth.

11,060. Is it not a great depth for the men to climb ?—No.

11,061. To what depth would the shaft be carried before you would recommend some improved means for raising the men up ?—I should say about 150 or 160 fathoms, if you have a convenient shaft to put it in. We are sinking a sumpt, and we shall have it down to 132 fathoms in the course of two or three months more. We were thinking to increase the area of the old shaft down so far as the 132 to bring up the men.

11,062. How would you bring them up ?—Just the same as the man-engines that have been set up in Cornwall. We can apply stages on the same rod.

11,063. Do you think that that is a preferable mode to the skip ?—Certainly.

11,064. (*Mr. Holland.*) On what rod would you apply the stages ?—The rod that we have working in the shaft.

11,065. The pump rod ?—Yes.

11,066. (*Chairman.*) Why do you not think the skip an available mode of bringing the men up ?—I think it is more dangerous than coming up by the rod.

11,067. Have you ever seen a skip used for bringing up the men ?—No, I never saw it used ; but our men, at the time we were working the old mine at Wheal Vor, used to come up in the skip sometimes, as many as five together in the skip.

11,068. (*Mr. Holland.*) Did any accidents arise from its use ?—Not one in the skip for drawing stones. I came up in it from the 284 one day.

11,069. (*Chairman.*) Was the skip drawn by a chain or a wire rope at Wheal Vor ?—It was drawn up by a hempen rope.

11,070. What was the breadth of the rope ?—It was seven inches wide and a chain attached to the end.

11,071. Were the men allowed to come up in that way ?—No.

11,072. Was it a double skip or a single one ?—It was a double one. I sent down three men there one night after they came up, so as to try to prevent them coming up that way.

11,073. You thought it too dangerous ?—Yes.

11,074. Should you be inclined to recommend your adventurers to go to the expense of a man-engine ?—No, not at present.

11,075. Why would you not do so now ?—We shall have dry rods ; we shall not use them for pumping, but take up the water by the new shaft ; we shall take out all the pumping from the rods we have now in shaft down as far as the 132, then we can apply stages to the present rod.

11,076. What would be the cost of doing that ?—I cannot say ; I have not gone into the calculation.

11,077. Having the rods, it would not be so expensive ?—No, nor near it. We have no other shaft where we could apply it.

11,078. Do you use any kind of patent candles ?—No ; we use the ordinary candles that are going in the country.

11,079. What quantity do you allow to each man ?—2 lbs. a week.

11,080. What do the miners pay for the candles ?—I think it is 8*d.* a pound.

11,081. Have you ever examined the candles to see whether there was any arsenic in them ?—Yes, many times, but I could never detect it.

11,082. What do you think of the noxious smell which arises from the candles, or is there any noxious smell from them ?—I do not think there is much in ours, but there has been in some candles that I have had. I sent up to Bristol some time ago, and I got candles from different parts, and I tried them all, and I did not find any candle that would burn sweeter than our miners' candles that we get in the country.

11,083. Do you mean that they burn with less smoke ?—Yes ; there is less fume arises from them.

11,084. What do you charge the miners for powder ?—8*d.* a pound.

11,085. Is it small-grain or large-grain powder ?—I do not like the very large grain ; a grain about half the size of a pea, or something smaller than that. A mixed powder I generally take.

11,086. With regard to the club money, what do the miners pay to that ?—6*d.* a month.

11,087. What do they pay for the doctor ?—6*d.*

11,088. Is the club money applied only in cases of visible hurts ?—Yes.

11,089. And not for sickness ?—No.

11,090. Is there a separate account kept of the club money ?—Yes.

HELSTON.

Mr. T. Gill.

8 August 1862.

11,091. Do you consider that the club money belongs to the miners or to the adventurers ?—I think it belongs to the men, although a great many men do pay the club money that is indebted to the mine ; they pay it as it were towards the club for a year, having been indebted to the mine.

11,092. Supposing that a mine was stopped, and you had to dispose of any balance of club money, what should you say would be the fair way of disposing of it ?—I should think that the money ought to be divided between the invalids on the mine.

11,093. (*Mr. Holland.*) Whatever the amount might be ?—Yes, because if the men should pay 6*d.* a month, and that should amount to more than what was drawn from the club, their pay should be raised at the time of a serious accident.

11,094. (*Chairman.*) Who would have to provide the money in case the club money was not sufficient ?—Then it would fall upon the adventurers ; but that is a thing that I took pretty good precaution about when I went to Wheal Vor, because our outgoing was more than the incoming, and that should be looked to soon.

11,095. Would you increase the contribution made by the men for club money in order to meet any deficiency, or should the adventurers meet it ?—The adventurers should advance it for a time, it if was a serious accident ; when eight or ten men meet with an accident. At the same time, if you should run down the club, the adventurers should stand by it, but then the men should make it good again afterwards ; it should not come upon the adventurers—not permanently.

11,096. Was it at the old mine or at the commencement of the present mine that you paid the tut-work men once a fortnight ?—That has not been since I have been there.

11,097. Are they always a month in hand now ?—Yes.

11,098. Do you pay subsist ?—No.

11,099. How many doctors are there employed ?—Two.

11,100. How many boilers are there at work now ?—There are seven working now.

11,101. Are there are fixed periods at which you inspect the boilers and clean them out ?—We generally clean them out about once in twelve or six weeks.

11,102. Do you clean them out as often as that ?—Yes.

11,103. Is the water that is used in them bad ?—No, not very bad.

11,104. Do the boilers require to be cleaned out as often as you state ?—Yes, every six weeks where the engine is working five or six strokes a minute.

11,105. It is necessary on account of the accumulation ?—Yes, of the crust inside ; and they are cleaned out so that it shall not get hard in the tubes. I have seen eight tons of stuff taken out of a boiler, the marks of the rivets and the tube being in the crust that has been taken out between the shell of the boiler and the tube.

11,106. Is any record kept of the periods at which your boilers are cleaned out ?—No, I do not think there is, but the books will show that, because we are obliged to pay for cleansing.

11,107. With whom does it rest, with you or the engineer, to say when the boilers shall be cleaned out ?—If the engineer says that such and such a boiler ought to be cleansed out, I tell him to do it at once.

11,108. Is it done on the report being made to you ?—Yes, he generally reports it to me, and it is his place to look after them.

11,109. Have you any means of ascertaining the quantity of water in a boiler otherwise than by the stopcocks ?—No.

11,110. Do you trust to the man who is in charge of the boilers to try those cocks ?—Yes.

11,111. When a new man comes on he must try them too, must he not ?—Yes, it is his place to do so ; and as soon as he takes charge to go through the boilers for himself at once.

11,112. Have you more than one safety valve to each boiler ?—There is only one.

11,113. Are you able to prevent the men from weighting those valves ?—No ; but I do not think the men would weight them ; it is never reported to me. We do not allow the men to change in the boiler-house.

11,114. But I mean the enginemen ?—I do not think that they do but very seldom.

11,115. Has an accident ever occurred with a boiler since you have had charge of this mine ?—Never.

11,116. Have you heard of accidents happening with boilers ?—Yes, many.

11,117. Do you think it is dangerous for the men to change in the boiler-house ?—I should not like to see a large number of men go to change there, for, should the boiler burst, it would be almost certain death to them.

11,118. In paying the men, what proportion is paid in notes, and what proportion in gold and silver ?—We generally pay away about 800*l.* or 850*l.* a month at the mine, and we draw out between 300*l.* and 400*l.* in cash.

11,119. If the men want change where do they go to get it ?—I cannot say where they go for it, but they do not require a great deal ; oftentimes the girls on the floors, if they want to change a sovereign, come back to the office, and the clerk changes it for them.

11,120. Would he change notes for them ?—We give them nearly one half in change, so that they can arrange with each other.

11,121. (*Mr. Holland.*) Is the strength of a boiler always tested when it is bought ?—I think the makers generally test the boilers.

11,122. Do not the purchasers test them ?—No.

11,123. Do they trust to the makers ?—Yes.

11,124. Who employ hydraulic pressure I suppose ?—Yes.

11,125. Are they ever tested again afterwards ?—Very seldom.

11,126. You trust entirely to the first examination ?—Yes.

11,127. If a boiler becomes weak it would be dangerous ?—Yes. I have seen them as thin a sixpence, so that you might take and pick right through them, but they never leaked during the time they were in. I have examined boiler flues many times when we have taken them out, and they have not been thicker than a sixpence.

11,128. Would it not be a great advantage to have the boilers examined properly at short intervals ?—I do not think it would be of great advantage.

11,129. The Commissioners have heard of many explosions taking place ?—They have oftentimes let the feed down.

11,130. That is the chief cause of the bursting, is it ?—Yes. Then the heat forces down the top of the tube, and then the pressure of the steam causes it to collapse.

11,131. A proper examination would disclose any neglect in feeding the boilers. Do you trust entirely to the carefulness of the men in feeding them ?—Yes.

11,132. Is there no feed valve ?—Yes, but then you must turn off the one as you require it.

11,133. Is there no self-acting apparatus to regulate the feed of the boilers, or do you trust entirely to the carefulness of the engine-man ?—It principally rests with him.

11,134. Have the boilers two safety valves, or only one ?—Only one.

11,135. And that valve is entirely under the control of the engine-man ?—Yes.

11,136. He may load it as much as he likes ?—He is not allowed to meddle with it ; but he could do it.

11,137. Would it not be prudent to have one valve out of his reach ?—I do not know. I think that if a man is not to be trusted over a safety valve he is not to be trusted with an engine.

11,138. How does the air pass through the mine ?

HELSTON.

Mr. T. Gill.

8 August 1862.

—That depends upon the strength of the current. Sometimes it is a great deal stronger than at other times. Sometimes it might go through in half a minute.

11,139. In a large mine?—Yes; as soon as you have a reaction.

11,140. What length of time is the air going through the mine?—That I cannot say. It requires some consideration and some study to come at such a matter as that. I cannot enter into that at the present moment.

11,141. Do you consider that cold damp is decidedly different from poor air?—I cannot give a decided opinion on this subject.

11,142. Is cold damp in your opinion more liable to gather in the winzes or in the rises?—I do not think there is so much difference in that; it depends upon how long a level or a rise is kept idle.

11,143. In any case will it gather more in a winze or in a rise?—I do not think there is much difference, that is if there is no current there.

11,144. You have not noticed any?—No.

11,145. You stated, I think, that the decay of timber depends upon the strata in the mine; how can the strata affect the decay of timber?—Because in granite ground oftentimes what we call the dryrot gets in; in dry granite ground more than it does in killas.

11,146. Do you know what the reason of that is?—I do not consider that granite is so damp as the killas.

11,147. You stated that the air in a granite mine was not fouler than in a killas mine?—Yes. In a killas mine sometimes you meet with it. It depends upon how far you extend your levels. I believe from what I have seen you can extend a level to a greater distance in a killas mine than in a granite mine.

11,148. What is the reason of that difference?—That I cannot account for.

11,149. Is it likely to be because you blast more in granite than in killas?—No; in some killas mines you blast as much.

11,150. But you do not generally do so, do you?—Yes.

11,151. Do not you do more pick work in killas than in granite?—I do not think you do so much. Perhaps you may in some mines, but not in those I have been in.

The witness withdrew.

Captain JOHN BURGAN examined.

Capt. J. Burgan.

11,152. (*Chairman.*) Of what mine have you charge?—Treworlis, within a mile of this town, and East Wheal Lovel.

11,153. How many men and children are there employed in those mines altogether?—In one mine there are 70.

11,154. How many men and boys are employed under ground?—Forty-five.

11,155. Then at East Wheal Lovel, what is the number of men and boys employed there?—At present not beyond 40.

11,156. Altogether?—Yes; they are very much reduced there. We have altered our machinery and reduced our hands lately. We had 120 hands a little time ago.

11,157. How long have you had charge of the first of the two mines you have mentioned?—I have been with the present company two years and a half; from its commencement.

11,158. What is the deepest level at which you are driving now?—33 fathoms below the adit, and the adit is 7 fathoms.

11,159. Is it a tin or a copper mine?—There is tin and copper.

11,160. Had you had charge of any other mines before?—Yes.

11,161. In what part of the country?—In this county; Great Wheal Baddern in the parish adjoining Gwennap parish, and another, and Spearne Wheal Mine, near Falmouth.

11,162. Is there any special matter upon which you wish to give any information to the Commissioners?—I do not know but very little about your subject of inquiry, and I do not know that I have anything very special that I wish to speak of.

11,163. Are there any hot levels in the mine where you are working?—No.

11,164. How far are you driving from any winze or shaft at present?—The greatest distance that we are driving is 15 or 16 fathoms from a shaft.

11,165. Is the air at all close there?—It is a little close at the bottom of the level, slightly so. We have a winze now in course of sinking from the level above, and upon the bottom level it is only very slightly close, nothing that any one would complain of.

11,166. Do the candles burn there freely?—Yes.

11,167. How long does the powder smoke hang about?—From 20 minutes to half an hour.

11,168. Are you rising also?—Yes, and sinking to communicate between the two levels.

11,169. Is the closest place in the rise or in the winze?—In the rise.

11,170. How many men have you working in both places?—There are two at a time in each place; that is in the rise and the winze. In the end before the rise there are six men, and there also eight men sinking a shaft again below.

11,171. What do you charge the men for candles?—We charge them 7*d.* per pound.

11,172. What do you charge for the powder?—I think it is 8*d.* a pound.

11,173. What do the men contribute for club money and to the doctor?—They contribute 6*d.* each.

11,174. Is there a separate account kept of the club money?—Yes; entirely so.

11,175. Are the receipts in the shape of club money sufficient to meet the accidents that occur?—We have had no accidents in either of the two mines I have now spoken of. We have been working just six years.

11,176. Do you know what the amount of the club money is?—I do not know; it is a regular company's account; it is not a purser's account nor a club account exactly; it is entirely a company's account, and everything is carried to the credit of the company, as any other matter of business. There will be no difficulty whatever.

11,177. Should the mine stop, would the company then divide it?—Yes, and if it was not sufficient it would be provided without any deduction whatever from the miners. The whole of the money in our mine very nearly is in stock, as far as the club money goes, and that is why we have paid none.

11,178. Have there been any accidents with the boilers?—Not one. I think that there is nothing we ought to be more particular about than the safety of our men.

11,179. Do the men change their clothes in the boiler-house?—Yes.

11,180. Do you think that is a prudent thing?—No; I do not think it is.

11,181. Do you think it is a bad thing?—I think that they ought to have better means.

11,182. You would, I presume, recommend your adventurers to provide a changing-house?—Yes.

The witness withdrew.

Adjourned to St. Agnes, To-morrow at half-past 11 o'clock.

ST. AGNES.

Saturday, 9th August 1862.

PRESENT:

The Right Hon. Lord KINNAIRD, K.T.	RICHARD DAVEY, Esq. M.P.
NICHOLAS KENDALL, Esq., M.P.	P. H. HOLLAND, Esq., M.P.

The Right Hon. Lord KINNAIRD, K.T., in the Chair.

Captain JOHN HANCOCK and Mr. MICHAEL MORCOM examined.

ST. AGNES.

Capt. J. Hancock. Mr. M. Morcom

9 August 1862.

11,183. *Chairman* (*To Capt. Hancock.*) Of what mine have you charge?—Polberro.

11,184. (*To Mr. Morcom.*) You are purser of Polberro mine?—Yes.

11,185. (*To Capt. Hancock.*) What does your mine produce, tin or copper?—Tin.

11,186. Have you sent in a list to the secretary of the men employed under ground?—No.

11,187. How many men do you employ under ground?—94 men and boys on tribute.

11,188. How many on tut-work?—23 men and boys on tut-work.

11,189. How many are there altogether, taking those on the surface?—The total number in the mine is 244. I have a list of the ages of the tut-work men and the tributors, with the average. (*The witness delivered in the same.*)

11,190. What is the deepest level at which you are working?—30 fathoms below adit—the adit is 60 fathoms—that makes 90 fathoms from the surface; the mine is deeper—that is the deepest part of our present working.

11,191. The mine was an old mine?—Yes.

11,192. And you are only working a part of it?—Yes.

11,193. There are several shafts I suppose?—There are eight steam whim shafts at present in use, and five through which the horse whims are drawing, making 13 working shafts.

11,194. Are the levels which you are now working all in communication with the old workings?—Yes, and there are old workings below also; the water is in the bottom part of the mine; we let the water rise to a certain level.

11,195. I suppose that the men ascend and descend by ladders?—Yes.

11,196. Do you know the distance which the steps are apart?—12 inches.

11,197. Do you think that the men prefer the 12 inches to the 10 inches?—We do not hear anything at all about that.

11,198. The ladders are all uniform?—Yes, one foot; we always make our ladders that distance between the staves.

11,199. Is the heat great in any of the levels?—No, it is pretty regular in our mine.

11,200. Have you ever tested what the heat is?—No.

11,201. What are you driving now; are you sinking any winze?—Yes, we are always driving ends and sinking winzes so as to be opening ground for the tributers, and to be proving ground.

11,202. What distance are you now driving from any winze or shaft?—Perhaps the furthest off is 60 fathoms from shaft; one end.

11,203. How far from a winze?—Perhaps 25 fathoms.

11,204. Are you sinking a winze at the end of that 25 fathoms?—No, we are now going to start a rise from the present end of 25 fathoms.

11,205. Is the air at all close at the end?—No, it is very good indeed, we have pipes to carry in to blow away the smoke from the men.

11,206. By means of a boy at the end?—No, there is a trap door, and there are air pipes.

11,207. From another level?—From a level above.

11,208. How long is the smoke getting away?—They can go into the end in five minutes after they have fired the hole.

11,209. So that by trap doors you conduct a current from other levels down to the point where you are working?—Yes, by a trap door and pipes.

11,210. Do you use any other means for forcing in air?—Yes, we blow a machine occasionally, if we find it necessary, but that is very seldom, we have so many shafts that it is not required.

11,211. By a proper management of trap doors and pipes you can conduct the air to any part of the mine?—Yes, we have very good air indeed throughout our mine.

11,212. Have you ever seen anything of the cold damp?—No, not in this mine.

11,213. Have you ever yourself worked in or been connected with a granite mine?—Yes, I have had a great deal to do with granite mines.

11,214. Do you think that they are more subject to cold damp than the killas?—Yes.

11,215. Have you seen cold damp?—Yes, the cold damp in the granite more especially than in the killas, and of course the men complain more of it in a general way.

11,216. How do you judge of cold damp?—After perspiring pretty much and sitting, we find that we get very cold, and our clothes clammy and wet and cold, the men feel very uncomfortable in it, more so than if working in killas.

11,217. With regard to cold damp do you judge by the candles?—No, I never observed it make any difference in the candles.

11,218. Have you ever worked in a close end?—I have never worked in a close granite end, but I have had to do with it a good deal.

11,219. What is the effect upon the candles in a close end?—Of course you require to touch a candle up pretty often, and to put it on a certain angle, and to snuff it often.

11,220. But that is not the case in cold damp?—No, I have never seen any cold damp which would have that effect.

11,221. Have you ever seen when the men have not been working in any winze, or at any end, that the candle would go out?—Yes, many times; and I have kept the candle before me, and I have gone so far as that the candle has died out, and then I have kept back. When we find it like that we of course use means to put air in before the men go in.

11,222. Might not this have been equally the case if the men had been working there?—No.

11,223. If the men had not been working there how would you manage?—If you carry a good strong breeze of wind through pipes, or some other means you get rid of it. I have known places which have been communicated, say, for instance, an end, when we could not get into that end; and after communicating a winze with that end we could see the damp, it would affect the light in the winze as it was escaping through the place which was communicated

11,224. When you have connected a winze with a level where this bad air has been have you seen the effect of it?—Yes, upon the candle.

11,225. But have you been able to see anything in the shape of vapour?—No; I do not know that I ever discovered anything of that sort. I have seen it upon the bottom of a winze or close in an end, and we have seen it form like a mist, that we have seen repeatedly; and sometimes in dropping a candle down in a winze we have seen it like a smoke, and the fire is out of the candle in an instant.

11,226. Have you had any accidents from blasting lately?—We have had one.

11,227. Were you able to ascertain how it happened?—Yes, by tamping a hole.

11,228. What with?—With an iron tamping bar.

11,229. Was proper tamping put in?—I think it was a very careless job; it was a shallow hole, and there was very little powder in it. I believe that the hole was not more than a few inches deep, and I believe there was not more than an inch or two of powder, and the man did it pretty quickly and thoughtlessly; and the hole went off in tamping. The hole did not bring out the burthen.

11,230. Had the man put in the proper tamping?—They said that they had proper tamping; it was evidently carelessness.

11,231. It must have been occasioned I suppose by the iron tamping bar striking and creating a spark?—Yes, it must have been that.

11,232. Might it not also have been that there was some powder left on the edge in filling in?—I asked the men about the matter, and they said that they could not tell; only that it exploded in tamping.

11,233. Do you imagine that you could set the powder on fire by the mere force of tamping if there was any vacant air in between the tamping and the powder?—No, I think not.

11,234. If a hole explodes after the third or fourth tamping, how would you account for it?—I have never known an instance of that sort. I have known several holes explode in the first and second laying of the tamping, but never in the third or fourth.

11,235. In the second tamping it might arise from the tamping bar striking against the edge?—In my opinion it is from striking fire by careless tamping, before the powder is properly cleaned out.

11,236. Have you ever seen a cartridge used?—Yes, when they are rising frequently, but not in any other holes; that is for the purpose of putting the powder in properly; that is the only cartridge which we use.

11,237. Are the gettings in this district of St. Agnes less than in other districts?—No, we are paying more wages than they are in other districts.

11,238. (*Mr. Holland.*) What are the usual earnings per month?—The average wages of our tributers are more than 4*l.*

11,239. Net or gross?—Clear to them.

11,240. (*Chairman.*) Has the amount risen lately?—No, it has been like that for a good while, for perhaps the last four or five years.

(*Mr. Morcom.*) Yes, before that they were much lower.

11,241. (*Mr. Holland.*) (*To Captain Hancock.*) Why are they higher?—There is not competition sufficient in the labourers; there are few hands in the district, and nobody will come out here, except those who are born and bred here.

11,242. (*Chairman.*) Why will not hands come from a distance here?—I can hardly account for it any other than that the mode of working being so peculiar, many of the lodes being so flat that strangers require some time to get acquainted with it.

11,243. Have you house accommodation for them?—Very good accommodation.

11,244. Sufficient accommodation?—Yes, and the men are better off here I think than anywhere else. I have no doubt that they are.

(*Mr. Morcom.*) I suppose that one reason is that the miners in the south do not understand our mode of working.

(*Capt. Hancock.*) It is a peculiar principle.

11,245. (*Chairman.*) You say that there are more tribute men than tut-work men?—Yes.

11,246. How is the ground set to the tribute men?—So much in the pound.

11,247. On what principle is the mine worked?—The mine is worked principally on tribute.

11,248. From the peculiar character of your lodes you are obliged to have men experienced in the work?—Yes.

11,249. A stranger would not have the same advantage as a tributer here as one who is acquainted with the mine?—No. Of course a stranger now and then comes round and falls in with these men, and we hold them as well as we can.

11,250. (*Mr. Davey.*) Where you can get a stranger to join pairs?—Yes.

11,251. (*Mr. Morcom.*) But if he was on his own account he would never get on.

11,252. (*Chairman.*) (*To Capt. Hancock.*) How many boilers have you at work?—We have three to the drawing engine, and we have four boilers to our stamp engine, and we have two whims with two a in each, so that we have nine working boilers.

11,253. Do you clean them at any stated period?—Yes; we clean about an average of three every month out of the nine, you may say three of boiler eight; as one of the whims is not employed much.

11,254. (*Mr. Holland.*) So that they are cleaned about once in three months?—Yes.

11,255. (*Chairman.*) Is the water good?—It is very bad.

11,256. (*Mr. Holland.*) In what respect?—It is principally sulphuric acid.

11,257. (*Chairman.*) And it corrodes?—Yes, very badly.

11,258. And does the machinery suffer?—Yes; we use brass in most places where the water is acting powerfully upon it, where we can do it, and the gauge cocks are silver.

11,259. Is this water of the same character as that which you pump out of the mine?—Yes; that is the water which we have; we have no other water than what we pump out of the mine for every purpose, except rain water; we are careful to catch all we can as it is much better for the machinery. If we have an iron air-pump bucket rod 3½ or 4 inches, it will not stand more than a week or a fortnight.

11,260. What has been your experience of the effect of the water on a chain which had been in the lift of the pumps for five weeks?—The links were entirely separated and were reduced more than one half of their size. It was destroyed by the sulphuric acid.

11,261. Are you not afraid of your boilers exploding?—No, we are never concerned about it; we pay great attention to that. We must of course examine the cocks very often and pay great attention to it.

11,262. Have you ever had a boiler explosion?—No.

11,263. (*Mr. Holland.*) How long will a boiler last?—They are so repaired that one can hardly tell; but one new boiler will probably last about two years without repair.

11,264. What is your explanation of the boilers suffering so much less rapidly than the pumps?—Because the water is rapidly passing through the pumps. I have been 14 years in the mine, and some of the pumps are there now, whereas in some other places we have changed three or four pumps.

11,265. Is the chief action of the water upon the pumps contracting the bore?—Yes; it destroys the iron also. Sometimes some of the corrode will fall away and it will work a hole through the iron.

11,266. How long do the pump pipes last?—If there was no corrode about them probably they would last four or five years or three or four years, it depends upon the casting. We have perhaps changed some of our pumps twice in the year, and in another case it will last seven or eight years.

11,267. Do they last two of three years on an average?—Yes; more than that.

11,268. Would it not be a very important thing for you to be able to protect the pump?—Yes, but I can hardly tell how to do it to be of much benefit.

11,269. Have you noticed that the water injures the miners at all?—No; we do not hear of any complaint from the miners about it.

11,270. I notice in your return that almost all your

St. Agnes.

Capt. J. Hancock. Mr. M. Morcom.

9 August 1862.

tributers are below 40 ; only 19 out of 94 are above 40 ?—Yes.

11,271. What becomes of the men above 40 ?—A great many of them go away upon the burrows picking a little tin, and a great many of them have help from their friends and retire. There are a great many old men in the parish.

11,272. Do not a great many of them die ?—Yes, of course they die.

11,273. At what age do you look upon a miner in this district as an old man ?—I can hardly tell. A great many men in this district are between 60 and 70, (I mean not working but living here). I hardly know what has become of many of the old men.

11,273*a*. What becomes of them when they get above 40 ?—I do not know, it requires a little time to inquire into that matter. I do not know that any of our men die before they are pretty old.

11,274. Of the 23 tut-work men there are only 6 above 45 ; what becomes of the others ?—I do not know. I do not know how to explain it. I do not think that it is very easy to explain it, as we have had very few deaths below that age "45."

11,275-6. (*Mr. Davey.*) Have not a large number of them small cottages and tenements of their own ?—That is what I meant to say ; they fall back from mining and go upon the burrows, and so on.

11,277. In which they occupy their spare time ?—Yes ; a great many of them.

11,278. And I suppose that some of them get into small shops after they have made a little money ?—I can hardly tell about that. There are perhaps some, but not a very great many.

11,279. Formerly there was a reason why St. Agnes men did not get so much as at other places, because nine-tenths of them had little tenements where they used to work all their spare time, and consequently worked less time at the mine ?—Yes ; I have heard that ; but there are pretty many of those now in the district. They fall back from the mine and get their living in some other way. There are more old men here going about in other ways than in any place that I know.

11,280. (*Mr. Holland.*) Do they consider mine work unfit for a man above 40, and do they therefore leave it ?—No ; I do not know that they do.

11,281. Why do they leave the employment when they are above 40 ?—Many of those men have children, and they bring them up to work with them, and when they get into those pitches up here, it being a peculiar mine for working, they get more money than anywhere else, and they leave work sooner than anywhere else. They have their children, and so on, to help them, and they take their tenements and live upon these little places, and there is more independence here than in any other place that I have seen. They get as independent here as members of Parliament in a little while.

11,282. (*Chairman.*) I suppose that a man after a certain age does not particularly like climbing the ladders ?—After a certain age they would not do it. They seem to drop back in the way that I have stated. That is the only way that I know.

11,283. Within your certain knowledge are there a great many who get farms ?—Yes ; great numbers have fallen back in that way since I have been here, and there are numbers living about now.

11,284. Can they earn more in that way than by working in the mine ?—Not so much I suppose ; but then they do not require so much, and they have their children to help them.

11,285. Their children work in the mines ?—Yes; and the parents stay at home. I think that there are more old men living about here who were miners than at any place that I know of.

11,286. But they do not work in the mines here ?—No.

11,287. It is your opinion that they can get occupation out of the mine without any difficulty after they come to a certain age ?—Yes ; in the way that they do now.

11,288. Do they rent these small farms ?—Some of them take them perhaps when they are unable to work, and they build a little cottage and take in a few fields, and then they have that to fall back upon.

11,289. Would those men return themselves in the Census as miners or as farmers ?—I suppose as farmers. They would not return themselves as miners.

11,290. I have a return of the number of accidents which have happened in mines, and among others it says, "Killed by a fall from one level to another; "from the 50 fathoms level to the 150 ;" what does that mean ?—That is falling through the shaft from one level to another. If they fall away from the 20 fathom level they fall perhaps to the 30 or the 40 fathom level, and there they stop.

11,291. Is it in climbing mostly ?—Sometimes ; and sometimes perhaps they may be knocked away by the kibble in the shaft. Kibble fillers I think are more killed in that way on the average; they are more exposed than miners. We have been at Polberro 14 years, and I think that we have had four men killed, and two of them have been kibble fillers.

11,292. Do you use a kibble or a skip for drawing ?—Both.

11,293. Which do you find most economical for drawing ?—If we had good shafts we should prefer the skip, but our shafts are bad shafts generally speaking. They were not sunk by us ; they are perhaps hundreds of years old.

11,294. And you think that you could not apply the skip to them ?—No ; it would be too much expense in applying timber.

11,295. (*To Mr. Morcum.*) Do you use any particular kind of candles, patent candles ?—No, not patent candles, but the best that we can get in the county. We get ours from Penzance.

11,296. What are the men charged for the candles ?—We charge the men 9*d.* a pound for them.

11,297. How much a pound do you charge for powder ?—The same price.

11,298. Do you use the small grained or the large grained powder ?—The small grained generally.

11,299. Is it preferred by the men ?—It is by our miners because it is dry ground. There is very little water.

11,300. Is there a charge for the barber in your mine ?—No.

11,301. How much is charged for club and doctor ?—Sixpence a month for the club and sixpence for the doctor.

11,302. Do you keep a separate account of the club money ?—Yes ; quite distinct.

11,303. Is a statement of that account rendered to the adventurers with the other accounts ?—No ; not exactly to the adventurers, but to our managers in London.

11,304. The club money is for visible hurts, I presume ?—Yes.

11,305. Do you consider that as belonging to the men or to the adventurers ?—To the adventurers.

11,306. Have you a large sum at the credit of the club account ?—Yes. At the present moment we have somewhere about 700*l.*

11,307. And the adventurers, according to your opinion, would be entitled to apply that money to any purpose in the mine ?—Decidedly ; for this reason. Many years ago I was in Gwennap, and we had a great many accidents, and every now and then we had to charge to the cost book 50*l.* deficiency in the club, and therefore it must belong to the adventurers.

11,308. But I suppose that that was made up again ?—Never. That was done repeatedly.

11,309. That is not your case ?—No.

11,310. Therefore you have not so many accidents as they had at Gwennap ?—I never knew less accidents than we have at Polberro.

11,311. And therefore your fund accumulates ?—Yes.

11,312. Of course a large charge coming against

ST. AGEES.

Capt. J. Hancock. Mr. M. Morcom.

9 August 1682.

the club shows that there must be a good many accidents?—Yes.

11,313. How many doctors have you?—Two.

11,314. Are they appointed by the adventurers?—Yes.

11,315. Have the men anything to say in the appointment of the doctors?—Yes; I think they have. We should not appoint a medical man if the men were opposed to it.

11,316. How would you ascertain that?—Soon after I came to Polberro there was an objection made by the men to having doctors from Redruth. They were old respectable medical men from Redruth, but the distance being so great, and there happening to be a medical man residing in the place who had nothing to do with our mine and who was a great favorite with the working men, they petitioned to have him appointed, and our managers in London agreed to it.

11,317. Is it desirable to have a medical man near to the men in case of accident?—Yes; we have both in the village, and they are very attentive.

11,318. I suppose that a doctor residing at a distance would be obliged to employ an assistant, or would the men have to go to him?—They would have to go to him. In fact they escape a great deal of the work by living at a distance; it falls on the medical man living on the spot.

11,319. Whether he is employed by the mine or not?—Yes; it is not worth their while to go five, six, or nine miles.

11,320. Do they, living at that distance, receive the 6*d.* per man?—They do in many cases. There is a great deal of interest in being appointed medical man to a mine.

11,321. Does a medical man get shares in a mine and canvass for the appointment?—Not to my knowledge. Sometimes the lord of the soil in granting a set will stipulate to have his own medical man; that is very often the case.

11,322. What proportion of notes and of change do you get from the bank when you pay your men on the pay-day?—In notes, perhaps one half. In paying the children I always take care to pay them in change, so that they may have the money and go to their homes as quickly as possible; but tributers may have to receive 10*l.*, and then they may as well have notes as otherwise.

11,323. In the case of the men how do they get the money changed?—I am afraid that in nine cases out ten they go to the publichouse.

11,324. (*Mr. Holland.*) You have stated that there is a considerable excess in the proceeds of the club?—Yes.

11,325. Then more has been charged to the men than in proportion to the risk which they have incurred?—Yes.

11,326. Is that quite just?—Yes; I should say quite, for this reason, I consider that the adventurers are really that out of pocket; the adventurers pay it. In employing the men you do not really deduct the doctor and club out of their money. They must have a certain sum to take home to maintain their families and we should screw them a little tighter so as to save the amount of the club money.

11,327. Is there any complaint of it by the men?—None at all. In fact I have not heard a single complaint by our men; they do not know the state of the club at all. If we had to pay them double what we keep back from them they would get the money.

11,328. You said that you had two doctors; have the men a free choice of which doctor they will go to?—Yes.

11,329. Does the doctor who has most patients get most pay?—No; one doctor takes one month and the other doctor another to attend to any new patients who may come on. They go on with the old patients. If any of the men prefer one or the other they go to him although it is not his month.

11,330. And do the doctors divide the payment equally between them?—Yes.

11,331. Would it not be an improvement if the doctor who had the most patients had the most pay?—No; I should not fall in with that myself.

11,332. What do you think would be the objection to that?—In the first place there would be a difficulty in getting at a correct statement how it stood you need keep a clerk to keep the accounts.

11,333. What other objections to it are there besides its complicating the accounts?—I am afraid that if it was left to the men entirely there would be some canvassing.

11,334. Do you fear unfair rivalry between the doctors?—I have noticed in different districts that wherever there is a drinking good for-nothing doctor he is sure to be popular with the lower orders, if he will go to the publichouse and take his pot of ale with them. Of course they cannot judge whether he is a clever man or not.

11,335. (*Chairman*). Are there any such characters as that among doctors?—Yes, I have known them.

11,336. (*Mr. Holland*). Does any other objection occur to you?—No. I wish to give an explanation with respect to what has become of the old men. In the first place, I suppose that three fourths of the working men in this parish have money accumulated in the savings bank, they are continually paying into the savings bank; there is very little drunkenness here, less than in any place that I know, and they put a great deal of money into the savings bank. There are not so many families as appears by the list of names. There is a father who has perhaps two or three sons working with him; a great many of them in this neighbourhood have little leasehold places, and they have money in the savings bank; they have saved up money to buy perhaps a cow or two, and when they get up about 40 years of age, they purchase a horse and pick up their living in many ways and cease to be miners.

The witnesses withdrew.

Captain JAMES NICHOLAS examined.

Capt. J. Nicholas.

11,337. (*Chairman*). Of what mine have you charge?—Huel Kitty (St. Agnes).

11,338. Any other?—No.

11,339. Have you a list of the number of men?—I have. (*The witness delivered in the same.*)

11,340. Is your mine tin or copper?—Tin and copper, principally tin.

11,341. How many men and boys are employed underground?—119.

11,342. How many altogether are employed, including those on the surface?—I do not know.

11,343. Are the men chiefly on tribute or tut-work who are employed in your mine?—There are 41 men on tut-work, and 23 boys; 46 men on tribute, and 6 boys.

11,344. Do the men ascend by ladders?—Yes.

11,345. Do the ladders follow the lode?—We descend perpendicularly until we reach the lode, and then we walk down over it, it being so flat.

11,346. What is the deepest level at which you are working now?—The 100 fathom level under adit, the adit being 45 fathoms.

11,347. How many men are working on that level?—8 men and 2 boys at the 100 fathom level.

11,348. At what level are most men working?—At the 54 fathom level, west of Holgate's shaft.

11,349. How many men are working there?—30 men and boys.

11,350. Are you sinking a winze or putting up a rise?—We are putting up a rise at the back of the 54 fathom level to communicate with the 44 fathoms level.

11,351. Are you sinking a winze or putting up a rise at any other place?—We are putting up a rise at the 100 fathom level.

St. Agnes.

Capt. J. Nicholas.

9 August 1862.

11,352. At the 100 fathom level how far are they from any winze or shaft?—25 fathoms from a winze, we are putting up a rise at that point.

11,353. Is the air close at all there?—The air is not close, but the smoke does not go away quick enough, and we shall not be long before we get a communication.

11,354. How long is the smoke getting away?—From a quarter to half an hour very likely.

11,355. How long do you think you shall be before you get a communication with the other level?—About two months.

11,356. (*Mr. Kendall.*) How many men work in that end?—Six men in the end, and two men and two boys in the rise.

11,357. (*Chairman.*) Have you any night cores?—Not in the rise, but we have in the end.

11,358. In the 50 fathom level, what are you at work at, are you sinking?—We are driving both east and west from a cross cut, it is what we may term a new lode, and we are driving east and west, and also putting up a rise on the back of that level.

11,359. How far is that rise from a winze or shaft?—About 10 fathoms from ventilation.

11,360. I suppose that in all those ends a candle would burn perfectly?—Very well.

11,361. Although there are a great number of men working in a small space?—Yes, more than there are anywhere else.

11,362. And you do not find the air at all bad there?—The air is not bad, but the smoke lies a little.

11,363. That is the only inconvenience which the men experience there?—Yes.

11,364. Have you any artificial mode of ventilation?—Yes, an air machine.

11,365. Where is that applied now?—At the 54 fathom level; at the same place as we are now speaking of we have an air machine 14 inches wide by 7 inches high within, and from the end of the large pipe we have two split pipes, one in the western level and another in the rise, and also one to send air into the eastern level.

11,366. Is that kept working during the whole three cores?—Yes.

11,367. By hand?—Yes.

11,368. Have you three boys employed?—We have two boys in the one core, when there are more tributors there, and one boy in each of the other two cores, making four boys.

11,369. Then the two boys take it alternately?—They keep it going the whole time during which the men are at work.

11,370. Has there ever been any accident since you have been at Huel Kitty?—Two.

11,371. Arising from what?—A piece of ground turned out from the side of a level and fell on a man's foot, and he became jaw-locked. In the other case, a little boy came in contact with the rods of the engine shaft; he was coming up.

11,372. Have you had any boiler explosions?—None.

11,373. What do the men pay for candles?—8*d.* per pound.

11,374. And what for powder?—8*d.*

11,375. And for club money and doctor 6*d.* each?—Yes.

11,376. Is a separate account kept of the club money?—Yes.

11,377. Do you know the amount of the credit of the club money?—I do not.

11,378. Is there a charge for the barber?—There is a barber there for the first month; we have not charged yet, but we are thinking of doing so.

11,379. Is the water bad for the boilers?—It is bad, but not so bad as it is in some mines; a boiler stands about 10 years.

11,380. How often do you clean them out?—About once in six months.

11,381. Whose business is it to examine the boilers?—That belongs to the engineer.

11,382. The captains have nothing to do with the boilers?—No.

11,383. In cleaning out the boilers, is there much sediment, or are they corroded by the water?—There is a sediment, and that of course comes from the corroding which eats out from the boilers.

11,384. How do you ascertain the quantity of water?—By stop cocks.

11,385. Have you more than one safety valve to your boiler?—Only one.

11,386. Is the strength of the boiler ever tested?—No, that is tested before it is brought into the mine.

11,387. But not afterwards?—But not afterwards.

11,388. I suppose that as a captain you pay great attention to the ladder ways and underground works, being in good order?—I pay great attention to everything belonging to the mine.

11,389. Does the timber rot at all in your mine?—In one level there is a little dry rot, but not much.

11,390. Is attention paid to the timber being removed from the levels?—No timber is removed from the levels.

11,391. When it rots and falls away what becomes of it?—If it is not worth anything we send it away to the surface and put in new timber instead. None is taken out so as to injure the levels.

11,392. Is attention paid to keeping the levels clear of decayed timber?—Yes; we have very little of that in the mine.

The witness withdrew.

Captain William Higgins, of Penhall's Mine, St. Agnes, examined.

Capt. W. Higgins.

11,393. (*Chairman.*) Are you captain of Penhall's mine?—Yes.

11,394. Have you a list of the men employed there?—Yes. (*The witness delivered in the same.*)

11,395. What is the deepest level at which you are now working?—40 fathoms under the adit.

11,396. Is the air quite good where all your men are working?—Very good all through our mine.

11,397. How many boilers have you?—Two.

11,398. How often are they cleaned out?—About once in nine months.

11,399. Do you find that the water very much corrodes the iron?—Not much; we get pretty good water.

11,400. What is the effect of the water on the iron?—We do not find it affects the iron much; when the water has been heated it affects it more.

11,401. Does it affect the pumps at all?—No.

11,402. Then the water is good?—The water is good as far as we have seen of it; we have now been working five years and we find it eats very little.

11,403. Have you ever worked yourself in a close end?—Yes.

11,404. In what mine?—In Huel Coates, and in Wood mine.

11,405. What is the closest end which you have ever worked in?—It was in Wood mine.

11,406. What was the effect which you felt there from working in close air?—It left an effect upon the chest and lungs; for four months after I gave up there I was not able to work.

11,407. What level was that?—20 fathoms under the adit.

11,408. How far from any winze were you working?—132 fathoms, I think.

11,409. Were you driving at that distance?—Yes.

11,410. Had you any means of ventilation?—Air sollars.

11,411. Do you think that that was sufficient ventilation?—No.

11,412. (*Mr. Kendall.*) Had you no fan?—No.

11,413. Did you entirely depend upon sollars at 132 fathoms distance ?—Yes.

11,414. How high were your sollars ?—About two feet.

11,415. Above or below ?—Below.

11,416. (*Chairman.*) Did you ever work where you had to throw lime in before you went in to work ?—No.

11,417. You have heard of that being done ?—Yes, many times.

11,418. How long were you working in the close end which you have just mentioned before you were obliged to give up ?—I worked in that place seven months.

11,419. How many others were working there ?—There were only two of us.

11,420. Did the other man suffer also ?—Yes, he only lived two years afterwards ; he was laid up at once.

11,421. (*Mr. Kendall.*) How long was it before you felt ill ?—It was two months before I felt it hurt me, but we were engaged at a pay to carry on, and we carried on for five months afterwards.

11,422. (*Chairman.*) What extra pay was given ?—I was then a boy about 16 years of age, and was allowed to get 3*l.* 10*s.* a month.

11,423. Did you ever complain ?—We complained of the air; we did not like to stay there, but were told that we should get along, for that they wanted to drive a cross cut to prove a lode a little further to see whether it would be productive or not, and that if so they would put down a shaft.

11,424. (*Mr. Kendall.*) How far from the surface were you working ?—About 50 fathoms.

11,425. And therefore they did not like to go to that expense till the lode was proved ?—No.

11,426. (*Chairman.*) You worked in the Gwennap mines for some time, did you not ?—Yes.

11,427. In your opinion, did you suffer from working there ?—No.

11,428. How long did you work there ?—About three years.

11,429. And you were never the worse for it ?—I was never the worse for it.

11,430. Do you think that you are now quite strong and well, or do you feel the effects of it ?—I feel the effects of it now if ever I take cold.

11,431. (*Mr. Kendall.*) You say that when you were working in this end, 132 fathoms from any shaft, you felt poorly at the end of two months ?—Yes.

11,432. And you knew that the air was doing you harm ?—Yes.

11,433. But still, as you were encouraged by this high pay, you went on ?—Yes.

11,434. (*Chairman.*) Why did you give up working in the Gwennap mines ?—I chose to have my work nearer by.

11,435. How long have you been employed as captain ?—18 months.

11,436. (*Mr. Holland.*) How old are you ?—40.

11,437. How long have you had anything the matter with your chest; ever since you were 16 ?—Yes.

11,438. Have you a tender chest now ?—Yes, a little when I have a cold.

The witness withdrew.

Captain John Prout Daw examined.

11,439. (*Chairman.*) Of what mine have you charge?—Tywarnhaile.

11,440. Any other mine ?—No.

11,441. What does your mine produce ?—Copper.

11,442. No tin ?—No tin.

11,443. How many men have you ?—We have 120 underground, we have 100 at the surface dressing, that is the dressing pair, and we have 18 men employed on the surface, carpenters, smiths, enginemen, &c.

11,444. Is your mine an old mine ?—An old mine.

11,445. What is the greatest depth of level at which you are now working ?—Ninety fathoms from the adit.

11,446. And the adit is how much ?—Forty-five fathoms.

11,447. Do the men ascend and descend by ladders ?—Yes.

11,448. How many levels are you working on now ?—We are working every level; that is to say, every ten fathoms.

11,449. What is the greatest number of men on any one level ?—About 30.

11,450. That is in different corps ?—Yes.

11,451. Do you work three corps ?—Our mine being chiefly worked on tribute the men work the greater part by day.

11,452. What is the proportion of tribute men to tut-work men ?—The number of our tut-work men is small ; we have only 24 tut-work men, and the others are on tribute.

11,453. Are the tut-work men driving a level or sinking a winze, or putting in a rise ?—One pair of nine men is dropping away and forking the water under the 90 fathoms. The other men are sinking a shaft, and six men are driving an end.

11,454. Is the air quite good in all those levels ?—Yes.

11,455. Have you seen where a candle would not burn in the mine ?—No.

11,456. Have you ever yourself worked in a level where a candle would not burn ?—No; although I have worked where it was poor air.

11,457. How do you know that it is poor air if the candle burns ?—We are obliged to turn it on one side. It will not burn upright.

11,458. That you call poor air ?—Yes.

11,459. If the candle went out what should you call it ?—We should call it very bad ; we should not like to stay there.

11,460. But there is no place in your mine where the candle has to be put on one side in working ?—No.

11,461. Have you any artificial means of ventilation ?—No.

11,462. How do you take the air into an end when they are driving an end or sinking a winze ?—It goes in naturally, our mine being well ventilated.

11,463. What sized levels do you carry ?—Our levels are about eight feet high and five feet wide on an average.

11,464. How far should you consider it safe in order to secure good air to carry a level from any winze or shaft ?—I think 50 fathoms.

11,465. Without any artificial means ?—Without any artificial means. That is in Tywarnhaile, although in some places you are obliged to put in timber. Timber is a thing which will eat up a great deal of air, and there you could not go so far. Where the ground is soft and you have to keep the levels abroad through timber you cannot go so far as where you are driving a high and wide level in hard ground.

11,466. Does the timber decay at all ?—No ; our water rather preserves it than decays it.

11,467. Then you have no decaying timber ?—We have no decaying timber in Tywarnhaile.

11,468. How long have you had charge of this mine ?—I have been in the mine now about ten months.

11,469. Have you had any accident during that time ?—No. In fact, since the mine has been in work by the present company, which is about three years, they have had no accidents of any serious nature.

11,470. What do the men pay for club money ?—6*d.* a month.

11,471. Is a separate account kept ?—Yes.

11,472. Have you seen that account ?—Yes.

St. Agnes.

Capt J. P. Daw.

9 August 1862.

11,473. Do you know about how much is on the account now ?—I think that we have something like 40*l.* on the account now to the good of the club.

11,474. Have you any pensioners on the club ?—No; not having any accident and our mine being well ventilated we have scarcely any men home.

11,475. I suppose it is only for visible hurt ?—For visible hurt, except in cases of great distress, where we have the chance of giving a man anything which we might think proper from the club. That is a rule of the company.

11,476. Who would feel themselves at liberty to do that ?—The agents.

11,477. Do the men pay the barber ?—No.

11,478. How many doctors have you ?—We have three.

11,479. What are the men charged for candles ?—8*d.* a pound.

11,480. And how much for powder ?—8*d.*

11,481. Is the water good for your boilers ?—It is what we call pretty good for this county; not very good.

11,482. How often do you empty and examine the boilers ?—Every three months.

11,483. Does much corrosion go on ?—Not a great deal. We keep that department pretty well looked after.

11,484. Is it the business of the captains to see that the boilers are attended to ?—No; it is the duty of our working engineer.

11,485. Have you anything but stop cocks to ascertain the quantity of water ?—We have glasses which indicate the quantity of water in the boiler.

11,486. Do you think that a good thing ?—A very good improvement.

11,487. From a return which I have I see that several accidents happen in the mines, and that a great many persons are killed by a fall from one level to another; how does this happen ?—Sometimes through carelessness.

11,488. Where does a man fall; is it in the shaft ?—In the shaft, and sometimes in winzes sunk from one level to another. You may have ever so good a footway but you will sometimes find that men, and especially young men, race, and they will sometimes throw away one of the others, and sometimes they will take up too great loads and carry them from one level to the other, which they ought not to do. Our men have no reason to carry down anything; our skips are open to carrying anything which they require. Sometimes men fall from one level to another through winzes, and where there are very good ladder-ways.

11,489. There is no protection put at the mouth of the winze ?—We cannot put any protection at the mouth of the winze.

11,490. If a candle went out and a man had no means of lighting it, how would he get up from a low level ?—They have now generally matches.

11,491. But suppose that the matches got wet ?—If they were not well acquainted with the road their better way would be to stop where they were till some person came along; some person generally comes along every hour or so.

11,492. They would not be safe without a light ?—No.

11,493. (*Mr. Holland.*) Do you not sometimes go along the levels without a light ?—You may do so, but sometimes there are sinks and you get deceived by going in the dark.

11,494. I saw a man going along a level on his hands and knees without a light; is that a common thing ?—No.

11,495. (*Chairman.*) I suppose that a man would sooner go on his hand and knees than stay two hours ?—He would.

11,496. (*Mr. Holland.*) You said that there were no means of protecting the winzes which were left open; could not a grating be put over them without interrupting the ventilation ?—I think not. I think that that would injure the ventilation.

11,497. It would stop the ventilation very little; they are in coal pits ?—Our drivages and sinkages are rather small compared with what they are in coal pits.

11,498. A coal pit has a much greater current of air than you have ?—Then the gases are much stronger.

11,499. Is there any objection except the expense ?—The expense of it would be a mere trifle, because we could generally soller over a place which would take a man through.

11,500. I do not mean sollering, but I mean that a grating or a fence might be put round ?—When you go down a mine generally that winze is sollered over more than where the ladder is to take a man through. The expense of a few boards on the edge there would be nothing, so that it cannot be on account of the expense.

11,501. (*Mr. Kendall.*) In many places where the winzes are you ascend and descend by ladders; you could not put gratings over those without the trouble of removing them every time ?—No, you could not.

11,502. Is there any danger with ordinary care ?—No.

11,503. Might not a man go ten thousand times without any accident if he was moderately careful ?—Yes.

11,504. You often put a plank a few inches wide, and the men would fall if they slipped, but there is no danger of their falling ?—No.

11,505. If the light goes out they should wait till they get another light ?—Yes.

11,506. And if they run any risk it is their own fault, they should not do it ?—Just so.

11,507. But with ordinary and common care the winzes and shafts are not dangerous ?—Not with ordinary and common care.

11,508. Have you ever known an accident of that kind happen underground where common care was used ?—I do not know that I have; where accidents have happened, some I have seen have been through carelessness, and I have heard other men say that if they had used a little more care it would not have happened.

11,509. (*Mr. Holland.*) Did you ever know an accident either above ground or below except from carelessness ?—I do not know that ever I did.

11,510. (*Chairman.*) Besides winzes, when you find a bunch of ore do you not drive down ?—Yes; if we find a bunch of ore we drive on the level, and sink down after that; there are many sinks made by the tributers in stopeing away the ground, which would be equally dangerous with the winzes, and more so.

11,511. In an old mine there are many footways and shafts which are abandoned, are there not ?—Yes.

11,512. Are those always protected ?—We look after that very closely.

11,513. Do you think that that is generally done ?—I am sorry to say that it is not. I could point out many instances where it is not done.

11,514. And that of course causes great danger ?—Yes.

The witness withdrew.

Captain John Taylor examined.

Capt. J. Taylor.

11,515. (*Chairman.*) Of what mine have you charge ?—Wendron Consols.

11,516. What kind of ore does that mine produce ?—Tin.

11,517. You have sent in a list of the number of men employed underground ?—Yes.

11,518. Do you know generally how many persons you have altogether in your employ underground and above ?—About 360 I think.

11,519. What is the depth of your deepest level at which you are working ?—90 fathoms.

11,520. Have you charge of any other mines ?—No.

11,521. What means have the men of going up and down; is it by ladders?—All by ladders.

11,522. How many men have you driving any one level?—We have six men, that is the most in any one end. On a level we have as many as 12 men, namely six at each end, six east and six west in the same level.

11,523. Driving from the shaft east and west, that is to say, two at a time in each end, making four?—Yes.

11,524. How far is the end which you are driving from any winze or shaft?—The end in question where we have that number of men is no more than four fathoms east and four fathoms west, about that.

11,525. What is the furthest point from any winze or shaft at which you are now driving a level or sinking a winze?—The furthest end from any winze is no more than ten fathoms I should think.

11,526. In your mine how far from any winze or shaft would it be safe to drive a level for the sake of the air?—Generally speaking, without a machine or without a winze, we ought not to drive more than about 15 or 16 fathoms.

11,527. Have you any close end in your mine?—No, we have no bad air at all.

11,528. How do you judge of whether the air is bad or not?—We can easily tell, because the candle will tell you, and besides that a miner would feel it, if it was bad air at any time.

11,529. Have you no other means of testing the air except by the candle, or by the feelings of the men?—No.

11,530. In your mine have you any place where the candle is obliged to be put on one side to burn?—No place at all I believe in the mine.

11,531. What is the longest time that the smoke takes in clearing away from any one level or winze when you are sinking a winze?—Sometimes in some parts of our mine the smoke will remain to a certain extent for two hours, but it is smoke which does not injure—it is smoke which is cool because there is pretty good air; the smoke does not entirely go away, but it is cooled, it is not very thick.

11,532. In which level would that be the case now?—Our mine is in the moor principally; it is low, and the part in which the smoke stays the longest is called Hill's part of the mine—that is the deepest part of our mine; it is the 90 fathom part; but it will be all through the mine just a little mist for two hours. After blast in the morning it may remain for two hours before it entirely goes away.

11,533. (*Mr. Kendall.*) The surface of your shafts are all in a hollow?—Not all of them, but they are so at Hill's part of the mine; they are low in the valley.

11,534. (*Chairman.*) Out of which shaft does the smoke ultimately find its way?—You may see the smoke come out of two or three shafts, not any one in particular.

11,535. Does it always come up the same shaft or does it vary?—It varies.

11,536. According to the wind?—According to the wind; you will find a draught in the levels, sometimes it goes east and sometimes west, that is very often the case.

11,537. Does it generally change with the wind?—Yes.

11,538. If it is a muggy day, without much wind, I suppose it does not go up much?—Yes, it stays longer then than when there is a brisk air.

11,539. How long have you had charge of Wendron Consols mine?—About four years.

11,540. Have you had any accident?—We have never had a fatal accident since I have been there.

11,541. Have you had any other accident?—Nothing at all serious.

11,542. Have you had any accident by blasting?—Nothing at all by blasting; there was one man who was our pitman some three years ago who caught cold, and it was supposed that he died from the cold which he caught; but we have had no serious accident; we have had no death at all by accident since I have been there.

11,543. Is a separate account kept of the club money?—Yes.

11,544. Is it presented to the adventurers?—That is charged as the sick men may require it.

11,545. Is the club money for visible hurt?—Yes.

11,546. How much is charged to the men for it?—6*d.*

11,547. Is it only for visible hurt?—Only for visible hurt, except we are satisfied that a man has received an injury and cannot work; if we cannot see a wound; yet if we know that he has received an injury we allow him the money; for instance, if there is a sprain in the arm or the leg there may be no visible wound, but we allow him the money.

11,548. Have you any pensioners now receiving relief?—We have one.

11,549. Do you consider the club money as belonging to the adventurers or to the men?—We consider it as belonging to the adventurers.

11,550. What are the men charged for candles?—They are charged 9*d.* a pound.

11,551. And how much for powder?—8*d.* a pound.

11,552. Is there any charge for the barber?—The barber is charged and he receives his money monthly.

11,553. How much is charged for the barber?—I believe it is 2*d.*

11,554. Do the surface men pay the barber as well as the underground men?—Yes.

11,555. At what age do they begin to pay for the barber?—Those who receive 30*s.* a month; after that I think we charge the barber to them.

11,556. And if they work underground is it the same thing, or do all pay underground?—All those underground who receive men's wages pay for the barber, but no boys; those who are alike in partnership pay for the barber.

11,557. In your time you have never had an accident by explosion?—Not one.

11,558. Do you use any particular precautions?—We never allow our men to put any iron upon the powder or upon the cartridge; we compel them to settle the powder in with a wooden stick. Formerly they used to put in an iron bar, and in some places they had brass at the end of the bar to settle the powder, but neither of them is safe nor at all essential I think. We have put up papers in our mine not very long ago, stating that if they were known to use iron or anything but wood they should not receive any club money if an injury or accident occurred.

11,559. But they must use an iron for driving the tamping down?—Yes; it is of course safer then. After the powder has settled and the wadding is put upon the powder it is safe to use iron, it is essential. That is the precaution which we take.

11,560. Do you use cartridges otherwise than in wet places?—No; we always use the naked powder where the hole is not wet.

11,561. Supposing they neglected to swab away the powder at the edge of the hole, would not that be dangerous?—Yes. After the powder is put in the hole it should always be wetted with the swab stick.

11,562. If that were neglected might it create an accident?—Yes; and I believe that many accidents have occurred owing to the neglect of it.

11,563. Did you ever know or hear of any accident from driving the tamping down hard with an iron rod?—I think that there can be no danger of that. You may drive your tamping as hard as necessary and as hard as you please after the first laying of tamping has settled. The first thing that should be put in upon naked powder should be a little something very soft, and if the tamping is at all sparry it is very dangerous to settle that much.

11,564. Would it be dangerous to use an iron rod with sparry tamping?—Yes.

11,565. How would the powder ignite; would it be by the contact of the steel in the tamping with the rod

ST. AGNES.

Capt. J. Taylor.

9 August 1862.

or the country?—If the tamping is sparry it might cause ignition by rubbing against the side of the hole, or if you used iron it might strike fire. I think that if you even settled tamping with a wooden stick it might ignite by striking against the side of the hole.

11,566. (*Mr. Holland.*) But that by putting soft stuff it is safe?—You should never put a rough spar upon naked powder, no matter what you settle it with.

11,567. (*Chairman.*) What do you supply the men with as tamping?—In Wendron Consols we use mostly cartridges or tubes. Sometimes one and sometimes the other.

11,568. Do you mean paper tubes made by the men?—No; they are a sort of vellum cloth made water-proof. They are sent to us empty and the miners fill them; they put such a quantity of powder as may be required. Waddings with those are always sent. The wadding is generally made of cotton waste.

11,569. Supposing that the hole is small and that the cartridge is too large for the hole, do you think that by pressing down that cartridge into the hole you could ignite it?—Some have thought so, but I can hardly conceive how that is possible if you are settling your cartridge with wood. I do not think that that is likely to be the case.

11,570. For safety you would recommend cartridges and waste for tamping?—I have no objection at all if you have dry ground to the naked powder.

11,571. Do you not think that there is always a chance that the men may leave some along the edge?—They must never do that.

11,572. But is there not the risk of it?—There is no need of it. The men must use a swab stick and wipe the hole.

11,573. Are the men charged with the expense of the cartridge?—The mine has to provide them. The men are certainly charged, but then the mine must supply the men with them in the first place, and the men must get their living whatever materials they use.

11,574. Might the cost of them be an objection to their being generally used?—Any mine agent ought not to object to the use of anything beneficial to the miner or the mine, but in dry ground there is no need for using tubes or cartridges.

11,575. But you think that with tubes or cartridges in dry ground the chances of an accident are less?—I am sure that I could with safety charge 1,000 holes without any accident, without any tube or cartridge.

11,576. Would it be as safe for an inexperienced or young hand to charge a hole without a cartridge or tube as with a cartridge or tube?—I do not think that it would. With a greenhorn or a person who was just going to begin to do anything of the sort, of course it might be safer with a tube.

11,577. How many boilers have you in the mine?—Five boilers and three machines.

11,578. How often have you the boilers cleaned out?—Our boilers are cleaned out on an average about every two months.

11,579. Is the water good?—The water is very good.

11,580. So that there is not much accumulation in the boiler?—There is very little accumulation.

11,581. How do you test the quantity of water in the boiler?—By the cocks.

11,582. Have you any glass tube?—No.

11,583. Have you more than one safety valve to your boilers?—We have two.

11,584. Are they both in charge of the engine man?—Yes; we take care to have good careful engine men, and we have never had any accident.

11,585. You have heard of accidents?—Yes, of course.

11,586. Do they constantly occur?—They very often occur.

11,587. In your opinion what do those accidents arise from?—Very often from the want of feed being kept in the boiler.

11,588. (*Mr. Kendall.*) You have worked in a great many mines, have you yourself known of any accident?—I have worked in several mines during my time.

11,589. (*Chairman.*) Have you ever known of any accident?—We have all heard of accidents.

11,590. Can you name any mine at which you have heard of any boiler accident occurring?—Yes, I can name them of course—several; I can name one that took place not more than six months ago, I suppose, in our neighbourhood; it was an accident by a boiler explosion at the Wheal Lovel Mine; no one was killed; that was about six or seven months ago.

11,591. Do you know how that accident happened?—I cannot tell you how that happened, it is impossible to tell you that.

11,592. Have you worked up to your present position from that of a miner?—Yes.

11,593. You have worked in many mines; in any mine in which you have worked has there been a boiler explosion whilst you were there?—I think not, in neither one that I have worked in.

11,594. (*Mr. Holland.*) You were speaking about soft wads over the powder; is that, in your opinion, a very important precaution?—Yes, I think that that is very essential; unless you have a very good sort of tamping it is very essential to have a wadding if you have a tamping that is fiery or sparry.

11,595. What thickness of soft wadding is necessary?—About one inch.

11,596. Then, if I understand you, you put the ordinary tamping on that, and can safely ram that as tight as you like?—Yes.

11,597. If you have swabbed the hole well out you feel quite safe?—Quite safe.

11,598. Even although you tamped with an iron bar?—Yes.

11,599. Would it not be safer to use a copper or a bronze bar lest there should be any grain of powder left that might be ignited?—If you take care always to clear away the powder there is no danger.

11,600. As men are careless would it not be as well to have a second precaution, and to use a bronze bar lest an accident should occur?—It would do as well, there is not so much fire in a bronze bar as in an iron one. I have seen copper bars, as they term them, that would strike fire.

11,601. So as to ignite powder?—Yes.

11,602. Are you quite sure of that?—Yes. I do not know whether they use them now, but years ago they used to use them always in the parish of St. Just. I have not seen them in Illogan and Camborne.

11,603. You believe that a copper bar would strike fire so as to ignite powder?—I am quite sure of it.

11,604. The precaution that you rely upon is a soft wad put over the powder, and a good swabbing of the hole?—Yes.

11,605. Those are essential precautions?—Yes when you use naked powder.

11,606. (*Mr. Davey.*) You say that you have seen a copper rod strike fire; was the spark it produced a bright one, or of a pale blue colour?—It was the same fire as the borer would strike. I have tried it scores of times when we have had a new copper bar, as it is called.

11,607. Was the bar you speak of made of copper?—There was copper in it—that is, what the miners term copper—such as they used to have. I have seen a bar rubbed against the wall, and have seen fire come from it.

11,608. (*Mr. Kendall.*) There must have been a good deal of alloy in it?—Yes, no doubt.

The witness withdrew.

Mr. JOHN BRYANT WILKIN examined.

11,609. (*Chairman.*) Of what mine have you charge?—Wheal Basset and Grylls.

11,610. Have you charge of any other mine?—No.

11,611. About how many men are there employed at the mine?—We have 180 altogether.

11,612. What is the deepest level at which you are working?—We are now working at about 40 fathoms; that is the deepest level.

11,613. Have you ever seen men working in what is called poor air?—Yes, I have myself worked in it; and I have seen men working in it of course many times.

11,614. By what other means than that of the candle not burning well, can you ascertain whether the air is poor?—We feel it in the chest—a want of something—a faintness; we cannot work, and cannot make that effort that we could in good air; a person finds out that there is not anything to breathe.

11,615. Do the miners recover immediately on going into the fresh air?—I think not; not immediately, but of course if they got into better air, and exerted themselves, they would find that they had something to work upon.

11,616. Have you known men who have been working in poor air go to another level, and there work without feeling any effects from having worked in poor air before?—In a mine where I had the management, and where there was the worst air, the men, before going into good air, required medical treatment in order to prepare them; they were not fit to work in good air for a week or two; they were worse when they went to work in good air than while they continued in the bad air. For the first week or two, after going into the good air to work, they felt such a change that they required to have an emetic, and some other treatment.

11,617. Was it owing to any difference in the temperature?—It was not the temperature, it was the want of the air that they had been employed in, and then getting into good air to work; it had an effect upon their system, so that they did not feel well, and they were sickly about it.

11,618. But after working for a certain time in the good air, and being under medical treatment, they recovered themselves?—Yes.

11,619. Have you ever known any miners who suffered permanently from the effects of the bad air?—Yes, I have seen many laid aside by the bad air.

11,620. In what mines especially had those men worked?—There was one of those men that I speak of from Trumpet Consols.

11,621. Was he not able to work in the mine?—He wore out soon, and he is dead. The miners droop away when they get worn out, and catch cold, and die.

11,622. If a man was to leave off working underground, and was to come to work at grass, do you think he would then recover?—He would last many years longer.

11,623. If he were to go back to work in the mine after he had been affected in the way you have described, what would be the result?—If he kept at it until he was done up he would very soon succumb to it, but by giving in and going to some other employment he would save himself; if he were to drive a donkey cart and carry coals about. I saw one just now who had been an old miner, and I have known him for many years.

11,624. Did you ever suffer permanently from any ailment?—Not myself.

11,625. In the mine with which you are connected, are there any ends where the air is close?—Not that are really bad; they are close, as will naturally be the case.

11,626. How far is it safe to drive from any shaft or winze to put in a rise?—If a level is driven say 7 or 7½ feet high, and 4 feet wide we can get in 30 or 40 fathoms; more than that would be very close.

11,627. If you are following a lode, would it make any difference whether you had to sink downwards or incline upwards?—If we are following the lode, we can continue to a long distance sometimes, but, unless there is additional height, it would not be safe to go any further. I think that a great deal depends upon the size of the passage.

11,628. When the air gets very close, what machines do you put in?—I generally use a waterfall if I can get it.

11,629. Is that the best contrivance, do you think?—Yes; I think so. We are turning down the water at our mine at two different shafts to blow the air into the ends from the surface. The water cools it as well, and it is about as cheap a method as any; we let the water fall down a pipe in the shaft, and the bottom end of the pipe goes into a cistern, and then there is another pipe from that which is obliquely taken into the end.

11,630. How do you couple on the pipes?—We stick on a false pipe on the side of the other, and take the air out of the false one.

11,631. I suppose the end of the pipe is made to take on and off on account of the blasting?—No; we bring it in within a few fathoms; it answers the purpose. Not close up.

11,632. After you have put in a pipe, in how much shorter time is the powder smoke cleared out of a level?—I think it would get out in about half the time; if a pipe is well in, it will get out in a quarter of an hour; the closer the pipe is in the better.

11,633. You cannot take it quite close in, on account of the blasting?—No.

11,634. Have you ever tested the quantity of water or the quantity of air that you have sent down in that way?—No; we measure it by putting a candle against the pipe, and if it blows it out, or nearly so, we consider that a good test.

11,635. (*Mr. Holland.*) How much water does it consume?—It is just a small stream; two gallons a minute I should think would give a good circulation of air.

11,636. (*Chairman.*) How many boilers have you at work?—There are five working.

11,637. Is the water that is used good?—Very good at our mine.

11,638. How often do you clean out the boilers?—Once a year.

11,639. Do you consider that that is sufficiently often?—Quite often enough.

11,640. Have there been any accidents with the boilers?—Never.

11,641. (*Mr. Holland.*) What is the size of the pipe that blows the air into the mine?—We use different sizes; for the fall about eight inches within.

11,642. What is the size of the horizontal pipe?—About five inches within; there are two pipes, one going east and the other west from the perpendicular one.

The witness withdrew.

Mr. JOHN HENRY LAMBRICK examined.

11,643. (*Mr. Holland.*) You have, I believe, been in practice here as a surgeon for a long time?—About 12 years.

11,644. Have you seen a good deal of the miners' complaint,—that complaint from which they generally suffer?—Very frequently, and continually those cases fall into my hands.

11,645. Are you of opinion that there is a marked distinction between what is called miners' complaint and phthisis?—I think so.

St. Agnes.

Mr. J. H. Lambrick.

9 August 1862.

11,646. Have you any doubt about it ?—No ; it is a bronchial affection principally, and we call it miners' consumption. I think that it is decidedly a bronchial affection.

11,647. Have you often seen pneumonia mixed with it ?—Very often in its earlier stages.

11,648. What do you think is the first morbid condition ; bronchial ?—Yes, and then the substance of the lung is afterwards attacked.

11,649. Do you often find contraction of the bronchial tube some time before anything else takes place ?—Most decidedly, from repeated attacks of inflammation or irritation of the tube, from repeated attacks I think that the lining of the bronchial tube gets thickened, and the tube gets narrowed in its diameter.

11,650. Do you think that hectic fever is of rare occurrence in this complaint ?—In my experience it is.

11,651. Is spitting of blood of rare occurrence ?—Yes, decidedly.

11,652. Is sympathetic diarrhœa an unusual symptom ?—Yes.

11,653. There is less constitutional disturbance, is there not, than in phthisis ?—Yes, very much less ; indeed, we have just the same character of complaints here as elsewhere ; upon the whole I think that our miners are healthier than in many districts of Cornwall.

11,654. Do you attribute much of the bronchial irritation that the miners suffer to the dust ?—Yes, and to their exposure to cold when heated.

11,655. Do you also attribute it to alternations of temperature ?—Yes.

11,656. And to the powder smoke ?—Yes ; that is one element decidedly.

11,657. Do you consider alternations of temperature a very prominent cause ?—Most decidedly.

11,658. Do you think that the injurious effects produced by these various causes would be considerably diminished if the miners were to bathe when they ascend from a mine ?—Yes, unquestionably ; they would not then feel the difference in the temperature so much in a tepid bath.

11,659. Do you think that that could be managed with very little expense and trouble ?—Yes.

11,660. Do you think that the miners would cheerfully do it ?—Yes, I think so, if the advantages to themselves were pointed out. I think it would be a very reasonable thing; and I think it might with very little expense be put into practice.

The witness withdrew.

Adjourned to Tavistock on Tuesday next at half-past 10 o'clock.

TAVISTOCK.

Tuesday, 12th August 1862.

PRESENT :

The Right Honourable Lord Kinnaird, K.T.	John St. Aubyn, Esq., M.P.
Richard Davey, Esq., M.P.	P. H. Holland, Esq.
Nicholas Kendall, Esq., M.P.	

The Right Honourable Lord KINNAIRD, K.T., in the Chair.

Captain James Phillips examined.

Tavistock.

Capt. J. Phillips.

12 Aug. 1862.

11,661. (*Chairman.*) Of what mine have you charge ?—The Bedford United mine, near Tavistock; it is about three miles from here.

11,662. Have you charge of any other mine ?—No.

11,663. Is the Bedford United mine a tin or a copper mine ?—It is copper.

11,664. Does it produce copper only ?—Yes.

11,665. What is the nature of the country ?—It is killas.

11,666. Is it entirely killas ?—Yes.

11,667. How many men are there employed underground in your mine ?—About 121.

11,668. How many persons are employed above ground ?—Upon the dressing-floors there are about 60, and then we have four trammers, two kibble fillers, and two landers, engine-men, and four smiths.

11,669. What is the total number ?—I will supply that.

11,670. What is the youngest age at which you allow boys to go to work underground ? — The youngest is about 17 ; I should say from 16 to 17.

11,671. You do not allow boys of 10 years of age to go underground ?—Not so young as that. I do not know whether we have any from 15 to 16.

11,672. What is the deepest level at which you are now working ?—From the surface the deepest level is 148 fathoms.

11,673. How do the men ascend and descend the mine ?—By what we call footway ladders; 130 fathoms is the deepest level we are working at.

11,674. How many pairs of men are there employed in that level ?—At the 130 there are 16, that is the whole that are employed at the 130.

11,675. How many other levels are you working at ?—There is the 130, then the 115, and the 103 and the 90, those are our principal levels now ; the greatest number work at the 115, and above the 115.

11,676. What description of work are you doing in the 115, are you sinking a winze or driving on the level ?—We are driving, we are not sinking anywhere in the mine.

11,677. How far is it from any shaft or winze where you are driving ?—I suppose our length from where it is ventilated is somewhere about 40 fathoms, that is in the 115 ; the end in the 115 is about 40 fathoms from the nearest winze or shaft.

11,678. In what condition is the air at the end of the 115 fathom level ; do the candles burn freely ?—They burn very well. We have put in, until we have ventilated another winze, air-pipes to draw out the foul air from there, so that the end is ventilated very well.

11,679. Do the candles burn without being tilted on one side ?—Yes.

11,680. What machine is it that you use to draw out the foul air ?—It is a duck machine, and it is worked by the same rods as the water wheel, and it draws out the foul air instead of forcing air in.

11,681. You produce circulation by drawing out the air ?—Yes.

11,682. Is that machine applied to any other level ?—No, it is not in the mine.

11,683. In the 130 fathom level how far are you driving from any winze ?—I suppose we are about 20 fathoms from the shaft.

11,684. Is the air so good there that you have no

need to use any artificial means ?—We do not want anything there, the air is very good there.

11,685. Does the duck-engine answer for drawing out the bad air ?—Yes.

11,686. Do you approve of the plan of extracting the foul air in preference to forcing in fresh air ?—Yes; I have proved it in our mine a great many times, because in forcing in air you have a little fresh air along the end ; and if the foul air is so heavy that the fresh air has not strength enough to drive it out, by taking out the heavy smoke and the foul air, the fresh air goes in.

11,687. Where does the fresh air that takes the place of the foul air come from ?—We have ground stoped away about our shaft (the western shaft) in the mine, and there is a very great current of air from the surface down ; there is a down draught of fresh air from the surface.

11,688. And that is the air that takes the place of the foul air ?—Yes, it goes into the 115 fathom level as we take out the foul air.

11,689. According to your experience the powder smoke does not take so much time to clear away as if you forced in fresh air ?—No ; what we call the air pipes, when we shoot into these ends, drive out the powder smoke directly.

11,690. How long after the blasting is the smoke cleared away ?—I suppose in our 115 fathom level the men can go in and work comfortably in 10 minutes.

11,691. How long is it before the smoke is completely cleared away ?—It does not stay long, not when we have got the pipes all in good order.

11,692. How long do you think the smoke would remain without the use of those pipes ?—Sometimes it would stay a good while ; I dare say you could not calculate upon going in to work again under half an hour, or three quarters of an hour, and in some places an hour.

11,693. In point of economy does it answer to extract the foul air and the powder smoke, so as to get the men in to their work again quickly ?—Yes ; but we do not only convey these pipes into the furthest ends, we calculate to ventilate by winzes if it is necessary to drive away ; and, when there are several men in a level, to put in these pipes, and instead of sitting down for an hour, they sit down for only a quarter of an hour, and they are able to do more work.

11,694. You say that you ventilate by a winze ?—Yes.

11,695. Do you adopt any means for the purpose of conducting air into any special level from a winze ?—No ; no means more than the levels themselves ; when we have put through this winze it naturally draws a current of air from one level to the other.

11,696. Of what height and width are the levels that you drive ?—We set our levels to be carried 6 feet 6 inches high, and 3 feet 6 inches wide.

11,697. In your opinion is that sufficient to ensure a circulation of the air ?—Yes, that is sufficient for the levels to put in a tram road and air pipes, &c.

11,698. What precautions do you take to prevent the men leaving the deads to accumulate in a level ?—We have a sufficient number of trammers and haulers to keep the stuff clear from the mine, so that no man is injured in the mines.

11,699. Do you do that, or is that part of the contract with the man who takes a pitch ?—We set what we call the trammers to clear out all the stuff in the mine, and they do that every day.

11,700. Are those trammers paid by the adventurers, or are they paid by the men who take a piece of work ?—They have so much a month to keep all the stuff clear in the mine.

11,701. Are the wages paid to the trammers deducted in the bal bill ?—The tut-work men allow 10*s.* a fathom for tramming that stuff, and the tributors give a guinea for 100 kibbles ; but that has nothing to do with the trammers, only we deduct this from the tut-work men's wages.

11,702. (*Mr. Holland.*) You pay them what you think a proper sum, and deduct it from the tut-work men's wages ?—We give the trammers so much a month.

11,703. You fix the price paid to the trammers ?—Yes.

11,704. (*Chairman.*) Do you think that that is a better plan than leaving it to the tut-work men and tributemen ?—Yes, because there would be always grumbling ; we find that it works better ; we keep the trammers and keep the hauling machines.

11,705. Have you ever ascertained what was the greatest heat at the end of any of these levels ?—No, I have not; but ours is not a very hot mine.

11,706. Have you ever experienced in the mine any poor air or cold damp ?—We had a little at one place before we had ventilated it, in a shallow level, but nothing else ; that was at our 36 east.

11,707. Was it cold damp or poor air that was found there ?—Cold damp, the candle would burn, but it was cold damp ; but there is not so much working there. I did not know that for some time, but we found that the men complained a little bit of it, and we had it ventilated directly.

11,708. What did the men complain of ; what was their sensation ?—They complained of weakness and so on in their limbs, and they did not know what was the matter; then I considered that there was cold damp there, and from that time we ventilated the place, and it has been all right since.

11,709. Was this in the back or in the winze ?—They were driving an end and a little working in the back ; it did not continue for more than a month.

11,710. How long do you suppose the men had worked in that place before they complained ?—Not for more than a month.

11,711. Were any of them thrown out of work in consequence of it ?—No.

11,712. Can you describe the difference between cold damp and poor air ?—I can hardly explain it, I suppose that there is not sufficient air to bring out the cold air that has been there for some time, but I can hardly explain it ; we do not take so much notice of these things when the candle burns all right.

11,713. When the candles burn all right then you think there is nothing to be afraid of in the air ?—Yes.

11,714. Have you any means of ascertaining whether there is cold damp in a mine except by your sensations ?—No, I do not know that we have had any such thing in our mine more than in this one place for a month.

11,715. In that cold damp the candles burned well ?—Yes.

11,716. In poor air they would not burn well ?—No, not in very poor air.

11,717. Has any accident occured in your mine in the last tour or five years ?—No.

11,718. No accident from blasting ?—No, not for these four or five years ; we had one small accident to a man who was putting out a hole in blasting, but he did not stay from work more than about a month.

11,719. Do you use any particular precautions to prevent accidents from blasting ?—Nothing more than that we generally caution the men to be very careful.

11,720. Do you use cartridges in your mine ?—We use what we call the safety fuze.

11,721. Do you use any cartridges ?—Only when there is wet ground.

11,722. Do you supply the men with material for tamping ?—No, they get that themselves.

11,723. Where do they get it from ?—They generally take it from the upper levels, and carry it down to the deeper ones ; the upper levels are what we call fair killas.

11,724. I suppose the swab sticks are made of oak ?—They are made of wood.

11,725. Do they fill in with them ?—No, they gene-

TAVISTOCK.
Capt. J. Phillips.
12 Aug. 1862.

rally use what we call the swab sticks, and swab out the hole, and then they run in the powder, and use the swab stick again on the powder, but our men are ordered to take some hard clay to put in first upon the powder, that is what we use in the mine, for, otherwise, they would use many different things in the mine, but that is a hard substance to go down with the swab stick.

11,726. Where is the clay that you have just mentioned obtained from ?—We pay about 7*s.* a ton for it; we get it down here; I do not know where, exactly, but the barges bring it up.

11,727. Is any charge for that made in the bal bill ?—No, the miners get the clay free.

11,728. Do they use an iron tamping rod ?—Yes.

11,729. Do you allow to each man a certain quantity of candles per week ?—Yes, we allow each man 2 lbs. of candles a week.

11,730. What price do you charge them for the candles ?—We charge them 8*d.* a pound.

11,731. In your mine do you use the small grain powder, or large grain powder ?—We use the large grain powder.

11,732. Do you find that that is more useful for blasting ?—I think it is in wet ground, we can do better with it.

11,733. What charge do you make to the miners for powder ?—We charge them 7*d.* a pound.

11,734. What other deductions are made from the miners; for club money ?—Yes, they pay 1*s.* 6*d.* a month.

11,735. Is that for the club and the doctor ?—Yes, we have no club, nothing but hurt pay. If they receive a hurt they have 1*s.* a day. Should a man receive a hurt in our mine, he is cared for until he can go to work again.

11,736. Do they pay 9*d.* for the club, and 9*d.* for the doctor ?—Yes.

11,737. How much is put down to be deducted for club money ?—1*s.* 6*d.* a man.

11,738. That is for the club and the doctor ?—Yes; that sum is deducted out of a man's balance, for club and doctor.

11,739. Is any account kept of the club money separate from the doctor ?—None.

11,740. How is the doctor paid ?—He receives so much a man from every man in the mine, each man pays so much to the doctor.

11,741. How much does he pay ?—I think the doctor's pay is 9*d.* a man; we have no club in the mine the same as they have in other mines.

11,742. (*Mr. Kendall.*) You charge the men in all cases so much a month, and you believe it is 1*s.* 6*d.* a month for the doctor and the club ?—Yes; the doctor has so much a month, and there is so much for hurt pay. In most mines there is a doctor and club account, but there is no club at all in our mine; that sum is deducted from the men, but it is put in the same as cost, there is no money in hand.

11,743. (*Chairman.*) You say the doctor is paid so much per head from every man ?—Yes.

11,744. Not so much per month ?—No, he has so much a man.

11,745. Do you know what he receives per head from each man ?—I think it is 9*d.*, we have no money in hand in the mine the same as some have.

11,746. In paying the men what proportion of notes, and what proportion of silver and gold do you obtain from the bank on pay days ?—The paymaster, the manager, and purser of the mine, always brings cash, generally gold and silver and pence, hardly ever any notes, because it is more convenient for the men to change.

11,747. How many boilers have you at work ?—One, and that is for the steam engine.

11,748. How often is it necessary to clean out the boiler ?—About once in six months.

11,749. Have you had to stop the pumping while that has been done ?—There is no pumping, ours is waterwork, this is only a drawing machine; we pump by means of water power.

11,750. Have any of your men been out of work from illness or accident during the last three years ?—No.

11,751. Is one month's pay of the men always kept in hand ?—Yes.

11,752. What proportion of tribute men do you employ as compared with the tut-work men ?—There are about 70 employed on tutwork and about 50 on tribute work.

11,753. Do you draw with a kibble or a skip ?—We have two drawing shafts, and from the inclined plane we draw with a skip; at the other shaft we draw with the kibble.

11,754. Do the men ever come up in the skip ?—No.

11,755. Do you consider that it is cheaper to draw with the skip or the kibble ?—When you have the convenience I think that the skip is the cheapest; it gets up the most stuff in the same number of hours.

11,756. Is there any reason why it should not be applied in cases where kibbles are now used ?—No, I do not think there is.

11,757. (*Mr. Holland.*) Would the 115 fathom level be hot if there was no blowing engine used ?—No, not very hot; but our mine is not very hot at all, it is not the depth to be very hot.

11,758. How large is the duck engine that you employ ?—It is two feet square.

11,759. What length of stroke is it ?—Seven feet.

11,760. How many strokes a minute ?—Our wheel is going about four strokes a minute.

11,761. It has only one action, I suppose, and only draws when it lifts ?—No.

11,762. What number of men are working at the end which it ventilates ?—There are two pairs, 12 men. There are two working together at the end. They are not working more than four men together. There are 12 men, but they do not work more than four together. They work four in the forenoon, four in the afternoon, and four in the night. There are 12 on, but only four work together. I think that this drawing machine is about two feet square.

11,763. Do you find that the duck engine is enough to keep the miners well supplied with air?—Yes, there was very good air before it was put in; it was put in to draw out the powder smoke and so on.

11,764. (*Mr. St. Aubyn.*) What is the general condition of the men in your mine with regard to their health ?—Their health is very good.

11,765. How long has the mine been working ?—I have been there going on 21 years.

11,766. Are there many cases of what is called miners' complaint in that mine ?—No, we have not had any cases.

11,767. Is the mine well ventilated throughout ?—Yes, it is very well ventilated throughout, indeed it cannot be better.

11,768. How do the men come up to the surface, by footways ?—Yes, there is a very good footway for the mine.

11,769. What is the distance between the staves, 10 or 12 inches ?—12 inches; some are 10, but most of them are 12.

11,770. Have you ever known an instance of miners' complaint in that mine ?—No.

11,771. (*Mr. Kendall.*) You say you have been employed in this mine as agent for 21 years ?—Yes, I have been there for 21 years.

11,772. Did you before you became agent work as a common miner ?—I worked as a common miner before that.

11,773. How many years did you work as a common miner ?—I am now 60 years of age, and I have been working since I was 12 years of age.

11,774. You have been in the habit of going underground both as miner and as agent from that time to this ?—Yes.

11,775. Do you enjoy good health?—I believe very good.

11,776. Do you feel yourself very well ?—Yes. I

have been working underground all that time, and I have been underground every day.

11,777. Have you ever been in the doctor's hands?—No, not for anything particular, to say anything about.

11,778. Do you go underground now?—Yes, sometimes every day in the week, always three and four times in a week; the last week in a taking I go underground every day; but, I suppose, on an average four days a week.

11,779. You go underground on an average four days a week throughout the year?—Yes.

11,780. (*Mr. Holland.*) Have you ever worked in poor air?—Yes, when I was young a little; but I used to get out of it as well as I could. I did not like it very well.

11,781. (*Mr. St. Aubyn.*) Is your mine more healthy than other mines in the neighbourhood?—I do not know. There are many well ventilated mines, but some little ones are very badly ventilated that I have been in inspecting sometimes. We have three shafts from the surface, and a deep adit.

11,782. Is your mine in a better condition, generally speaking, than the mines in the neighbourhood?—I do not know. All I can say is that ours is very well.

11,783. (*Mr. Davey.*) What sized pipes do you work in the duck-engine at the 115 fathom level?—Four-inch pipes, I think.

11,784. Do you find that they are sufficiently large to draw the air from a distance of 40 fathoms?—Yes.

11,785. How close are they in to the end?—They are not within, I suppose, 10 or 15 fathoms of the end.

11,786. Do you find that you can withdraw the foul air that distance from the end?—Yes; you cannot get them right into the end. The men are working in the back, and if you do get them right into the end, they all knock them up.

11,787. In the shallow level to which you have referred, where there was cold damp, did you not discover it when you were inspecting the end?—No, I did not take any notice of it; it was not for long; the men complained a little bit of what we call cold damp.

11,788. But you did not discover it yourself?—Not at all, because I was not in the end long enough every day. I always go into these places every day, but I do not stop above ten minutes or a quarter of an hour, and then I go to other parts of the mine. I did not find it out myself.

The witness withdrew.

Captain Zacharias Williams examined.

11,789. (*Chairman.*) With what mine are you connected?—Huel Friendship.

11,790. Are you the principal agent there?—Yes.

11,791. What other mines have you charge of?—There is a little mine about two miles off; but there are but a few hands there working.

11,792. What is the mine called?—Devon Wheal Union; there are about ten or a dozen men there working.

11,793. What kind of ore does Wheal Friendship produce?—Yellow copper ore.

11,794. Is there any mundic in it?—Yes, and a small portion of lead, and occasionally some tin, but very little worth notice.

11,795. Is there a good quantity of mundic in the mine?—Yes, a great deal of mundic.

11,796. Is it in sufficient quantities to sell?—Yes; we have sold several hundred tons.

11,797. About how many men are employed underground?—On tut-work there are 54 men and 24 boys, making altogether 78. On tribute there are 30 men and 34 boys, making together 64.

11,798. Are these all employed underground?—Yes.

11,799. Do you know what number of people are employed above ground?—Fillers, landers, &c., 11; the total of all being 153.

11,800. Do you limit the age at which boys are permitted to go to work underground?—We generally calculate to take them in at from 13 to 14 years of age. If there should be at a particular time a certain one who is younger, the father always takes charge of him. We give him over to the charge of his father, and he must take all the consequences of anything that may happen.

11,801. You allow a father to take his son down into the mine at any age he pleases?—Yes, from 12 to 13.

11,802. But would you prevent a father taking his son down if the boy was younger than that?—We should object to it.

11,803. What is the deepest level in your mine at which you are working?—The 240-fathom level.

11,804. How do the miners ascend and descend?—By ladders.

11,805. What is the distance between the staves of the ladders?—12 inches.

11,806. At how many levels are you now working?—There is only one pair now working under the 190, in the western part of the mine; in the middle part of the mine there is another pair working under the 100, that has not yet communicated so far west as the deeper part.

11,807. The principal number of your men are working in the shallower levels?—The principal part of our men are working above the 100-fathom level; there are only six men working down at the 210, so deep as that, and they are about 10 fathoms under from any communication, no more than that; they have plenty of good air.

11,808. How far are they from a shaft or a winze?—They are from a winze about nine or ten feet; they have but just made a beginning to start off from a certain winze in the way of sinking. We are now driving a level to get over a piece of ground to communicate at the 220 further west.

11,809. The larger number of your men are working at the 90?—Yes.

11,810. How many pairs are working in one level?—There are 6 sinking a shaft; 18 men and boys at and above the 100 fathom level.

11,811. That is, the whole of a core?—Yes.

11,812. Are you at present driving any level, or sinking a winze, or putting in a rise beyond 10 fathoms from any communication?—Yes.

11,813. How far is it from any winze?—We are, I suppose, about 20 fathoms at the 100 fathom level to the east of any communication.

11,814. Where you are driving 20 fathoms from any communication, have you a good draught there?—There is as good a draught as there is here.

11,815. Where does it come from?—It comes through the level from one shaft to another; then we have, to make everything convenient, to put a trap door into this level, and we have pipes to carry a rush of air into this end, so that it is as comfortable to work in as it would be here as to the air.

11,816. How long is it before the powder smoke is cleared away?—Perhaps ten minutes or a quarter of an hour.

11,817. How long is it getting away altogether from that level?—It is but a trifle of time; there is as fine a draught as you would wish.

11,818. You introduce fresh air by means of pipes?—Yes, into this end.

11,819. Of what size are those pipes?—Four inches in diameter.

11,820. (*Mr. Kendall.*) How long has this mine been working?—I cannot say; I can tell you how long it has been under Messrs. Taylors, I believe

is rather above 60 years; it is one of the oldest mines in Devonshire.

11,821. (*Chairman.*) Are there very extensive workings in the mine?—Yes.

11,822. Is there a communication between all the old workings and the present workings?—No, not all; there is a leading level at the 100-fathom level, and that is connected with the general run, but it is not down so deep under the 100-fathom level; there is not any communication; as we go on west the mine goes down, it does not keep all down at the regular level of working.

11,823. Does the timber decay at all in your mine?—Yes, there is a decay of timber in places, but we do carefully attend to that, in securing it.

11,824. In the old part of the mine which communicates with the present workings, is the timber decayed at all?—No; the greatest decay of timber that we have is in the western part of the mine.

11,825. (*Mr. Kendall.*) What do you imagine the decay of the wood is owing to?—I cannot tell.

11,826. (*Chairman.*) Is there good ventilation in the part of the mine you have referred to?—It cannot be better.

11,827. I mean where the wood decays?—Yes.

11,828. Does the shaft in that part of the mine where the wood decays act as an upcast shaft?—No, it goes down; we have two inclined planes in the mine.

11,829. The draught is sometimes upcast and sometimes downcast?—Yes, it changes with the winds oftentimes.

11,830. When there is no wind and it is a very hot day above, I suppose there is not much draught either way?—Yes, there is plenty of draught then travelling from one shaft to the other.

11,831. But there is none from the surface, is there?—Yes, it must go down to come up.

11,832. Does the decay of the timber take place where a level or a shaft is damp?—Yes, more particularly; but it sometimes decays where it is dry.

11,833. (*Mr. Holland.*) Does it decay most where it is dry?—I do not think it does; it decays where it is as dry as it is here.

11,834. It will decay also where it is damp?—Yes; where it is damp it goes all to a mummy, so that you can squeeze it up in your hand.

11,835. (*Chairman.*) In the course of your experience have you ever found poor air or cold damp in your mine?—Yes, we have had poor air, and we have had what we call cold damp for a certain time, where we have had reason to have a long distance; sometimes driving for a communication, and some times we are driving crosscuts to make a trial, and it is not possible to get a communication unless you meet with something occasioned by sinking the shaft.

11,836. How far have you ever driven from a winze or a shaft in either exploring or making a communication?—I should think 150 fathoms; but you must please to understand that we never have done that without the convenience of forcing in air.

11,837. When you have driven 150 fathoms from a winze or a shaft you have forced air in?—Yes, we never calculate to go more than about 20 or 30 fathoms before we begin to do that.

11,838. Do you think that forcing in air is a better plan than extracting the foul air?—Yes, I do.

11,839. Does the powder smoke clear away quickly?—Yes.

11,840. Have you ever tried to exhaust the air as well as forcing it in?—No; we never made a trial of that.

11,841. When you have found the air beginning to get close, have you employed any means for forcing in air?—Yes.

11,842. How do you tell when an end is close?—It will tell for itself; there is a heaviness or a deadness to what there is where the air is lively and active.

11,843. Have you any means of ascertaining whether the air is close, except by the men complaining that they feel it, and are affected by it?—Yes, in a very close place a candle would not burn so freely.

11,844. When you find that you are obliged to incline the candle, do you immediately resort to some means of forcing in air?—We do it before; we do not allow it to come to that. We always keep in the mine conveniences for throwing air in before there is anything to complain of.

11,845. Have you ever known the men suffer from working in poor air?—I have heard of many; not in this mine.

11,846. Have any of the men under your charge suffered from it?—No; we have never had any occasion to see anything of the kind; we always make preparation as I tell you.

11,847. Have you ever seen men suffering from the consequences of working in bad air?—Yes, I have in Cornwall.

11,848. But not in Devonshire?—Never one in Devonshire.

11,849. (*Mr. Kendall.*) In what part of Cornwall have you seen men suffering from working in poor air?—About Gwennap, say 30 years ago.

11,850. (*Chairman.*) Have you worked as a miner in Cornwall?—Yes.

11,851. Have you ever worked in poor air?—I have worked in close places, but I never felt anything—never anything to feel any effects from it, but I have seen men afterwards who have been working in it.

11,852. What quantity of candles do you allow to your men per week?—About 1½ to 2 lbs. a week per man.

11,853. Are they patent candles?—No, the common candles.

11,854. What charge do you make to the men for the candles?—7*d.* a pound; some do charge 8*d.*

11,855. Do you use the fine or the large-grained powder?—We use some of both, but generally the large grain.

11,856. Which of the two do you prefer?—We like the middle sized generally the best.

11,857. What charge do you make for the powder?—The men do pay 50*s.* a hundredweight for the powder; that is 7*d.* a pound.

11,858. Do the miners contribute any club money?—Yes.

11,859. Is that to provide for visible hurts or for sickness?—Our club men pay 1*s.* 6*d.* a month; that is 7*d.* for the doctor and 9*d.* for the sick.

11,860. Does "sick" mean for visible hurts?—Yes, it is, should they be sick and hurt; but in addition to the fund they get 1*l.* sterling per month. If they are hurt they get 20*s.* a month; if sick they receive only 15*s.*; if they are hurt as well then they have 35*s.* a month. It is added together, the sick and the hurt pay.

11,861. Is there a separate account kept of the club money and of the doctor's money?—Yes.

11,862. As between the club and the doctor?—Yes.

11,863. There is a distinct and separate account kept of the club money?—Yes.

11,864. Is that account of the club money rendered to the adventurers?—No; that is always kept as the separate account of the men; that is all they can claim in a certain sense, but we have been for years, so that we have paid 3*l.*, and 4*l.*, or 5*l.* a month more than the sick money would provide. We have had so many men worn out—men lying on the club—that it would take more money than the monthly contributions of the men would provide.

11,865. How is that additional sum entered in your accounts?—It is stated in the accounts what it is for, as loss on the sick fund.

11,866. (*Mr. Kendall.*) Is it entered as a debt due from the club?—No; it is charged to the adventurers.

11,867. But still you keep a separate account?—Yes, of everything.

11,868. (*Chairman.*) How is that charge entered?—It is entered as sick pay.

11,869. Do you know from your own personal

knowledge how far the club fund has been insufficient to provide the allowances which you have been in the habit of making to the miners when sick, or when suffering from hurts?—No, not precisely so; but, perhaps, sometimes 3*l.*, sometimes 4*l.*, and sometimes 5*l.* a month it will run to; it depends upon the number of hands. There may be old men, and our men receive 15*s.* a month regularly. We have had many here in Tavistock for years. The amount is 4*l.* or 5*l.* a month. See last question, for many years, say 20 years the club contributions have not paid the claims.

11,870–2. Do you remember when there was a balance of club money in favour of the men?—No; for several years the club was going in debt, and I have heard that 500*l.* or 600*l.* was at one time charged to the mine, before the monthly deficits were charged as they occurred.

11,873. Is that now all exhausted?—Yes, and many scores of pounds more than that. See above.

11,874. (*Chairman.*) Has it become exhausted in consequence of the miners being off, or from old age, or from accidents?—Some of both; but we rarely have an accident, I am very glad to say.

11,875. Could you furnish the Commission with a copy of that account?—Yes, for seven or ten years, certainly, or twenty, if required.

11,876. What is the amount paid to the doctor?—Ninepence; but then he attends any man that is sick or hurt, and the family for that.

11,877. Is there any deduction made for the barber?—No, every man shaves himself.

11,878. What other deductions are there made?—There is nothing at all that I know of.

11,879. How many doctors are there connected with your mine?—We have three that attend at the mine; but every man is at liberty to choose his own doctor.

11,880. Out of the three?—Yes.

11,881. Are the doctors appointed by the adventurers?—No, they are not appointed by the adventurers, they are chosen by the men and accepted by the agents; the adventurers do not take any thought or care about those things; it is the mere wish of the men for such and such a doctor to attend them.

11,882. How do you ascertain what the wish of the men is?—We ask them.

11,883. How do you ascertain whether the men are or are not unanimous in the choice of a doctor?—When any man comes into a mine as a fresh miner to work we ask him then, or in the course of a month, what doctor does he wish to pay to, and he will say so-and-so, then this man is put down to pay to Mr. So-and so; that is how we do it.

11,884. But is it compulsory upon him to pay to one of the three?—No; there is no obligation, he may have any doctor, nor are they obliged to pay to a doctor if they have not a mind to do it.

11,885. Then they need not pay the ninepence if they do not choose to do so?—No.

11,886. Do many of the men object to pay to the doctor?—There are certain farming men who come in just as labourers, but not the miners.

11,887. Is that ninepence per head so contributed by the miners applied in payment of the doctors?—Yes; fairly I should think out of 150 men there are not 10 who are not under the care of the doctor.

11,888. Are the doctors satisfied with what they receive in that way?—We do not hear any complaint, and I believe that they are very well and fairly paid.

11,889. In paying your men what proportion of notes and of gold and silver do you obtain from the bank?—We never pay in notes; ours is generally in hard cash, gold and silver and pence; sometimes if there is a large pay required we may have a few five pound notes.

11,890. Does the bank object to give you all the money in cash?—No.

11,891. How many boilers have you at work in the mine?—We have one at the dry, but that is for the comfort of the men, just to enable them to warm their clothes; we have no steam in the mine. I should have stated that we have got 11 air shafts, and the deepest is at the 240-fathom level, the next is at the 220.

11,892. (*Mr. Holland.*) How many lodes are you working on?—Four or five.

11,893. Have you crosscuts to connect all those lodes together?—Yes, either at one place or the other.

11,894. Are the lodes worked deep?—Not all.

11,895. (*Mr. St. Aubyn.*) Is the health of the men employed in your mine good?—Yes.

11,896. Are there any cases amongst them of what is called miners' disease?—That is consumption; there is not one in the neighbourhood that I know of; not anybody who has worked in our mine.

11,897. Do you consider that your mine is in a good state of ventilation as compared with other mines in the neighbourhood?—I make no compaaison; it cannot be better, and I do not think there is hardly an equal to it to be found; many of the mines in the neighbourhood are very good.

11,898. Is your mine, upon the whole, better than most of them?—I do not think it is; but I do not think that I know enough about other mines to say; I think I can say this, that ours is as good as can ever be expected; there is not a poor air place that is being worked in the mine.

11,899. Do you bring all the men up by footways?—Yes, all of them.

11,900. Have you ever thought of having a man-engine put into the mine?—I should like it very much myself, but I am sorry to say that the mine is so poor that it will not afford it.

11,901. If you could have a man-engine in the mine you would rather prefer it?—I should be glad to have it.

11,902. You would of course require steam power for it?—No; it might be done with water.

11,903. How is the stuff drawn at your mine?—By water.

11,904. With a kibble?—On inclined planes; we have a coach (waggon).

11,905. Do you employ a skip?—Yes, it runs upon a railway.

11,906. How much underlie in a fathom is there before you begin to use a skip?—Perhaps we may go down 100 fathoms before we begin to use them.

11,907. You say that upon inclined planes you use a skip in preference to a kibble, how much underlie in a fathom is there in the shaft before you begin to use the skip?—Our inclines run from the surface down at a certain angle, about 45.

11,908. Do you consider that the kibble is better to bring up with in the right-down shafts?—No, I think that the skip is best with working guides, and a very good plan that is.

11,909. Have you ever brought any men up in the skip?—No.

11,910. Do you not approve of it?—No.

11,911. Have you ever seen it done?—No, neither do we let the men go upon our railroad anywhere to interfere with the rails.

11,912. Do you not consider it safe for the men to come up in the skip?—If the chain was to break the men might be killed.

11,913. But suppose you had a chain strong enough to avoid all reasonable chance of breaking, would you prefer it then?—It would be much easier; I do not know why it might not be done.

11,914. Are you aware that it has been done in Cornwall?—I have seen man-engines in Cornwall.

11,915. Have you never seen a skip?—I have seen them working but in drawing stuff; I have seen no men drawn up by it.

11,916. (*Mr. Kendall.*) You say that you wish there was a man-engine, but that you cannot afford it?—Yes, I should be very glad of it.

11,917. Do not you think that if you had put in a man-engine at the time when you could have afforded it the chances are that you would have been more successful in making discoveries and not so poor

Tavistock.

Capt. Z. Williams.

12 Aug. 1862.

as you are at present?—I do not know what difference that would have made in the poorness of the mine.

11,918. If you had had greater facilities for sending the men down to the bottom you would have got more men to go down who would have been able to work your ends cheaper?—I do not think so, I do not see that at all.

11,919. Would not the men have been able to do more work?—They would be there a longer time, and would be quicker down.

11,920. If they had been down a longer time, and if, therefore, they could have done more work, would not that have given them a better chance of making discoveries?—Possibly it might in the time, and it would be a saving to the adventurers, because the more work they do in the time the less price is required for doing it.

11,921–2. (*Mr. Davey.*) Although the not having a man-engine may save money to the adventurers, yet it would not prevent discoveries being made?—I hardly see that the advantage of it would be greater.

11,923. (*Mr. Kendall.*) You have stated that you have no poor air in the Devonshire mines, but that there was poor air in the Cornish mines; where did you find it there?—I have seen it in Cornwall, and sometimes in Devonshire, but very little; I have never seen many mines in Devonshire.

11,924. Where did you work in Cornwall?—I worked in Cornwall, first, in the parish of Crowan; there is an old mine there by the name of Crenver and Wheal Abraham.

11,925. How long ago is it since you worked there?—Somewhere about 40 years ago.

11,926. Was that the first mine that you worked at?—Yes.

11,927. Have you been employed as an agent for 40 years?—No, for about 30 years.

11,928. How long did you work as a miner before you became an agent?—About 20 years.

11,929. How old are you now?—I am in my 65th year.

11,930. How is your health now?—Very good.

11,931. Were you ever in the doctor's hands?—Yes, many times; sometimes with a pain in my head, sometimes with a pain in my side; but I have always escaped any accident.

11,932. Did the pain in your head and the pain in your side come on from working underground?—No, I do not know what caused it.

11,933. Do you go underground now at all?—Yes, four or five days a week.

11,934. Have you ever been down to the 240 fathom-level?—Yes, as often as in any other level whilst that level was being worked, but I have been down to the 230.

11,935. How did you feel when you came up again?—Very well.

The witness withdrew.

Mr. William Skewis examined.

Mr. W. Skewis.

11,936. (*Chairman.*) Of what mine have you charge?—Crelake.

11,937. Have you charge of any other mine?—Kit Hill I go to occasionally.

11,938. What number of men are there employed underground in Crelake?—There are about 86 at present.

11,939. How many of those are tributors and how many tut-workmen?—There are 24 men employed at tut work and 62 on tribute.

11,940. What is the number altogether of persons who are at work on the dressing floors?—There are altogether 167.

11,941. Are there many boys employed underground?—In Crelake there are none.

11,942. What kind of ore does your mine produce?—Copper and lead.

11,943. Is there any mundic with the copper?—Yes, pretty much mundic.

11,944. Is there so much that you sell it?—Yes.

11,945. What is the greatest depth of any level in your mine?—86 fathoms below the surface.

11,946. At how many levels are you working at the present time?—Seven levels.

11,947. Is the copper lode developed below the lead?—Yes; the lead lode runs north and south, and the copper east and west.

11,948. What is the country?—Killas.

11,949. Both for lead and copper?—Yes.

11,950. Is there any difference in the temperature of the levels where the lead and the copper are being worked?—Yes; there is a great deal of difference in the temperature of the level where the copper is. The copper is very much warmer than the lead. I mean that at the same level there is a difference; it is not so damp nor so cold in a copper mine as in a lead mine.

11,951. Is there any difference in the air in the levels where the copper is being worked and in the levels where the lead is?—I think it is about the same. We have very good air in our mine all through.

11,952. Are there no close ends in the mine?—We have no close ends in the mine.

11,953. Has there never been a close end?—We have ends which are not so well ventilated for winzes, but we have air machines, so that the air is about the same.

11,954. How far do you drive from any winze or shaft?—We have never driven, I think, beyond 40 fathoms; in the lead mine we have driven, I think, something like 80 fathoms, but there we have an air machine.

11,955. Is the air machine employed to force in air or to take out the foul air?—It is used for forcing in air.

11,956. Did you ever try a machine for the purpose of drawing out the foul air?—We have not.

11,957. Is it your opinion that forcing in air is the best means of ventilating?—I have never tried the other.

11,958. Do you find that the plan of forcing in air is quite efficient?—Yes, we do. We have always applied the pumping engine to force it in. We do not use water generally. We have a machine attached to the pumping engine.

11,959. Do you force the air down the shaft through pipes?—We apply the air machine at about the same level, or a little above the same level.

11,960. The air you take is near the shaft, but on the same level?—It is from the shaft, but near the same level.

11,961. The machine is worked by the engine?—Yes.

11,962. Have you ever ascertained the difference of time that it takes to get the powder smoke out of a level by employing the machine, and when it is not employed?—I have never tried the difference as to the length of time.

11,963. How long should you say the smoke was in clearing out of a level that has been driven 40 fathoms without a machine?—It lies a considerable time in some instances, but there is no machine where the levels are driven a great distance; they are not without communication.

11,964. Before you put in the machine, which is now working, do you know how long the smoke was going out?—No; I never timed it in order to see how long it was, but it has lain there for a considerable time before the miners could go into work.

11,965. How soon is it driven out now?—In about 10 minutes before the men can go in again.

11,966. How long is it before it is completely cleared away?—Perhaps half an hour before it is cleared away altogether, but it is cooled down now so that the men can go in in about 10 minutes.

11,967. Is there no end or place in your mine where

the miners are obliged to hold the candle on one side in order that it may burn ?—Not one.

11,968. How long have you had the management of the mine ?—About two years now come next September.

11,969. You have not had any end in which the candle would not burn freely upright ?—Not in our mine.

11,970. How do you know when it is necessary to apply the machine ?—We can tell that by the draught and the smell ; the air is not so good.

11,971. Do you judge of that or do the men judge of it ?—We can always detect that without the men saying anything ; of course the men will make mention of it if they find that the air is not satisfactory to them, and we then apply the air machine.

11,972. Yon can judge of that by your own inspection ?—Yes.

11,973. Have you ever known any of the miners to suffer from working in those ends ?—I have known men to suffer, but not in Crelake.

11,974. Have any accidents ever occurred in your mine under your present employers ?—There was one fatal one.

11,975. From what cause did that arise ?—It was a piece of ground which fell from the side. The men were preparing to put in a piece of timber ; in fact, they left it in. It did not fit the place exactly, and they took it down, and there was a fault or a wall that they did not happen to see, of about six inches, and a ton of stuff came down and killed a man on the spot.

11,976. Has there been any accident from blasting ? —Not one.

11,977. Do you think there is no danger from blasting ?—Not when it is properly attended to.

11,978. Do you adopt any precautions different from those taken in other mines to prevent accidents ? —No ; we use the safety fuze.

11,979. Do you not use cartridges ?—We use no cartridges ; our ground is very soft, and we do not use a large quantity of powder.

11,980. Do the miners work with the pick ?—More especially.

11,981. Does not that occasion a great deal of dust ? —Not generally.

11,982. But there is some dust ?—Yes, but not more dust than there would be by boring and blasting.

11,983. Do you think that there would be as much dust by boring and blasting?—Yes, generally speaking. It would depend upon whether the ground is very dry or damp. In our mine the ends are a little damp, weepy, not wet so as to injure the men.

11,984. Do these observations apply to both copper and lead ?—More especially to lead as to the dampness.

11,985. It is drier in the copper ?—Yes ; and we blast a little more in the copper.

11,986. What quantity of candles do you allow to each man per week ?—We allow 3 lbs. a week per man.

11,987. What is the charge that you make for the candles ?—In Crelake we charge 9*d.* for powder and candles.

11,988. What is the charge made for club money ? —9*d.* per man for doctor and 9*d.* for club.

11,989. Is the club money for the relief of miners who are suffering from visible hurts, or for sickness ? —For visible hurts. We do not allow any sick-pay in our mines.

11,990. Do you keep a distinct account of the club money ?—Yes.

11,991. Is that account rendered to the adventurers ? —Not of the club money ; that is a distinct account.

11,992. It is not rendered in your general accounts, but is it included in the cost ?—That is deducted ; the club account is kept separate from the cost.

11,993. What amount of club money have you in hand ?—I think the club is rather over 100*l.*

11,994. I suppose, if there are no visible hurts to provide for, the club money increases ?—Yes. In a case of serious illness, or if a man should have a very heavy affliction, and has worked long in the mine, having a very heavy family, our rules allow the agent to make an allowance in an extreme case of that kind.

11,995. Are there any miners on the club now ?—There is one, he had been abroad and returned ; I think he was not in sound health ; he has worked in our mine, and I think he is affected on the chest.

11,996. What allowance do you make to this man ? —1*l.* per month.

11,997. (*Mr. Holland.*) But that is discretionary, is it not ?—Yes.

11,998. (*Chairman.*) How long should you continue to make that allowance to the miner ?—He has had it already some 8 or 9 months.

11,999. For how long should you feel justified in continuing it to him ?—I cannot tell how long we shall continue it ; he has a son working in the mine.

12,000. How many doctors are there to attend to your mine ?—We have four doctors.

12,001. Does the 9*d.* which is contributed by each miner include attendance on his family, or only on the man himself ?—Himself and family till they reach 14 years of age ; then they are supposed to pay their own doctor.

12,002. Can the men chose which of the four doctors they will go to ?—Yes.

12,003. Could they go to any other doctor, and yet receive pay from the club ?—We have a doctor's book, and the men come in and put down as to what doctor they wish to pay, and then we keep an exact account; they mention one, and then that money is charged to that doctor.

12,004. Might it be any other doctor than either of the four attached to the mine ?—Whatever doctor the miner chooses.

12,005. Do you think that that is sufficient remuneration for the doctor ?—They never complain of it ; they are always satisfied with the 9*d.*

12,006. And the men are satisfied if they obtain the assistance of the doctor whom they prefer ?—Yes, quite so.

12,007. On pay day, what proportion of notes and gold and silver do you obtain from the bank to pay the men ?—We mostly get change which is suitable to paying the men, without giving them any trouble.

12,008. No objection is made at the bank to give you what proportion of gold and silver you like ?—Never in any instance ; we state whether we prefer gold and silver, and they meet our wishes.

12,009. At the other small mine to which you have referred, how many men are employed ?—I think there are about 42 miners at work.

12,010. What is the deepest level that has been reached in that small mine ?—36 fathoms below the surface.

12,011. Is the water pumped out by steam power ? —Yes.

12,012. Is steam power also employed in the Crelake mine ?—Yes.

12,013. How many boilers are there at the Crelake mine ?—Three. There are three engines ; one is at some distance from the others ; that is worked by one boiler, and two boilers are connected, and twe engines are worked from them.

12,014. How often are the boilers cleaned out ?—Every three months.

12,015. Do they fail much ?—Not much ; that is, two of them. We clean out one every month, and blow it out every week ; the water is a little more foul there. We have a great blow pipe, and we blow it out every week.

12,016. As a rule, is that regularly done ?—Yes.

12,017. Have you any means of ascertaining the amount of water in a boiler besides the stop cocks; do you use a glass tube ?—Nothing but the gauge pipes.

12,018. How many safety valves are there to the boilers ?—We have one upon each boiler.

TAVISTOCK.

Mr. W. Shewis.

12 Aug. 1862.

12,019. Is the air at 36 fathoms below the surface always quite good ?—It is very good.

12,020. Is it a lead or a tin mine ?—A tin mine.

12,021. Is it in killas or in granite ?—In granite.

12,022. How far are you working in that level from any winze or shaft ?—Not above 20 fathoms.

12,023. How many shafts are there ?—There are two shafts on each lode ; they are working on two distinct lodes there, and we have also an adit level brought in on each level besides the two shafts.

12,024. Is there no place where the candle will not burn, or where you have discovered any poor air ?—Not there.

12,025. (*Mr. Holland.*) Is there any difference in the air in the granite and in the killas ?—There is more cold damp in the granite than in the killas; it is colder.

12,026. Are you speaking of the same depth ?—Yes.

12,027. Can you at all explain that ?—Not in any other way than that the granite is generally damper and colder than the killas.

12,028. Is it not naturally drier ?—It is always more damp in the stone.

12,029. There is not more water in the granite than in the killas ?—Not so much.

12,030. Then I presume you use the term "damp" in another sense from wet ?—Yes.

12,031. There is more damp, but you do not know why ?—No; it is cold and damp.

12,032. You have stated that you use air engines whenever the air is at all close ?—Yes.

12,033. Do you consider that the air-engine pays ?—Yes.

12,034. Can you furnish the Commission with any estimate of the saving in the air engine ?—In some instances probably it would be half ; it would depend upon how bad the air was, and upon whether an end was very close.

12,035. How much does it cost to work an air-engine —1*l.* a month ?—In working it with the pumping engine 1*l.* a month would more than pay it. If we worked the engine by hand, and employed boys to do it by hand, it would perhaps take 3*l.* or 4*l.* a month.

12,036. Suppose it cost 3*l.* or 4*l.* a month to work it by hand, would it yet pay by the saving that would be effected in the driving ?—Yes, the saving would be more than three times that.

12,037. In every case in which there is a palpable deficiency of good air without the use of an engine, it would pay to put one in, although it would cost 3*l.* or 4*l.* a month to work it ?—Yes, it would pay well then. You cannot work at all without them in some instances.

12,038. I suppose when you can work an air-engine with the pumping rods, it is a very small expense ?—The expense then is a mere trifle ; when you can attach it to the pumping engine it can scarcely then be considered any expense. In some instances you have an opportunity of putting in a waterfall at no expense.

12,039. Which would be the cheapest, a waterfall or an air-engine worked by the pumping rods ?—The waterfall would be the cheapest. It depenes upon the circumstances. If the water must go down the shaft then it would be a little cheaper.

12,040. If the water could run away by the adit it would be hardly any cost at all ?—It would be cheaper to work with steam power.

The witness withdrew.

Mr. WILLIAM GODDAN examined.

Mr. W. Goddan.

12,041. (*Chairman.*) Of what mine have you charge ?—North Wheal Robert.

12,042. Are you the underground agent ?—Yes.

12,043. What kind of ore does the mine produce ?—Yellow ore.

12,044. Is there any tin ?—We have not returned any tin yet.

12,045. Is there much mundic in it ?—Not a great deal.

12,046. What number of men are there employed underground in your mine ?—About 95 altogether ; 85 miners, that is 65 men and about 20 boys, tut-workmen and tributors.

12,047. What is the greatest depth of any level at which you are working ?—80 fathoms ; that is the western mine.

12,048. What is the greatest depth that you have reached in the other mine ?—62 fathoms.

12,049. Do the miners ascend by ladders ?—Yes.

12,050. How far are you driving in any of the levels from any winze or shaft ?—The bottom level which is 80 west of the trial shaft is about 65 fathoms from the shaft.

12,051. How far is it from a winze ?—There is no winze between it and the shaft.

12,052. By what means do you ventilate ?—We have very good air there.

12,053. Do you ventilate at all by artificial means ?—No.

12,054. The air is sufficiently good without that ?—Yes.

12,055. Do the candles always burn freely there ?—Yes, very freely.

12,056. (*Mr. Holland.*) How high is the level ?—It is seven feet high ; the men are bound to carry it that height.

12,057. (*Chairman.*) How broad is it?—From four feet and a half to five feet.

12,058. How many men work in that level ?—Only one pair, to be at work.

12,059. Have they never complained of the air because it was poor ?—No.

12,060. How long is the powder smoke in clearing away ?—We use Davey's new patent powder, and you see it go in about five minutes after you have fired a hole.

12,061. How long is it in clearing away altogether ?—The men tram their own stuff ; and when they have been out with two waggons of stuff, or when they have cleared the end out from boring the hole, then the smoke has gone from the end and goes away back to the level.

12,062. Are there two shafts in the part of the mine you are now speaking of ?—Two shafts.

12,063. Does the air go up or down that shaft ?—It generally plays up the trial shaft ; that shaft is about four fathoms higher than the eastern shaft. It comes down the eastern shaft, and plays in the adit level about half a mile east of the eastern shaft.

12,064. Does it change with the wind ?—Yes, when the wind is north-west as well as the other may occasionally ; not very often.

12,065. Then it comes down the trial shaft ?—Yes.

12,066. (*Mr. Holland.*) When the wind is in any of the other quarters, does it go the other way?—Yes, always.

12,067. (*Chairman.*) When there is not much wind moving, and it is a very hot day, what happens then ?—The eastern mine is ventilated. The eastern shaft, where there is the 60 fathom level, is about 290 fathoms east of the trial shaft.

12,068. Do you mean that the eastern mine is connected at the 60-fathom level; the trial shaft being the deepest, going down to the 80 fathom level ; and that the air comes down from the 60 fathom level, and also from the adit level ?—Yes.

12,069. And passes up the trial shaft where there is the 80-fathom level ?—Yes ; it goes to the 80, and then comes up.

12,070. You have a communication on the course of the lode with another mine at the 60 fathoms ?—Yes.

12,071. How low have you had the management of this mine ?—I have been there six years.

12,072. During that time have you never known an

end so close that the candle would not burn upright? —Never.

12,073. Have you never felt any inconvenience ?—No.

12,074. (*Mr. Holland.*) Is there any perceptible draught at the 60 fathom level ?—Yes; a strong draught.

12,075. Does it ever come to the bottom and go out at the top ?—Yes.

12,076. At the end of the level that is driven 65 fathoms at the 80-fathom level, do you perceive any motion in the candle ?—Yes, great motion; it goes towards the end.

12,077. Is the level holed through ?—No; the air plays back again; it plays in towards the end. The air goes in at the bottom of the level and back on the upper part of the level.

12,078. (*Chairman.*) At what height from the ground is the candle placed where that effect is produced ?—About half way down the level.

12,079. Have you ever tried where the back draught is?—No.

12,080. Is it usual at an end, at such a distance from the shaft, to have an inward draught of the kind which you have mentioned ?—No, not very common.

12,081. Then this is an exceptional case ?—Yes; I think it is.

12,082. Can you account for it in any way ?—No, not by any means.

12,083. Has the attention of the manager of the mine been drawn to it ?—No.

12,084. You did not think it worth while to draw his attention to it ?—No; so long as the men do not complain of the air.

12,085. What allowance of candles do the men get per week ?—We allow them three pounds a week for the two.

12,086. What is the price of the candles charged to them ?—8*d.* a pound.

12,087. Is the powder small grained or large grained ?—Large grained.

12,088. How much is charged to the men ?—8*d.*

12,089. What is the amount paid for club money ?—9*d.* club and 9*d.* doctor; 1*s.* 6*d.* a month.

12,090. Is club money for visible hurt or for sickness ?—We allow no sick pay, only for visible hurt.

12,091. Do you keep a separate account of the club-money ?—Yes.

12,092. Is it rendered in the accounts of the adventurers ?—Yes.

12,093. Do you know what balance there is ?—No.

12,094. Have you any men now on pay from the club ?—No.

12,095. Have you had any accident at your mine since you have been there ?—We have had two accidents: a boy killed and a man; they were both miners.

12,096. What was the cause of the accident ?—One was through a stone turning out of the side, and a little boy fell in a pass at the back of the 30-fathom level.

12,097. Did he fall to another level ?—Not right in the level; he fell about seven fathoms in the pass; he came down on the stuff.

12,098. How was the man killed ?—He was killed in the back of the 42-fathom level, the ground fell on him, the country came away.

12,099. Have you had any accidents from blasting ?—No.

12,100. Do you use any particular means for blasting besides the safety fuse ?—No.

12,101. No artridges ?—No, we generally make paper bags.

12,102. You make a paper cartridge ?—Yes.

12,103. Do you always use that ?—Yes.

12,104. The men make no objection to that ?—Not at all, they like it better than Copeland's cartridges.

12,105. Do they like it better than loose powder ?—Yes, we could not shoot with dry powder unless we made bags with paper.

12,106. Do you never shoot with loose powder ?—Yes, in dry ground.

12,107. It is only in wet ground that you use the paper ?—Yes.

12,108. (*Mr. Holland.*) Do you prefer powder to bags in dry ground ?—Yes.

12,109. Why ?—Because the paper takes up more room in the hole; we cannot get the charge to the bottom.

12,110. (*Chairman.*) How many doctors have you to the mine ?—The men are allowed to choose their own doctor; we take down the names and they pay 9*d.* a month.

12,111. Are the doctors satisfied with that mode of payment ?—Yes.

12,112. (*Mr. Holland.*) Can the men choose any doctor whatever ?—Any doctor whatever, whom the men like to choose.

12,113. They are not appointed by the mine at all ?—They are not.

12,114. (*Chairman.*) When the men join they name what doctor they wish to attend them ?—We do that every two months, or every month if they like; the men would sooner have it in that way.

12,115. (*Mr. Holland.*) Do the men choose as well as you could choose for them ?—Better.

12,116. Do they choose the best doctors in the place ?—I think they do.

12,117. (*Chairman.*) Have you any charge for the barber here ?—No.

12,118. Do you work your boilers with steam or with water power ?—We have one 30-inch engine in the western mine.

12,119. (*Mr. Holland.*) How many boilers ?—One boiler.

12,120. Is that for a pumping engine ?—Yes.

12,121. How do you manage when you have to clean it, have you to stop when you clean it ?—Yes.

12,122. Does the mine get drowned ?—No, our water is very easy.

12,123. If there was much water you must have two boilers ?—Yes.

12,124. How often have you to clean your boiler ?—We generally clean it every six or eight months.

12,125. Have you clean water ?—Yes, for condensing.

12,126. There is no copper in it ?—Not at all.

12,127. Have you a gauge pipe to show the depth of water in the boiler ?—No glass pipe, but two cocks.

12,128. Do you not think that a gauge pipe would be a good thing ?—As long as the engine man minds the taps it does very well.

12,129. Would it not be an improvement to have a glass water gauge ?—It certainly would be an improvement.

12,130. (*Chairman.*) On pay day do you know what proportion of notes and change you get ?—No; we have always plenty of change; no notes. All the money paid to labourers in gold and silver.

12,131. You pay the men more in change than in notes ?—Yes; all in change.

12,132. And the bankers make no objection to supplying change ?—Not at all, and we generally pay between one and two o'clock.

12,133. I suppose that the men have always a month in hand kept from them ?—Yes.

12,134. Why is that ?—I do not know. It is a general rule with mines. If there should be any disagreement about the money, we should have a balance due to the men.

12,135. But with tut-work men there is no reason except that why they should not be paid oftener ?—No.

12,136. For drawing your stuff do you use a kibble or a skip ?—At the western mine we use a skip and at the eastern mine a kibble.

12,137. Which is the most economical ?—The skip.

12,138. Why then is it not introduced in the other mine ?—Because it is a perpendicular shaft and skips

TAVISTOCK.

Mr. W. Goddan.

12 Aug. 1862.

are not necessary. A trial shaft is sunk in the course of the lode 80 fathoms.

12,139. (*Mr. Holland.*) How much is the underlie ?—About 20 inches in a fathom ; the other shaft is perpendicular.

12,140. You have a skip in the underlie shaft, and a kibble in the perpendicular shaft ?—Yes.

12,141. (*Chairman.*) Is there any reason why the skip should not be put into the perpendicular shaft if you had guide rods ?—None whatever.

12,142. And if it was cheaper it might be advisable to do it ?—Yes, the skip is the best.

12,143. You consider that the skip is the cheapest and best ?—Yes, and the safest.

12,144. Do you use chain or wire rope ?—A chain at the western mine, and the same at the eastern mine, but we have a wire rope to put in at the eastern mine when we think that the chain is getting poor.

12,145. You think that a wire rope will answer ?—Yes, with a large sheave.

12,146. (*Mr. Holland.*) You do not lift your men in the skip ?—No.

12,147. Would you like to do it ?—No.

12,148. Why ?—It is a very easy road as it is.

12,149. I suppose that they get up in ten minutes, do they not ?—Yes, in about that.

The witness withdrew.

Adjourned.

Note.—The evidence subsequently taken at Tavistock will be found at page 439.

FURNESS ABBEY.

Tuesday, September 30th 1862.

PRESENT :

The Right Hon. Lord KINNAIRD, K.T.
NICHOLAS KENDALL, Esq., M.P.
H. AUSTIN BRUCE, Esq., M.P.
RICHARD DAVEY, Esq., M.P.
P. H. HOLLAND, Esq.

The Right Hon. Lord KINNAIRD, K.T. in the Chair.

THOMAS ROPER, Esq., examined.

FURNESS ABBEY.

T. Roper, Esq.

30 Sept. 1862.

12,150. (*Chairman.*) I believe that you have an interest in some of the mines in this neighbourhood ?—Yes; in the firm of Harrison Ainslie and Company.

12,151. What is the name of the mines ?—Lindale Moor.

12,152. Any other ?—Whitriggs; that is half way between Dalton and Ulverstone.

12,153. What is the total number of men employed in those two mines ?—Men and boys, 490.

12,154. Out of that number, how many work underground ?—I should think about 400. Our mining agent will correct anything of that sort which I state wrongly. Our mines are situated between Pennington and Lindale.

12,155. What description of ore do you raise at Lindale Moor ? — Hematite ore. Harrison Ainslie and Company are the oldest miners of the country, and the mining interest here has only been of recent standing ; 25 years ago it was very small in comparison with what it is now; at that time the mines were almost entirely in our hands, that is to say Harrison Ainslie and Company, who have existed as a firm above 100 years.

12,156. The increase in the mining district has taken place within the last few years ?—25 years; in fact since the cutting of this railway.

12,157. (*Mr. Austin Bruce.*) When you speak of the district do you mean the whole of this district in Furness ?—Yes ; plain Furness we call the mining district, from Ulverstone all the way down to Barrow.

12,158. (*Chairman.*) What bargains are made with the men ; do they work in parties ? Yes.

12,159. What number are there in each party ?—It very much depends upon the particular part of the mine; the veins of ore are uncertain in their breadths, and require different ways of working ; we sometimes let them work by the fathom, and sometimes by the ton. Our underground agent is a man who worked at the mines himself; his father was our mine manager till his death, and this young man, an intelligent workman, has a practical acquaintance with the value of work, both above ground and under ground, and he, advised of course by Mr. Ainslie lets all these jobs.

12,160. Does he settle the price, or is it let by competition ?—Scarcely by competition ; certain men are wedded to certain mines, they have, perhaps, opened them at first, and they do not like to be disturbed from that shaft or shafts ; the job is generally let to the men who are best acquainted with that particular shaft and locality.

12,161. And you trust to this agent ?—Greatly.

12,162. There is no public letting ?—No.

12,163. What is the average price per ton where they work per ton ?—That is regulated very much by the rate of wages in the district at the time. We want every man to earn so much money per day, and the underground manager calculates that if he gives so much per ton for his mine, the men have the power easily to earn these wages, and if they work well and skilfully, they will earn more.

12,164. You say "these wages;" about what amount do you consider that a man ought to earn in making these calculations ?—At present the wages of the district average 19*s.* or 20*s.* per week ; a day is eight hours, and on Saturday four hours, and in that time a man ought to be able easily to earn that amount.

12,165. Do they work in shifts ? — Yes, sometimes.

12,166. Have you any night shifts ?—Very few ; all our ore is more or less mixed with little dirty particles of clay, and if it were got at night time and thrown out on the heap, the clay would never be picked out. We have women, old men, and boys employed picking the ore, and if they had not daylight to pick it the ore would become dirty, so that we at all times avoid night-work if we can on that account.

12,167. (*Mr. Holland.*) Is it necessary to pick it immediately ?—Yes.

12,168. (*Chairman.*) Are not the workings also loaded direct from the shaft ?—No, it is a small waggon which lifts the ore, and it is tipped into a larger waggon, and the pickers are employed in the larger waggon, and that larger waggon is again tipped into the railway waggon.

12,169. Are the persons who are employed in picking under cover or not ? — Very seldom under cover.

12,170. Are the men also paid by the fathom or by the yard ?—By the fathom.

12,171. Is there any particular term for the men

who work by the fathom?—I think that they are generally called undertakers.

12,172. What are the deductions which are made in the gross payment of the men?—In our own mines we have 3*d.* per week from each man, which goes to the maintenance of a doctor to attend all their cases, and to the education of all the children. Besides that fund of 3*d.* per week, there are subscriptions which each partner individually in our concern makes, and the neighbouring mine owners whose children are likely to come to our school, also assist in maintaining the school.

12,173. Does the 3*d.* include the attendance of the doctor on the family as well as on the men?—We pay 95*l.* a year to the surgeon, and he has to attend all the miners whenever called upon, and if he is calling at a mining village, and any of the women or children belonging to any of our miners want advice or medicine he gives it, but he is not called upon to go to them specially.

12,174. (*Mr. Austin Bruce.*) Does he provide medicine out of the 95*l.*?—Yes.

12,175. (*Chairman.*) And this is for all descriptions of illness as well as accident?—Yes. Our agent will read the rules of the mines if you require it. We have a rule that a man would be fined if he absented himself from his work on the plea of illness, unless that illness was certified by the doctor.

12,176. What is the name of the medical man?—John Crank.

12,177. (*Mr. Austin Bruce.*) I suppose that he attends other works as well as yours?—Not as the regular surgeon of the works, I think; he and his partner are at the head of the profession in this district.

12,178. (*Chairman.*) Where does he reside?—At Ulverstone.

12,179. How are the men paid; are they paid in notes, or in gold, or in silver?—We pay fortnightly; each man will not earn more than 2*l.*; he is paid in gold and silver.

12,180. Do you pay the head man of the undertakers?—Our underground agent will explain it, I think, in this way; there are ten interested in a bargain, the time of each man is kept by the time-keeper, by the captain of the particular mine, not by the undertaker; he gives in the time and at the fortnightly pay we pay each man his 3*s.* a day if that be the regular wage of the week or month or year. The mine is got by the ton; the money calculated out will amount to more than these wages amount to, one more comes in and gets the balance, which balance he divides amongst his men.

12,181. So that a certain amount of wages is paid to each man?—Yes, every man working on the mines gets a certain wage, and then he gets his share of the balance according to the value which the undertakers themselves place upon each man's work I suppose; we do not control the balance.

12,182. (*Mr. Austin Bruce.*) Is there a payment on account till the whole is measured up?—No, every fortnight concludes itself, we keep what is called in this country an on-ligging week, that is to say, a week in arrear, so that it gives time to calculate all this.

12,183. (*Chairman.*) You have one week in hand?—Yes, always, every fortnight.

12,184. (*Mr. Davey.*) Do you pay every man his money separately?—Yes, and either Mr. Ainslie or myself, or both, is always present at the pay. We pay in gold and silver. Saturday was our last pay, 935*l.* was paid, 30*l.* of which I paid in notes for candles, and the rest was in gold and silver.

12,185. (*Chairman.*) I have asked you as to deductions; what other deductions are there besides the club or doctor?—You can imagine that eight men are essential to perform a certain work; if one man is absent when the other men are ready to go to their work, that man is fined; that is a deduction.

12,186. Is the work done at all by blasting in your mine?—A good deal.

12,187. Have you any accidents from blasting?—Very rarely. One man last year I think burnt his face; he is at work again.

12,188. Did you ascertain how that happened?—From some careless tamping I think.

12,189. Do the men generally reside near the mine, or at a great distance from it?—The greatest distance will be Ulverstone.

12,190. (*Mr. Austin Bruce.*) How far is that?—Two miles by the path which they take; they take the footpath.

12,191. (*Chairman.*) Do the men change their clothes when they come up from the mine?—Not always; it used never to be the case.

12,192. But they do so sometimes?—Yes, they have the liberty to do it.

12,193. Is there any place for them to change in, called a changing house?—Every pit has a boiler, and the men are allowed to change in the boiler-house; there is no place built on purpose.

12,194. Are the men who work in your mines liable to any peculiar disorder?—No. The iron mines are peculiarly healthy, working in hematite ore.

12,195. (*Mr. Austin Bruce.*) What is the annual produce of your mines?—It averages 140,000 tons in the last five years.

12,196. You mentioned that you employed 490 men and boys; how many women do you employ?—I should include the women amongst the boys; we have five women I think.

12,197. Exclusively for picking?—Altogether for picking; they are generally the widows of miners.

12,198. What wages do the 90 out-door people get?—2*s.* 7*d.* and 2*s.* 9*d.* per day, according to their value.

12,199. Does that apply to the women?—No; I am speaking now of the labourers outside.

12,200. What do the boys and women engaged in the picking get?—1*s.* and 1*s.* 3*d.* a day.

12,201. You say that you let the working of the ore by contract to the men; does one man take it and employ other labourers under him at day's wages?—No; we always know who will form a company of undertakers; the bargain may be with two, but we know that there are four others who are sure to be working with them.

12,202. Are those four others paid by day's labour, or do they share in the contract?—They share in the contract; there are a certain number of the miners who share in the contract.

12,203. Then in fact there are more working at day labour?—Yes, underground; our mining agent will tell you exactly how that is; there are a certain number who get days wages both above ground and below.

12,204. To what accidents are the men subject in the works?—There have been accidents of this sort; men repairing a shaft, standing on a plank, striking and missing the blow when aiming at the wood, and striking the plank from under them, and going down; there have been no accidents I think from machinery in our pits, except one.

12,205. Have there been any accidents from the fall of the mine, or of the roof?—No, all our mines are supported with larch timber; larch will give notice by cracking and splitting, and so on, before any danger can accrue; we have never had an instance of that sort.

12,206. Are there any of those accidents which frequently happen in a large coal mine from a large mass coming down?—Very rarely.

12,207. As one of the partners, have you any complaints from the men of the want of those conveniences or securities for life or health which it is the duty of a master to furnish?—I have never heard of such a thing; we superintend the people; our object being always to be there, so that if a man has a complaint of any sort, he has his master to apply to.

12,208. Have you lived all your life in this district?—Very nearly.

12,209. Do you observe any difference between the

Furness Abbey.

T. Roper, Esq.

30 Sept. 1862.

physical appearance of the men employed underground, and of the agricultural labourers ?—No ; I fancy that we have the better of it.

12,210. You consider that the higher rate of wages which your men get, and their better feeding compensate for any unhealthy effect from working underground ?—I never heard of it complained of as unhealthy ; it very frequently occurs that farm labourers come to us.

12,211. You consider the health of miners to be as good and the life as long as of those who work underground ?—Certainly.

12,212. Does that observation apply generally to the mining district ?—Of course I know more of our own men than of any others, but I should say all through the district.

12,213. (*Mr. Davey*). Do you open your mine by driving a gallery from the bottom or how is it generally worked ?—A shaft is sunk and generally on what we call the south side of the vein,—it is really west or nearly west, the miners have got the habit of calling one side north and the other south, north rock and south rock,—and we sink a shaft into the south rock and drive across the vein to the north rock.

12,214. Have you any level communicating from there to the bottom of the hill called an adit level ?—There are two such levels in our mines, we call them day levels.

12,215. What size are your veins generally ?—Very variable in width, we have the vein 50 feet and we have it 5 feet, there is an alternation, there are pockets as we call them, narrow places here and there where the two rocks seem to come together again.

12,216. How do you keep the sides from falling in ?—With two pieces of larch very nearly the size of a railway sleeper, the trunk of a tree from which you would cut a railway sleeper, and a piece of equal strength on the top ; the upright parts are called the forks because of their being forked a little, and the other is called the head tree and it rests on the forks.

12,217. Do you work at all under the day level ?—No.

12,218. Have you any steam engine for the purpose of drawing the water ?—Yes, we have 14 steam engines all drawing water, either by pumping or by lifting in buckets.

12,219. They are not connected with the day level ? No ; our two levels having been driven some years ago the workings have got below them and they are only useful to take the air during summer.

12,220. Is your ventilation very good ?—Very good generally ; there is very rarely any complaint ; we hear a complaint in very sultry weather ; when there is very little current in the upper air, the air below gets tainted and foul.

12,221. What means have you of improving ventilation at any time ?—Most of our mines are connected one with the other so that the one operates as a down shaft and the other as an up shaft. If, however, that is inoperative we employ a fan occasionally to blow the air down, a fan which we can move from one shaft to another. In many cases we employ a fire-pan, we fill a pan of a cylindrical shape made of open grating with quite dry wood, and when it is furiously burning we let it down the shaft by a chain and it will go down glowing.

12,222. (*Mr. Austin Bruce.*) That is down the upcast shaft ?—Yes.

12,223. (*Mr. Holland.*) About how far is the fire pan lowered ?—It depends upon how far the bad air has risen in the shaft.

12,224. About how deep is it generally lowered, 20 or 30 yards ?—Of course it must depend upon the depth of the shaft itself—40 yards or so.
we immediately set to work to remove this tainted air,

12,225. Is not it rather a weak draught if it is only 40 yards high ?—Perhaps I do not make myself quite understood ; the shaft or pit from which all the ore is drawn is 50 yards deep ; the men say that the air is tainted, and that they lose their light, and the moment they lose their light they come out of the place, add and we do it by letting this fire-pan down, and it goes down and down until it comes to the tainted air.

12,226. (*Mr. Davey.*) What is the effect then on the air ?—It creates a vacuum as it goes down, I imagine. The moment it comes into carbonic acid gas or anything which is more or less tainted with an excess of carbonic acid gas, there is nothing to support combustion, and the fire goes out. I do not know whether I am right or not, but when the pan is going down I imagine that it is creating a vacuum by its own consumption ; the air is perfectly still in the shaft. If there were a current in the shaft, if it were lively, it would not be required ; so that I imagine that this is a perfectly calm atmosphere where it is going down, and it removes the oxygen as it passes down and destroys a great amount of the volume of the air, and to supply the vacuum the heavier air rises, and after a while it comes out like a cloud ; it comes out perceptibly.

12,227. (*Mr. Austin Bruce.*) Then do you mean to say that the fire is not extinguished till all the bad air is removed ?—The fire-pan goes out, and we lift it again and ignite it again ; the second time it has not to go so far down the shaft, and so gradually.

12,228. (*Mr. Davey.*) Do you bring it up again to ignite it ?—Yes, and fill it again with wood, and it goes down so much less each time.

12,229. (*Mr. Austin Bruce.*) Has this operation to be performed often ?—No ; perhaps eight or ten times in a year.

12,230. (*Mr. Davey.*) I presume that you drive galleries in the ironstone ?—Yes, from the shaft.

12,231. After you get in a certain distance, how do you find the air ? how far can you drive without putting in a fan ?—That would depend upon the state of the atmosphere above. When you have a lively current above you can drive 20 or 30 yards, and have good air all the way. Most of the drifts will not be more than about 30 yards, and then they come back again towards the shaft.

12,232. (*Mr. Holland.*) Is the whole width of the ironstone bed 50 yards ?—Yes, sometimes.

The witness withdrew.

Mr. Robert Kendall examined.

Mr. R. Kendall.

12,233. (*Chairman.*) You are the agent or manager of the Lindale Moor mine ?—Yes.

12,234. And only of that mine ?—Only of Lindale Moor mine, and only under Harrison Ainslie and Company.

12,235. About how many men work under ground at the Lindale Moor mine ?—About 330 actually underground, and 100 connected with them about the pit heads and in sinking.

12,236. Does that include boys ?—No, we do not allow boys to go underground ; they are generally 18 or 19 years old before they are able to do underground work.

12,237. Do the men work in partnership ?—Generally in drifts or sometimes pits wholly together.

12,238. How many generally work in one drift ?—Generally about four, when they work double sets, two in each set.

12,239. What are their hours ?—Eight hours.

12,240. Do you ever work night shifts ?—Very seldom, unless it be on some very necessary occasion.

12,241. What is generally the size of the drifts ?—Our drifts are 8 feet by 8 ; when wood is put in it is 6 feet by 6 inside, when the drift is made new.

12,242. Have you any drifts driven for taking away the water or preparing for your lower workings ?—Yes, in some cases we have.

12,243. Which are the more difficult to ventilate, the lower drifts or the drifts where you are working ?

—The lower drift is more difficult to ventilate in general.

12,244. What means do you take to ventilate those lower drifts?—We contrive to make upright rises into an air drift and connect that by ventilation with another shaft.

12,245. What distance is there between the working drift and the drifts which you are driving for after working?—It just depends upon circumstances, provided we were putting down a shaft we might put it down 10, 12, or 15 feet lower than where we were driving.

12,246. And then you would put in a drift to join that shaft?—In some cases we do.

12,247. Do you adopt any artificial means of ventilation?—When we have not ventilation by a shaft, but by driving a level to meet one we generally apply a fan blast.

12,248. How is the fan blast worked?—By pipes down the shaft and blown from the surface.

12,249. By means of an engine?—No; we always employ hand labour for it, but that is only very temporary, just while we take one heading.

12,250. Does a man work it at the surface?—Yes; the man who attends to the fan blast.

12,251. He drives the air down the bottom of the shaft and then along the drift?—Yes.

12,252. Do you ever use water for that purpose?—No; we have never used water.

12,253. What is the pipe generally made of?—Generally of wood, but sometimes we have tin pipes. We have found that large wooden pipes answer better than smallish tin pipes.

12,254. Do you find that fully efficient to ventilate?—Yes; so long as we require it. I do not mean to say that it would do for a permanent thing, but in driving from one pit to another we should use that.

12,255. What should you say is the longest distance between one pit and another that you would think of driving?—I should think that 65 yards is a good distance to take in. We generally contrive to have our shafts 100 yards apart, and in some cases 60 yards, or just as it happens; but we are obliged to have shafts very near one another.

12,256. You have a great many shafts?—Yes; our ground is very treacherous. We have a dirty clay which squeezes, and our shafts do not last very long.

12,257. The shafts collapse?—Yes; we have very poor ground to work in. It is generally a swelling tough clay.

12,258. Have you any shafts which are specially downcast or specially upcast?—Yes; the nature of our ground generally allows that to be the case. The shafts which are in the lowest ground are generally downcast, and those in elevated ground upcast.

12,259. Are they not affected by the weather?—Very little then. If they are on level ground they are a good deal affected by the weather.

12,260. Supposing they are affected by the weather, what means do you adopt to create an upcast?—We generally put down an open fire-pan filled with chips and shavings, and when we have good air outside we generally succeed in getting a good draught.

12,261. Is it affected by the direction of the wind or by the want of wind?—It is generally by the want of wind. In sultry thundery weather it is worst. For instance, if there be a thunder storm rising we generally find the air affected by it.

12,262. (*Mr. Holland.*) When the external air is hot it spoils the draught?—Yes, in a great measure.

12,262*a*. Do you find a difficulty in stirring the air with the fire pan?—We never find a difficulty when we put fire-pans on.

12,263. (*Chairman.*) When do you consider it necessary to put fire-pans on?—When the draught is completely at a stand still and does not work either way.

12,264. How do you ascertain that that is necessary?—Because the candles will not burn.

12,265. Have you any other means of ascertaining it?—No.

12,266. Do the men feel the effect of it?—No; I have never known any man affected by what we call bad air, because the candle ceases burning. I have no doubt that if they remained for a length of time after the candles went out that might be the case, but I have not seen it in my experience.

12,267. Do the men leave the work as soon as the candles go out?—Yes; at once.

12,268. And they report to you?—Yes; or to one of our underground captains.

12,269. How many shafts have you through Lindale Moor mine?—We have 11 shafts working, and we have four sinking.

12,270. About what is the greatest distance that any of the drifts are driven?—We have some drifts at 100 yards from the shaft. That is the longest which we have; but we pass one or two air shafts in that distance.

12,271. In taking away the ore is the whole of it removed and is the ground supported by wood?—Yes.

12,272. Does the whole ground collapse after the ore is removed?—Yes. Our ground is so very weak and broken that it settles down.

12,273. Have you ever had an accident from the ground falling in from above?—No; I do not think that we have ever had one from that cause.

12,274. The stuff in which you have to work is not rock?—No.

12,275. (*Mr. Austin Bruce.*) What are you working in?—Our surface is generally pindle and clay and some small detached stones.

12,276. You are obliged to keep it up by artificial means?—By wood. We put in our wood as close as it can possibly be put.

12,277. (*Chairman.*) What is the distance between each row of cross bars?—We put them in two feet apart, and then put intermediate ones.

12,278. How do your men meet with accidents?—When we do meet with an accident I can scarcely say how it arises. The last accident which we had was on account of being drawn at the pit head by some little carelessness.

12,279. Have you ever had any accident by the stuff falling on the men?—No; I think that we have never had one in my recollection.

12,280. (*Mr. Holland.*) Is the crushing in of the timber a very slow process?—Yes; you cannot distinguish it.

12,281. (*Chairman.*) You have to put down the pan more than once to make the shaft act as an upcast, have you not?—If we have a good air course and two shafts are connected, which we generally contrive to have, it generally happens that the first fire-pan is sufficient, and that may continue for weeks and months, and the bad air not come in again.

12,282. The men work in parties, do they not?—Yes.

12,283. What allowance of candles do they get?—We find candles for them, and we allow them 2lbs. a week, which is quite sufficient, and if it be very good air weather they will save one or two, and if it be bad air weather so that the candles get soft and burn quicker, they have to find one or two themselves, and a very strong current will burn the candles faster; but we can regulate that by putting on doors so as to stop the ventilation.

12,284. Do you put on doors to regulate the ventilation?—Yes

12,285. What do they pay for the candles?—We do not charge them for candles; we find candles and tools for them; we give them sufficient candles to supply them, and if they be extravagant they have to make them up, and if they can spare one or two they can take them home.

12,286. Are the wicks of the candles made entirely of cotton?—Yes.

12,287. Where do the men change when they come to the surface?—Some men do not change at all,

they prefer going home, and some men are allowed to change on the boiler or in a part of the engine house, which is made on purpose; we have a good few men who have only a quarter of a mile or so to go home.

12,288. Have you a copy of the rules of the mines ?—Yes (*producing the same.*)

12,289. Do you give an order for any of the wives to get provisions ?—Yes; we give them subsist every week, so that they can get provisions at a store, and in some cases when it is actually needed we give money.

12,290. Does the store belong to the mine, or is it an independent shop ?—It is an independent shop.

12,291. And it is merely an order on that shop for such an amount of money ?—Yes.

12,292. (*Mr. Austin Bruce.*) You say that when the candles go out the men complain to you and you take methods for improving the ventilation ?—Yes.

12,293. Do you think that a man can work healthily and well in air, which, without actually putting out the candle makes the light weaker than it ought to be ?—I do not think that they can, and in fact, if it does not actually put the candles out, but there is a want of air, we apply some method to relieve them.

12,294. Do you ever apply these methods before the candles refuse to burn ?—Yes ; we always provide for them ; we have many cases where we gain ventilation without being subjected to the candles going out for want of air, but we always take this precaution to get our connections as quickly as we can.

12,295. Where, as a rule, is the ventilation weakest? —If we have cut air courses I do not know that there is any such bad air, but it generally happens that when we have no air courses, and are driving in among old workings for connections with another shaft we find the air worst there.

12,296. And you then introduce artificial ventilation ?—Yes.

12,297. What do you mean by "air courses" in your last answer ?—By air courses I mean one shaft being connected with another, so that air can go between one and another.

12,298. Are all those courses 6 feet by 6 ?—Yes ; when they are first made, but they gradually get closer and closer, and we have sometimes another air course going on at the same time when this is at work, it requires that on account of our bad ground.

12,299. Does it ever happen to you, when you have received a complaint that the ventilation is bad, although the candles are not actually put out, to examine the ventilation and to find that the complaint is unreasonable and unnecessary ?—I have never had a complaint to me where it has not been reasonable and necessary, for I generally keep a very strict control, as regards ventilation, and I do not allow the men to go to work there if the ventilation be not good; if it be bad we always contrive to improve it by artificial means or by air courses.

12,300. Did I rightly understand you to say that none of your drifts are driven more than 100 yards from a shaft ?—Yes, I did say so.

12,301. Then your shafts are seldom very deep?— They are not very deep ; we have them from 60 to 80 yards, but we have some not so deep ; I think 90 yards is the deepest pit which we have.

12,302. Is your upcast always the same, or does it vary with the state of the external atmosphere ?—It sometimes varies, if the ground where the shaft is be on a level ; but if one shaft be put on to lower ground and the other on more elevated ground, we have the up-cast generally on the highest ground, if it stops we put the fire-pan on the highest ground.

12,303. Practically you do not find the ventilation in these mines to be a difficulty ?—No, I have never known men take hurt by want of ventilation.

12,304. Have you ever known men becoming ill in any way from the want of pure air below ?—No, I do not think that I have ever experienced it.

12,305. Do you sometimes use powder ?—Yes, a great quantity.

12,306. Is that in the ore itself, or in the rock ?— In both.

12,307. As a rule how soon does the smoke disappear after a blast ?—It sometimes remains perhaps 10 or 15 minutes, if it be dull heavy weather, and if it be a good sharp drying blast we have it out in less than five minutes.

12,308. (*Mr. Holland.*) Does it ever stop an hour ? —It is a very rare case if it stops an hour ; it might stop an hour in one of the courses which we are driving for an air course.

12,309. (*Mr. Austin Bruce.*) When it stops a long time do you find that the men go in before it is clear ? —No, they do not go in till they can see ; the smoke must die away before the men get to work again.

12,310. You have never known the men suffer from breathing the smoke ?—No, we always consider that it is rather healthy.

12,311. How does it happen that your ton is 33 cwt. ?—It is only just our weight that we let the men have it for ; our waggons which take it away are expected to hold 33 cwt., and if the waggon does not hold that it is so much taken off, it averages 33 cwt.

12,312. Do you allow the men to take away more than 33 cwt. ?—Yes, and whatever is sent more they are paid for it, and whatever is short we deduct.

12,313. Have you any trouble with the men on the question of weights ?—No, I do not think that we have ever had a question of that kind.

12,314. By whom is the weigher appointed ?—By the Duke's agent and ourselves.

12,315. Have the men anything to do with the appointment of the weigher ?—No, the men can go down to any machine and see the ore weighed if they choose, and they are paid exactly by the same weight as we pay our lordship by.

12,316. Up to what age do the men continue to work in your mines ?—We have some men working 60 years old I should think, and some a little older ; there may be some men of 65.

12,317. Underground ?—Yes.

12,318. I suppose that when they get unfit for underground work they sometimes get light jobs above ground ?—Yes, we always contrive to give them light jobs above, such as picking the ore.

12,319. Do you think that a man is able to work as many years at this underground work as he is at agricultural work ?—Yes, I believe that he is. I believe that, as far as his health is concerned, he is quite as able ; we have had men who have worked till they have been over 70, and have worked in mines the principal part of their lives.

12,320. At what age do you take boys ?—We take them about 16, and some rather below 16, just as the case may be.

12,321. Who is responsible for employing or refusing a boy ; is it you ?—I always take them. We do not take boys underground at 16 ; they begin to work underground about 17 or 18.

12,322. What is your reason for not allowing them to work underground before that age ?—Because they are worth nothing ; we have no work which is suitable for them ; we have not anything excepting rather heavier work than they are able to do till they come to that age.

12,323. Do all the children of your workmen go to school ?—They do, principally ; we have a good school close by the works, and a school at Orswick, and we have two schools at Ulverstone. I cannot exactly say what number go to the other schools.

12,324. Up to what age do they remain at school ? —We do not tie them to leave school at any particular age. I should think that they leave school at 14 or 15 years of age. We have had some very good scholars, and they have been over 15.

12,325. (*Chairman.*) Is something deducted from the wages of the men for the maintenance of the school, whether they have children or not ?—Yes, we charge 3*d.* a week for school and doctor.

12,326. (*Mr. Austin Bruce.*) Have you no employment for boys between 10 and 14 ?—There is very little at our place, excepting just picking some ore, and they are rather too small for that.

12,327. What is the age of the boys who are employed in picking ore ?—From 14 to 16.

12,328. (*Mr. Davey.*) I do not understand the manner in which you work the mine. After you have taken one drift away you sink how far ?—Eight feet is what we consider to be a sufficient drift.

12,329. You cannot drive through that and leave anything above ?—No, we take it all off as clean as we can.

12,330. You carry it away all before you?—Yes.

12,331. (*Mr. Austin Bruce.*) Have you a plan of your workings here ?—Yes (*producing the same*).

12,332. (*Chairman.*) With regard to the relief fund, how much a week do the men pay ?—3*d.* a week.

12,333. That is for school and doctor ?—Yes.

12,334. Is it for accident and illness ; whatever is the illness, are they attended by the doctor ?—Yes.

12,335. What allowance have they when they are ill ?—It is not a rule that we have to give them any allowance, but if we have any surplus money we give them something out of the school and doctor fund ; and if a man gets fined, which is very rare, but which sometimes happens, that money goes to the school and doctor fund. In some cases a man may leave his work for a day or two, and then what he forfeits goes to the school and doctor fund.

12,336. A separate account is kept of this fund ?—Yes, it is a separate fund altogether.

12,337. Are the receipts from the men sufficient to support it ?—No, it seldom pays for itself except in some cases with these fines being put to it, but whatever falls short Harrison Ainslie and Company make it up.

12,338. Does the doctor attend the men's families ?—No, he does not attend, but if any of the family will go to his surgery, he will give them advice and medicine free. He will attend men, but only men; but if he was passing through a village where they lived, he would call in if they asked him.

12,339. Have you any accidents from blasting ?—We have had an accident from blasting, but it is very rare ; we have had one accident from blasting this last year.

12,340. How did that happen ?—It was on account of leaving rather more fuse than a man ought to have done ; he was deceived in it, and he went to see the charge, and he thought that it was not going to explode, and it exploded before he was aware of it.

12,341. Do you always use the safety fuse ?—Yes.

12,342. (*Mr. Holland.*) Have you no rule that the men are not to come near the fuses till a certain time after firing ?—We give them instructions how long they are to remain. A fuse should travel such a distance in so much time, and this accident was on account of the man's being mistaken as to the length of his fuse.

12,343. Do you not allow a long interval to elapse ?—Yes, it should be so.

12,344. An hour or two ?—We can not always watch a man.

12,345. Have you no such rule ?—No, we have not a rule for it.

12,346. (*Mr. Davey.*) You stated that your deepest shaft was about 90 yards ?—Yes.

12,347. Do you still continue to sink that ?—Yes ; as soon as we get that ore out we shall sink it deeper.

12,348 That does not come to the bottom of the ore ?—No, we have ore below that.

12,349. Have you any idea how far down the ore lasts ?—I do not know.

12,350. (*Mr. Austin Bruce.*) How do the men come out of the shaft ?—They ride up in cages.

12,351. Always ?—Yes.

12,352. (*Mr. Holland.*) What is the underlie ?—About 1 in 2.

12,353. What is the thickness of the bed ?—It varies ; I should think that it is about from 10 feet to 20 yards.

12,354. Are the workings very dry ?—In some places, they are not all very dry.

12,355. Do the men often get their clothes very wet ?—No.

12,356. Do they sweat very much ?—Yes.

12,357. So as to wet their clothes ?—They pull all their clothes off generally, excepting their drawers and working shirts.

12,358. Do those get wet with sweat ?—Their shirts get wet with sweat.

12,359. Do they go home in their wet shirts ?—No, they generally change ; if they do not change altogether, they have a dry shirt to put on underground ; they sometimes do that.

12,360. Is the air ever so bad as to prevent a man doing a fair day's work ?—No ; we have never had complaints from any men on account of bad air, that they could not do as much work as usual.

12,361. Is the amount of work which the men can do affected by the state of the air ?—No ; our shafts are so near together that we contrive to have them very well ventilated.

12,362. Do your men suffer much from cough ?—No, they are generally very healthy, except it be some of those parties who are naturally of an asthmatical tendency.

12,363. Have you many of them so ?—No.

12,364. Are there any diseases of the lungs among miners here which are called miners' diseases ?—No, I have never heard of any.

12,365. There is no disease known as a special miners' disease ?—No, I have never heard of such a thing.

12,366. You have spoken of men working at 60 years old or upwards ; is that considered unusual ?—No, we have several men at 60 and upwards who are working.

12,367. There is no remark made upon it, it is not thought extraordinary ?—No.

12,368. Are a large proportion of the people here employed in mining ?—I do not know the proportion.

The witness withdrew.

HENRY WILLIAM SCHNEIDER, Esq., examined.

12,369. (*Chairman.*) You have an interest in a good many mines in this district ?—Yes.

12,370. Will you state the different mines in the Furness district with which you are connected ?—Parks, Mousell, Newton, Whitriggs, and Old Hills.

12,371. Will you state about the total number of men in your employment ?—In round figures 460 are employed on the mines.

12,372. About how many of those are employed underground ?—About 250 underground.

12,373. What is the amount of produce of ore which these men raise ?—In round figures on the average of the last three years 260,000 tons per annum.

12,374. Which is your principal mine ?—Parks.

12,375. What is the deepest shaft at Parks ?—50 fathoms.

12,376. About how many shafts are there at Parks ?—There are 10 shafts at work at the present time besides the principal shaft.

12,377. How do the men ascend and descend ?—Entirely by ladders ; they are not allowed to ride in the cages.

12,378. You use the cages with the bogies for drawing the ore ?—Yes.

12,379. Therefore safety cages are not required ?—There are no safety cages, they are not required, and we are rather of opinion that greater care is exercised by the men under such circumstances in not using the safety cages ; that when they have them they are too

apt to rely upon them ; we have tried them in one instance, and it did not answer satisfactorily. If the men used them we should most decidedly adopt safety cages, because we think that it would not be right to allow the men to be exposed to any casualty which could possibly be avoided. The safety cages which we should adopt in the event of the men riding on the cages would be disengaging cages, which in the event of the rope breaking would remain suspended in the shaft, and so prevent their falling to the bottom. Also cages which would disengage on reaching a certain point to prevent their being drawn over the pulley, and immediately on the cage being disengaged the clutches would take effect, and the cage would remain suspended.

12,380. The men, you say, descend by ladder ways; are there ladder ways in the pumping shaft ?—Yes.

12,381. Are they fenced off?—Yes, from the pumps and from the drawing part.

12,382. Are there sollers at the bottom of every ladder ?—Yes.

12,383. So that a man falling from one would only fall to the next ?—He would only fall about 12 feet.

12,384. Are the ladders with wooden or iron spokes ? —Some have wooden and some have iron. In the winter near the surface we consider the iron staves very objectionable on account of the ice affecting them. We once very nearly had a serious accident on that account ; they are slippery.

12,385. The deepest shaft that men have to climb is 50 fathoms?—Yes, but the average depth of the present workings does not exceed 30 fathoms.

12,386. To what description of accident should you say that men are liable, any particular description of accident ?—The accident to which the men are most exposed is from rocks of ore dropping either from the end or top of the levels while they are in the act of either timbering or preparing the timber.

12,387. But when once the ground is timbered up it is safe ?—Yes ; we never have known an instance of any level suddenly giving way, although the crush upon the levels is enormous, so much so that a stick of timber nine inches in diameter has been known to be crushed in 24 hours ; still it is gradual and it never entirely closes up the level.

12,388. Are the men generally healthy ?—Extremely so. I consider that the underground men whom we have in our employ are by far the finest class in the country.

12,389. Do you think that they are stronger and finer men than the agricultural class ?—Decidedly so, infinitely superior to them as a rule ; I speak of the underground men. I attribute that partly to the fact of their being the finest class of men physically, but also to their earning higher wages than any other class in the country, and therefore being able to live better than any other class in the country.

12,390. (*Mr. Holland.*) Are they well lodged ?—Very well.

12,391. (*Chairman.*) How often are the men paid ? —We pay once a month.
